

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

## ONE HUNDRED AND TWENTY-SEVENTH SESSION, 1880-81.

### Council.

H.R.H. THE PRINCE OF WALES, K.G., *President of the Society.*

F. J. BRAMWELL, F.R.S., *Vice-Pres. and Chairman of the Council.*

H.R.H. THE DUKE OF EDINBURGH, K.G.,  
*Vice-Pres.*  
H.H. PRINCE LEOPOLD, K.G., *Vice-Pres.*  
F. A. ABEL, C.B., F.R.S., *Vice-Pres.*  
Sir RUTHERFORD ALCOCK, K.C.B., *Vice-Pres.*  
G. C. T. BARTLEY.  
GEORGE BIRDWOOD, M.D., C.S.I.  
THOMAS BRASSEY, M.P., *Vice-Pres.*  
R. BRIDENELL CARTER, F.R.C.S.  
ANDREW CASSELL.  
E. CHADWICK, C.B., *Vice-Pres.*  
B. FRANCIS COBB, *Treasurer.*  
Sir HENRY COLE, K.C.B., *Vice-Pres.*  
Sir P. CUSLIFFE-OWEN, K.C.M.G., C.B.,  
C.I.E.

LIEUT.-COL. DONNELLY, R.E.  
HENRY DOULTON.  
Sir T. DOUGLAS FORSYTH, K.C.S.I., C.B.,  
*Vice-Pres.*  
CAPTAIN DOUGLAS GALTON, C.B., F.R.S.,  
*Vice-Pres.*  
EARL GRANVILLE, K.G., F.R.S., *Vice-Pres.*  
Sir FREDERICK LEIGHTON, F.R.A., *Vice-Pres.*  
Sir JOHN LUBBOCK, BART., M.P., F.R.S.,  
*Vice-Pres.*  
REAR-ADMIRAL MAYNE, C.B.  
ADMIRAL Sir F. W. NICOLSON, BART.,  
C.B.  
EARL OF NORTHBROOK, K.C.S.I., *Vice-Pres.*

W. H. PERKIN, F.R.S., *Vice-Pres.*  
W. H. PERCE.  
ROBERT RAWLINSON, C.B., *Vice-Pres.*  
LORD REAY, *Vice-Pres.*  
B. W. RICHARDSON, M.A., M.D., F.R.S.  
OWEN ROBERTS, M.A., *Treasurer.*  
C. W. SIEMENS, LL.D., F.R.S., *Vice-Pres.*  
EARL SPENCER, K.G., *Vice-Pres.*  
WILLIAM SPOTTISWOODE, LL.D., P.R.S.,  
*Vice-Pres.*  
RT. HON. J. STANSFELD, M.P., *Vice-Pres.*  
DUKE OF SUTHERLAND, K.G., F.R.S., *Vice-Pres.*  
LIEUT.-COL. WEBBER, R.E.

### Secretary.

H. TRUMAN WOOD, B.A.

### Assistant-Secretary.

HENRY B. WHEATLEY.

### Accountant.

HOWARD H. BOOK.

### Auditor.

J. OLDFIELD CHADWICK.

## Arrangements for the Session.

The First Meeting of the One Hundred and Twenty-Seventh Session of the Society was held on Wednesday, the 17th inst., when the Opening Address was delivered by F. J. BRAMWELL, F.R.S., Chairman of the Council. Previous to Christmas there will be Four Ordinary Meetings, when papers will be read by Mr. J. Comyns Carr, Mr. A. G. Lock, Dr. Alfred Carpenter, and Mr. E. Price Edwards.

## Ordinary Meetings.

Wednesday Evenings, at Eight o'clock. For Meetings previous to Christmas :—

NOVEMBER 17.—Opening Meeting of the Session. Address by F. J. BRAMWELL, F.R.S., Chairman of the Council.

NOVEMBER 24.—“The Influence of Barry upon English Art.” By J. COMYNS CARR.

DECEMBER 1.—“Causes of Success and Failure in Modern Gold Mining.” By A. G. LOCK.

DECEMBER 8.—“London Fog.” By Dr. ALFRED CARPENTER.

DECEMBER 15.—“The Use of Sound for Signals.” By E. PRICE EDWARDS, Secretary to the Deputy-Master of the Trinity-house. On this evening Dr. TYNDALL, F.R.S., will preside.

### For Meetings after Christmas :—

- "The Photophone." By W. H. FREECE, Pres. Soc. Tel. Engineers.  
 "Buying and Selling; its Nature and its Tools." By Prof. BONAMY PRICE. On this evening Lord ALFRED S. CHURCHILL will preside.  
 "The Participation of Labour in the Profits of Enterprise." By SEDLEY TAYLOR, M.A., late Fellow of Trinity College, Cambridge.  
 "The Gold Fields of India." By HYDE CLARKE.  
 "Flashing Signals for Lighthouses." By Sir WILLIAM THOMSON, F.R.S.  
 "The Present Condition of the Art of Wood-carving in England." By J. HUNGERFORD POLLEN.  
 "Five Years' Experience of the Working of the Trade Marks' Registration Acts." By EDMUND JOHNSON.  
 "Trade Prospects." By STEPHEN BOURNE.  
 "The Manufacture of Aërated Waters." By T. P. BRUCE WARREN.  
 "The Compound Air Engine." By Col. F. BEAUMONT, R.E.  
 "Improvements in the Treatment of Esparto for the Manufacture of Paper." By WILLIAM ARNOT, F.C.S.  
 "Deep Sea Investigation, and the Apparatus used in it." By J. G. BUCHANAN, F.R.S.E., F.C.S.  
 "The Discrimination and Artistic Use of Precious Stones." By Prof. A. H. CHURCH, F.C.S.  
 "The Forests of India." By Sir RICHARD TEMPLE, Bart., K.C.S.I.  
 "The Tenure and Cultivation of Land in India." By Sir GEORGE CAMPBELL, K.C.S.I., M.P.  
 "Indian Agriculture." By W. R. ROBERTSON.  
 "Trade Relations between Great Britain and her Dependencies." By WM. WESTGAERTH.

### Foreign and Colonial Section.

The meetings of this Section will take place on the following Tuesday Evenings, at Eight o'clock :—  
 February 1, 22; March 15; April, 5; May 10, 31.

### Applied Chemistry and Physics Section.

The meetings of this Section will take place on the following Thursday Evenings, at Eight o'clock :—  
 January 27; February 24; March 24; April 7, 28; May 26.

### Indian Section.

The meetings of this Section will take place on the following Friday Evenings, at Eight o'clock :—  
 January 21; February 11; March 4, 25; April 29; May 13.

### Cantor Lectures.

The First Course will be on "Some Points of Contact between the Scientific and Artistic Aspects of Pottery and Porcelain," by Prof. A. H. CHURCH, F.C.S. Five Lectures.

The Second Course will be on "Watchmaking," by EDWARD RIGG, M.A. Three Lectures.

The Third Course will be on "The Scientific Principles involved in Electric Lighting," by Prof. W. G. ADAMS, F.R.S. Four Lectures.

The Fourth Course will be on "The Art of Lace-making," by ALAN S. COLE. Four Lectures.

The Fifth Course will be on "Colour Blindness and its Influence upon Various Industries," by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

### SYLLABUS OF THE FIRST COURSE.

#### LECTURE I.—NOVEMBER 22.

Bricks, tiles, terra-cotta, basaltes, and unglazed earthenware in general.

#### LECTURE II.—NOVEMBER 29.

Vitreous, plumbiferous, boracic, and felspathic glazes and enamels. Iridescent and metallic lustres, and colouring substances.

#### LECTURE III.—DECEMBER 6.

Stoneware and other wares glazed with salt.

#### LECTURE IV.—DECEMBER 13.

Soft paste porcelains, European and Oriental.

#### LECTURE V.—DECEMBER 20.

Hard paste porcelains, Chinese, Japanese, and European.

### Juvenile Lectures.

The usual short Course of Lectures adapted for a Juvenile audience will be given by G. J. ROMANES, F.R.S., on "Animal Intelligence." The dates for the lectures will be 29th December and 5th January. The lectures will commence at 7 o'clock. Special tickets will be issued for these lectures.

## Proceedings of the Society.

**CHARTER.**—THE SOCIETY OF ARTS was founded in 1754, and incorporated by Royal Charter in 1847, for "The Encouragement of the Arts, Manufactures, and Commerce of the Country, by bestowing rewards for such productions, inventions, or improvements as tend to the employment of the poor, to the increase of trade, and to the riches and honour of the kingdom; and for meritorious works in the various departments of the Fine Arts; for Discoveries, Inventions, and Improvements in Agriculture, Chemistry, Mechanics, Manufactures, and other useful Arts; for the application of such natural and artificial products, whether of Home, Colonial, or Foreign growth and manufacture, as may appear likely to afford fresh objects of industry, and to increase the trade of the realm by extending the sphere of British commerce; and generally to assist in the advancement, development, and practical application of every department of science in connection with the Arts, Manufactures and Commerce of this country."

**THE SESSION.**—The Session commences in November and ends in June. The number of Meetings held during the Session amounts to between 70 and 80.

**ORDINARY MEETINGS.**—At the Wednesday Evening Meetings during the Session, papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed.

**INDIAN SECTION.**—This Section was established in 1869, for the discussion of subjects connected with our Indian Empire. Six or more Meetings are held during the Session.

**FOREIGN AND COLONIAL SECTION.**—This Section was formed in 1874, under the title of the African Section, for the discussion of subjects connected with the Continent of Africa. It was enlarged, in 1879, so as to include the consideration of subjects connected with our Foreign and Colonial Possessions generally. Six or more Meetings are held during the Session.

**APPLIED CHEMISTRY AND PHYSICS SECTION.**—This Section was formed in 1874, for the discussion of subjects connected with Practical Chemistry and its application to the Arts and Manufactures. It was enlarged in 1879 so as to include the consideration of subjects connected also with the Applications of Physical Science to the Arts. Six or more Meetings are held during the Session.

**CANTOR LECTURES.**—These Lectures originated in 1863, with a bequest by the late Dr. Cantor. There are Three or more Courses every Session, and each course consists generally of from Three to Six Lectures.

**ADDITIONAL LECTURES.**—Special courses of Lectures are occasionally given.

**JUVENILE LECTURES.**—A short Course of Lectures, suited for a Juvenile audience, is delivered to the Children of Members during the Christmas Holidays.

**ADMISSION TO MEETINGS.**—Members have the right of attending the above meetings and Lectures. They require no tickets, but are admitted on signing their names. Every Member can admit two friends to the Ordinary and Sectional Meetings, and one friend to the Cantor and other Lectures. Books of tickets for the purpose are supplied to the Members, but admission can be obtained on the personal introduction of a Member. For the Juvenile Lectures special tickets are issued.

**JOURNAL OF THE SOCIETY OF ARTS.**—The *Journal*, which is sent free to Members, is published weekly, and contains full Reports of all the Society's Proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce.

**EXAMINATIONS.**—The Society's Examinations now comprise the following divisions:—1. Political Economy. 2. Domestic Economy—(a) Cooking; (b) Clothing; (c) Health; (d) Housekeeping and Thrift. 3. Music—(a) Theory; (b) Practice. 4. Elementary. The Programme for 1881 can be had on application to the Secretary.

**LIBRARY AND READING-ROOM.**—The Library and Reading-room are open to Members, who are also entitled to borrow books.

**CONVERSAZIONI** are held, to which the Members are invited, each Member receiving a card for himself and a Lady.

## Membership.

The Society numbers at present between three and four thousand Members. The Annual Subscription is Two Guineas, or a Life Subscription of Twenty Guineas may be paid.

Every Member whose subscription is not in arrear is entitled:—

To be present at the Evening Meetings of the Society, and to introduce two visitors at such meetings, subject to such special arrangements as the Council may deem necessary to be made from time to time.

To be present and vote at all General Meetings of the Society.

To be present at the Cantor and other Lectures, and to introduce one visitor.

To have personal free admissions to all exhibitions held by the Society at its house in the Adelphi.

To be present at all the Society's *Conversazioni*.

To receive a copy of the Weekly *Journal* published by the Society.

To the use of the Library and Reading-room.

Candidates for Membership are proposed by three Members, one of whom, at least, must sign on personal knowledge; or are nominated by the Council. The Annual Subscription is Two Guineas, payable in advance, and dates from the quarter-day immediately preceding election; or a sum of Twenty Guineas in lieu of all further contributions, may be paid.

All subscriptions should be paid to the Secretary, H. T. Wood, and all Cheques or Post-office Orders should be crossed "Counts and Company," and forwarded to him at the Society's House, John-street Adelphi, London, W.C.

### Calendar for the Session.

The following is the Calendar for the Session 1880-81. It is issued subject to any necessary alterations:—

The chair will be taken at eight o'clock at each of the above meetings, except the Annual General Meeting.

The Annual General Meeting will be held at four o'clock.

## NOTICES.

## THE PHOTOPHONE.

The paper on "The Photophone," by Mr. W. H. Preece, Pres. Soc. Tel. Engineers, announced for reading on the 1st December, has been unavoidably postponed until after Christmas. Mr. Alfred Lock's paper on the "Causes of Success and Failure in Modern Gold Mining," will be read in its place on that day.

## INDIAN SECTION COMMITTEE.

A meeting of the Committee of the Indian Section, was held on Monday, 15th inst, at 4 p.m., Present:—Mr. Andrew Cassels (in the chair), Dr. Birdwood, C.S.I., Sir George Campbell, K.C.S.I., M.P., Lord Alfred S. Churchill, Sir William Rose Robinson, K.C.S.I., Mr. J. T. Wood, with Mr. H. Trueman Wood, Secretary, and Colonel Hardy, Secretary of the Section. The programme of papers to be read during the present session was discussed and decided upon.

## PROCEEDINGS OF THE SOCIETY.

## FIRST ORDINARY MEETING.

Wednesday, November 17th, 1880; F. J. BRAMWELL, F.R.S., Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Alcock, Arthur Thomas, 5, Spring-gardens, Newark-upon-Trent.  
 Atkinson, Frederick William, 137, Leadenhall-street, E.C.  
 Aymer, Capt. John Evans-Freke, M.P., Aylmersfield, Streatham.  
 Baillie, J. H., 15, Old Bond-street, W.  
 Baxter, F., South Eastern-wharf, Park-street, S.E.  
 Bell, R., 83, Knight-ridge-street, E.C.  
 Bennet, Peter Duckworth, Edgbaston, Birmingham.  
 Biggs, Benjamin, 3, Lawrence Pountney-hill, E.C.  
 Blackwood, Richard, 96, Cromwell-road, South Kensington, S.W.  
 Blamires, Thomas Howard, Close-hill, Lookwood, near Huddersfield.  
 Blyth, James, 31, Park-terrace, Regent's-park, N.W.  
 Capel, Frank C., The Mount, Wilmington, Kent.  
 Carpmazel, Alfred, 1, Copthall-buildings, E.C.  
 Clark, William Timbrell, Kilsby, near Rugby.  
 Collington, James B., Beeston, Nottinghamshire.  
 Comerma, Capt. Andrés A., 48, Macfarlane-road, Shepherd's-bush, W.  
 Cotter, William Stokes, The Bank, Tottenham.  
 Cranwell, William B., 42, Portadown-road, W.  
 Crookenden, Isaac Adolphus, Marlborough-house, Blackheath, S.E.

Deane, James Parker, D.C.L., Q.C., 3, Paper-buildings, Temple, E.C., and 16, Westbourne-terrace, W.  
 Deaville, Rev. Joseph Gibson, Agincourt-villa, Bury, Lancashire.  
 Dewrance, John, 176, Great Dover-street, S.E.  
 Eaton, Francis James, Albert-road, Hosketh-park, Southport, Lancashire.  
 Emptage, Daniel, Dane-hill Sanitary Works, Murgate.  
 Estcourt, R. M., Local Government Board, S.W.  
 Evans, Lieut.-Colonel John, Highfield, Derby.  
 Ford, George Benjamin, 196, Westminster-bridge-road, S.E., and 9, Cuthill-road, Denmark-hill, S.E.  
 Freeman, William George, 44, Kensington-square, W.  
 Gordon, C. A., M.D., C.B., 70, Cambridge-gardens, W.  
 Grant, Sir John Peter, K.C.B., G.C.M.G., The Douns of Rothiemurhus, Aviemore, N.B.  
 Greenall, Lieut.-Colonel James Fenton, Lingholme, Derwentwater, Cumberland.  
 Guest, Montague J., M.P., 3, Savile-row, W., and Bere Regis, Blandford, Dorset.  
 Guthrie, Herbert, 32, Brown-street, Manchester.  
 Hall, Alexander Lyons, F.R.G.S., Lyon's-court, Lud-broke-road, Holland-park, W.  
 Harper, George Thomas, Southampton.  
 Harvey, William Charles, 12, Old-square, Lincoln's-inn, W.C., and 8, Warwick-road, Maida-hill West, W.  
 Haynes, F., Superintendent's Office, Telegraph Department, G.W.R., Taunton.  
 Heyworth, Lieut.-Colonel Lawrence, Wain Vawr, near Newport, Monmouth.  
 Hickman, Alfred, Goldthorn-hill, near Wolverhampton.  
 Homan, Ebenezer, Friern Watch, Finchley, N.  
 Hulse, Joseph, Dresden, Longton, Staffordshire.  
 Isaac, Benjamin, 102, Piccadilly, W.  
 Johnson, Walter Claude, Rivoli, Old Charlton, Kent.  
 Judson, Frederick Henry, 77, Southwark-street, S.E.  
 Keyser, Charles Edward, M.A., F.S.A., Morry-hill-house, Bushey, Herts.  
 Lambe, J. B., 199, Upper Thames-street, E.C., and 427, New-cross-road, S.E.  
 Lightfoot, Thomas Bell, 2, Granville-park, Blackheath, S.E.  
 Lingard-Monk, Richard Boughy Monk, 4, Westminster-chambers, S.W., and Fulshaw-hall, Wilmshlow, Cheshire.  
 Lovell, Richard J., 48, Oakley-road, Canonbury, N.  
 McDonald, James E., 4, Chapel-street, Cripplegate, E.C.  
 Marriner, William Tyler, Eton-villa, King Edward's-road, South Hackney, E.  
 Marshall, Alfred, The Villa, Muswell-hill, N.  
 Martin, John Cowdery, White Lead Works, Ossory-road, Old Kent-road, S.E.  
 Mineard, George Edward, 57, Warwick-road, South Kensington, S.W.  
 Moser, Charles E. Brooklyn, 75, Upper Tulse-hill, S.W.  
 Neal, James, 21, Lime-street, E.C.  
 Nyland, James, 42, Burlington-road, St. Stephen's-square, Bayswater, W.  
 Paddon, Samuel Wreford, Brooklyn, Chislehurst.  
 Pearson, Joseph Hickman, J.P., The Loveretts, Handsworth, near Birmingham.  
 Pfoundes, Charles, 1, Cleveland-row, St. James's, S.W.  
 Pickering, Charles William Harrison, J.P., New Brighton, Cheshire.  
 Pinnock, Henry, J.P., Beechwood, Newport, Isle of Wight.  
 Pursell, John Roger, Kingston-road, Merton, Surrey.  
 Puzey, William, 5, Aldermanbury-postern, E.C.  
 Quincey, Edmund de Quincey, 76, Avenue-road, Regent's-park, N.W.  
 Ravenscroft, Sidney Horace, Powis-lodge, Haverstock-hill, N.W.  
 Robinson, John, F.G.S., Kingscote, East Grinstead.  
 Robson, John, Tynemouth-road, The Green, Tottenham.  
 Rogers, J. H., Llanelly, Carmarthenshire.

Rothwell, Richard, 45, Holland road, Kensington, W.  
 Rudd, William Albert, Gloucester-house School Science  
 and Art Classes, Dodington, near Sittingbourne.

Simpson, George Palgrave, 2, Mount-terrace, Richmond, Surrey.

Ziegler, David, 7, Upper Woodland-terrace, New Charlton, Kent.

The CHAIRMAN delivered the following—

#### ADDRESS.

As no doubt most of you are aware, the By-laws of this Society make it necessary for the Chairman of the Council to retire from office after he has served for two years, and render him ineligible for re-assuming the chair until he has been away therefrom for at least one year. And thus it is, that we are deprived of the advantage of the chairmanship of Lord Alfred Churchill, who has so ably discharged, during the last two years, and on previous occasions, the duty of presiding over your Council. I am sure that, expedient as the By-law is, looked upon as a general law, applicable therefore to all, those who fully know, as the members of Council do know, the valuable services Lord Alfred Churchill has rendered to this Society by his assiduous attention to his duties, and by the high intelligence and extreme courtesy which he manifested in the discharge of them, will regret that, in his instance at least, the obligatory retirement enforced by the By-laws could not have been waived, so that we might have been able to say, "Oh, Chairman, reign for ever." Among all the members of this Society, none would have uttered that wish with more earnestness and with more sincerity than the member who now addresses you. But our laws, like those of the Medes and Persians, are inflexible in their application, and so it befel that, at the end of last Session, the chair became vacant.

I have received, from my colleagues on the Council, the unexpected honour of being selected as the successor to Lord Alfred Churchill, and thus it happens I have before me the task of addressing you on the opening evening of the Session 1880-81. I find in the performance of such a duty great difficulty, but being a duty, and one imposed by the By-laws, it must be fulfilled, and I will, therefore, without further preface than that of bespeaking your kind indulgence, proceed to discharge my task.

Your late Chairman, in one of his addresses, reminded you that when, in 1754 (126 years ago), this Society was founded, there existed none other which took cognisance of Arts, Manufactures, and Commerce. The Royal Society, established in 1660, was then, as now, engaged in the cultivation of pure science; and, indeed, it was not until some years after your foundation that Smeaton, the civil engineer, and a Fellow of the Royal Society, finding the need of an institution dealing with the application of science, originated that society of civil engineers now known as the "Smeatonians," a society which, from the first, was devoted to social purposes as well as to the discussion of engineering subjects; it is in the former capacity alone that it at present exists, having for its president of this year the engineer who is now Chairman of your Council.

Very different is the condition of things at this time. Institutions and societies abound on all hands. Indeed, it would be difficult to find a profession, or, in fact, an industry, which has not its own special society, or even, as in the case of the engineer, several societies. Civil engineering, in its wide and comprehensive aspect, is represented by the Institution of Civil Engineers, but branches of civil engineering have their separate societies—the Mechanical Engineers, the Naval Architects, the Telegraph Engineers, Mining Engineers, and others. Then we have the Institute of Architects, we have the Chemical Society, and more recently the Institute of Chemistry; and, in conclusion of this imperfect abstract of the list of learned societies, we have the comprehensive British Association. Among industrial societies, we have the Iron and Steel Institute, the Royal Agricultural Society, and others, not to speak of Chambers of Commerce. Not only has each profession its special society, but commonly also its own peculiar literature, such as journals devoted to engineering, to architecture, to medicine, and to chemistry. The industries likewise have their special literature; we have such papers as the *Miller*, the *Draper*, the *Jeweller and Metal Worker*, and I am told that there is a journal devoted to the profession or trade—I not know which to call it—of the pawnbroker.

You may remember that a late popular author took exception to the parade of system in the business of the publican, and, complaining of the inscriptions of "wholesale department," "retail department," and "jug and bottle department," suggested that the time would come when the subdivision would be still further extended, so that we should see written up "whisky bell" and "brandy entrance." I must confess I have a somewhat similar apprehension about the multiplication of societies for the consideration of branches of a profession; and I feel the day may come when there will be an institution for the civil engineering of piers, another for lighthouses, a third for docks, and a fourth for iron girder bridges. Up to a certain point, separate societies for branches of a profession, such as that of the Naval Architects, and of other already cited institutions as existing for branches of civil engineering, may be of advantage; but it is easy to carry the system of separation so far as to imperil the acquisition of the general knowledge of his particular profession as a whole, which a thoroughly competent professional man should possess.

But without speculating further as to the future development of special societies, it is clear a sufficient number already exist to give occasion to some among the outside public, who have not been at the pains to consider the subject, to ask what is now the necessity for a Society of Arts? What functions remain to it in relation to Arts, Manufactures, and Commerce? Do not the special societies cover all the ground, and are they not, being special, in a better position to do good work, each in its own line, than can be done by a society like yours, which has no speciality? Such suggestions, adverse to our continued utility, may find favour on a first hearing among those who do not know the working of our Society, and who will not be at the pains to learn what that working is, before they come to a determination in their own minds upon the question, but we, the members, know better. We are aware that there is a very wide field for the work of this Society—a field unoccupied, and of necessity unoccupied, by the special societies which have sprung up. For instance, we must all agree it is for the good of the country at large that men and women, wholly unconnected with particular industries, except (and it is a most important exception) in their capacities of consumers, should have a general knowledge of how those things they consume are produced. I will ask how, without the existence of the Society of Arts or of some kindred society, would it be possible for this large section of the public to obtain such general knowledge. By the hypothesis, these persons are not specialists, and, therefore, they are not eligible as members of these special societies. Moreover, in the comparatively rare cases, where a man is eligible for membership of one society, he cannot be eligible for membership of all; and, further, if a non-specialist attend the meetings of a special society, he will find in all probability that its deliberations are not relating to broad generalities, such as the non-specialist wants to hear discussed, but that they are concerned, and properly so, with considerations of detail—of those details which may appear of but small value to the ordinary hearer, even if he can understand them, but to the patient accumulation of which the improvement in an art is much more commonly due than it is to some one great discovery.

At our meetings, as I have said, the audience profit by having presented to them, in a comprehensive and intelligible form, the leading facts connected with our important industries, thereby the range of knowledge of all is increased and interest is excited; moreover, this very important end is attained, that those who are thus instructed become intelligent purchasers, a desirable result not only for those who purchase, but for those who manufacture, since the intelligence of the purchaser raises the standard of the manufacture. I will refer to a recent instance, that of the admirable course of Cantor Lectures delivered here by Mr. Bolas on the "India-rubber and Gutta-percha Industries." I do not hesitate to affirm that the hundreds who heard those lectures, and the thousands who read them in our *Journal*, became thereby discriminating purchasers, to their own benefit and to the benefit of the honest producer.

At the risk of being open to the charge of quoting myself, in remarks I delivered in this room some

years ago, upon the Patent-law, I must point out another, and, to my mind, a very important particular, in which the bringing the processes of manufacture before persons not having any special knowledge thereof is useful, and that is the aid afforded to substantive invention. By substantive invention, I mean an invention which changes fundamentally the process of a manufacture, as distinguished from inventions of improvement in detail in the manufacture as hitherto carried on. Those who are imbued with a specialist's knowledge have a difficulty in taking a thoroughly new view of a manufacture; paradoxical as it is, they are encumbered with their own too intimate knowledge of every existing step and detail. In the paper on the Patent-law, to which I have alluded, I gave certain instances of well-known substantive inventions, all of which had been made by men having no previous connection with the industries to which those inventions related. I will not take up your time by repeating any of them here, but I will, with your permission, give the following instance—an instance that has come to my knowledge since the date of that paper. Fortunately, in the interests alike of the makers and the wearers of boots and shoes, a certain inventor, when he set himself to invent a machine for sewing on the soles of boots and shoes, had no previous knowledge of the manufacture, except that wherein rivets were used. He knew what an ordinary sewing machine was like, and he, of course, knew the outward appearance of a sewn boot. Luckily, as I have said, he had not studied that part of the shoemaker's art which related to the attachment of the sole by sewing. It occurred to this inventor that it would be a very desirable thing if a sewing machine could be made so compact that the necessary working parts could be introduced up the leg of a boot, and to the very extremity of its toe, and, when there, could be driven in the needed and imperative unison with the machinery exterior to the boot. The inventor solved the problem, and made a machine, the necessary portion of which could be inserted into the toe of a boot, and could be worked there, but this machine would not have been of the slightest use in sewing a sole to a boot in the manner in which that operation had up to that time been conducted by hand, although it was of every use in the sewing on of a sole by the process which the inventor, in his happy ignorance, believed to be followed.

In the ordinary hand-made boot, the upper leather is not fastened to the sole directly, but has sewn to it a bevelled strip on each side, which is called the "welt." It is this welt, and not the upper leather, which is united to the sole, and thus, although the hand cannot be got to work within the boot, the union of the upper leather to the sole is effected through the medium of the welt. The inventor, however, considering the whole subject with an untrammelled mind, assumed that the reasonable way to secure the upper leather to the sole was to do so directly, and without any go-between. Now, everybody who knew the art and mystery of shoemaking had, a trammelled mind, he had it engrained in his very being, that in all cases where thick and comparatively rigid soles were sewn on, welts were indispensable. I will ask you to imagine to yourselves the impediment that this reverence for the welt must have

been in the way of any man thoroughly understanding the shoemaking business, and endeavouring to use sewing machines for the purpose of attaching the sole to the upper leather. Such a one would get as far as the sewing of the welt to the upper leather by machinery but there he would be stopped from any attempt to devise a machine to work within the boot, and for the very obvious reason, that having sewn on the welt, he would, of course, use that welt for the purpose for which he had sewn it on, namely, that of effecting the union of the upper leather to the sole by stitches, not from within the boot at all, but entirely external thereto. I have seen the evidence which the inventor prepared to offer before the Privy Council, and he there declares that had he known the details of the way in which the upper leather is sewn on to the sole, he would never have ventured to solve the problem. The inventor, of whom I have hitherto been anonymously speaking, is Mr. Blake, an American, and I was informed only yesterday, through the representative of the Blake Company, that one hundred millions of pairs of boots and shoes were sewn last year on the Blake machines. I have devoted, I fear, to the subject of boot-sole sewing machines too large a proportion of the total time allotted for this address; but I have been induced to do so because I believe the circumstances I have narrated afford a fair instance of the benefit which invention derives from the attention of intelligent non-specialists being directed to the broad and general features of a manufacture, in the way in which it is directed in the papers and lectures read and delivered within this room.

Another use of our Society is this—we afford an appreciative home to new arts and industries. The Royal Academy itself, which was founded in 1768, owes its inception to the first exhibition ever made of the pictures of British artists in 1760, and repeated in following years, in the rooms of the Society of Arts. Again, in 1852, photography came to us as a new-born art, and one without a home; that foundling was taken in by the Society of Arts, and, being nourished, has grown up to vigorous manhood. We will hope that invention and discovery are not at an end, and that, from time to time, new arts and industries will arise. As they come into existence, it is all but certain they will need shelter and encouragement, and sure I am that so long as this Society is to the fore, those needs will not remain unsatisfied.

Without taking up your time by further specific instances of the way in which our Society has a right to its place, notwithstanding that there are so many special societies and institutions, I may refer objectors to the answer contained in the old saying, "That there is nothing so successful as success," and if they dared to dispute our being successful, they would certainly be defeated. We can point to the fact that we number over three thousand members, that we have institutions all over the country in union with us, that we publish a weekly *Journal*, circulated gratuitously among those members and institutions, by which they and the public at large are kept fully informed of the condition and progress of our leading manufactures, that we have been fortunate enough to be favoured with the recognition of the

Prince of Wales, who honours us by being our President, and that we succeed in obtaining in the guidance of our work the untiring assistance at the Council of men eminent in the most varied ways.

With respect to the work we do, some of our critics say that we occasionally, indeed not unfrequently, occupy ourselves with matters which, wide as is the scope of the Society's operations, as stated in our Charter, cannot be brought properly within the pale of Arts, Manufactures, or Commerce. For instance, the Society takes up Drill. They say if drill mean a certain textile fabric commonly used for male garments, well and good; if it mean the implement for making holes, either in the soil or in metals, equally well and equally good; but if it mean, as in truth it does, the training to which soldiers are subjected, how, by any possibility, can that drill be connected with arts, manufactures, or commerce? What have "shoulder arms," to do with arts? "Right about face," with manufactures, or "quick march," with commerce? "Shoulder arms" suggests hard angularity, and nothing in connection with arts, or art; "Right about face" is opposed to the steady and forward progress that should be made in manufactures; and "Quick march" is more applicable to mere speculation, than to the sound prosecution and regular progression of legitimate commerce. Apparently valid objections these, but see how they disappear before the explanation given by the advocates of drill. They say, to have excellent manufactures, you must have excellent workmen—you must cultivate not only their minds, but also their bodies. You want manly men, men whose powers are developed, and who are trained to apply those developed powers in the best manner. An excellent means to this end is in early life to give the training of drill, resulting in that which we all know as a soldierly bearing; a lad who has once acquired this will hardly ever in after life entirely lose it, but he will go about erect, self-reliant, and self-respecting, and for the whole of his life will be a better man than one who, undrilled, slouches through existence. Should the critics still be dissatisfied, and say the link you show between drill and manufactures is too slender, the argument is more ingenious than sound, and should they urge that public bodies ought to keep more rigidly to the undoubted objects for which they were incorporated, the supporters of drill can refer to a precedent of very high authority—a precedent which, with your permission, I will quote to you. In a certain island, the latitude of which I will not state, and the longitude of which I cannot state, because to the English mind it is of no longitude, there were established in years gone by, three principal Courts of law, the names of which, curiously enough, may be not unfamiliar to you. The first was called the King's Bench; it took cognisance of affairs affecting the dignity and peace of their lord, the king. The second was called the Court of Exchequer. This Court took cognisance of all matters affecting the king's revenue. The third Court was called the Common Pleas, and it took cognisance of complaints between subject and subject. While the population was scanty and rude, business transactions were but few, and the Court of Common Pleas was the least occupied of the three; but, as time went

on, the people increased in number and in wealth, and became more civilised. Offences against the king's peace, and frauds upon his revenue, happily for the public, diminished in number, while business developed, and, as a result, transactions became complicated, and plaints between subject and subject grew and multiplied. The Court of Common Pleas naturally was in a very flourishing condition, and those connected with it thrived upon the fees paid by the suitors; but the Courts of King's Bench and Exchequer, although they retained their dignity, found themselves excluded from the pecuniary benefits enjoyed by the Common Pleas. This went on until an ingenious member of the Court of Exchequer, prompted by necessity, found the connecting link by which that Court was enabled, of course strictly within its functions of guarding the king's revenue, to take cognisance of plaints between subject and subject. The link was this. Subject A should pay the king his taxes, but if subject B did not pay to A the money which B owed to him, A obviously would not be likely to pay the taxes to the king, thereupon, quite within its province of course, it became incumbent on the Court of Exchequer to ascertain whether B did owe A a sum of money, and thus the Court of Exchequer investigated plaints between subject and subject. The unhappy King's Bench, however, was still left out in the cold, a cold by comparison all the more disagreeable to bear because its colleague, the Court of Exchequer, had succeeded in withdrawing itself into a comfortable shelter. At length the genius needful to supply the connecting link for the Court of King's Bench was found. That Court, you will remember, took cognisance of all matters affecting the king's dignity and peace. Said the ingenious man of the Court of King's Bench, I know nothing much more likely to cause a breach of the peace than the refusal to pay a just debt. If B owes A money, but will not pay A, such is the infirmity of human nature that A is very likely to cudgel B at the first convenient opportunity. To prevent this breach of the King's peace, it is clearly the duty of the Court of King's Bench, and strictly within its functions, of course, to take cognisance of the plaint between subject A and subject B. Whether this tale is a strictly true one, or whether it has only a foundation of truth, and that as regards its details the Islander from whom I received it was imposing on my credulity, I won't pretend to say, but it seemed to me not wholly inapplicable to the subject we were considering, and that the advocates in the Society of Arts for the promotion of drill, if they can't convince by their argument, may, at all events, crush their opponents by the weight of the precedent I have just quoted.

Having regard to the undoubtedly wide scope afforded us by our Charter, and to the probable increase of that width by ingenious reasoning and by precedent such as I have cited, you can well understand that there are very few subjects indeed in respect of which a connection with the purposes of this Society may not be traced, or, at least, imagined; and thus it is that your Council have to exercise great discrimination in the acceptance or non-acceptance of the various suggestions that are made to it, as affording proper subjects for the action of the Society. Brown would have all our

energies devoted to the obtaining of a soft water supply for the kingdom at large; millions of money would be saved in soap, and millions more in tea. Jones is convinced that water supply is indeed the only fit subject for the Society, but urges that the water must be hard if we desire to avoid lead poisoning—if we wish for a delicate cup of tea instead of a dark and bitter family brew, and above all, if we desire to see the rising generation furnished with bones, and are not content that they should be simply cartilaginous animals. Robinson believes that the true present work of the Society is to see that all sewage is disposed of by irrigation; while Smith, although agreeing that the disposal of the sewage is the only true work, is clear that irrigation is but another name for the spread of disease, and that salvation lies in precipitation. Others would have the Society neglect everything until it had achieved the introduction of the decimal system, and of the French metrical system in particular. Government must come to the rescue. Decimals must be obligatory. They would have no half measures; I beg their pardon, no nought decimal five measures; they would show no quarter—again I err from the right way, I mean, of course, no nought decimal two five—to those who dare to use that complex term, one-third, instead of the simple and nearly accurate expression, nought decimal three three three and a little dash in the right-hand corner; still less would they forgive those who employ, in describing the division of anything into seven equal parts, the wholly unintelligible and cumbersome one-seventh, instead of the concise and elegant (and again nearly accurate) nought decimal one four two eight five seven, and again the little dash in the right-hand corner. The foregoing are but instances—instances of demands which may come from the outside public, from the members of the Society, or, I speak it with reverence, even from the members of the Council itself. Probably some of us have now, as people had in Mr. Shandy's time, our little hobbies on which we would fain disport ourselves; but, happily for the Society, we are not allowed to do so, unless the hobby is proved to be discreet and trustworthy. The check to our vagaries is this: our Council, as I have told you, is composed of men of varied pursuits, the soldier, the legislator, the sailor, the engineer, the chemist, the physician, the Government official, the potter—*emphatically the potter*, for I allude to our friend Mr. Doulton, to whom we owe a new art industry, of which England is justly proud—and many others, go to make up your Council. And though, as I have said, some of these, including, it may be, their chairman, have each his own little hobby, in the sure-footedness of which he implicitly believes, he is not thereby rendered incapable of perceiving the defects in his neighbour's favourite steed. All banter apart, your Council is well attended by men of divers qualifications, and no plan brought before that Council is made the subject of the action of the Society, unless the plan, after thorough scrutiny, commends itself to the good opinion of the majority. Care has also to be exercised in the acceptance of papers, to ensure that not only shall the subjects be of sufficient interest in themselves, but that they are free from any

suspicion of partisanship, or of trade puff. In this work, as indeed in all other matters, the Council are greatly aided by our most attentive and careful secretary, Mr. Trueman Wood, whose connection with this Society, first as assistant secretary to our late and valued friend Mr. Le Neve Foster, and since his death, as secretary, has now subsisted for eight years. On the whole, looking at the innumerable temptations there are to stray, I think the Society is to be congratulated on having kept very fairly within its proper boundaries, and I know I am safe in assuring you that no pains will be spared by your Council, nor will any amount of time and attention be grudged to ensure that good and useful work shall continue to be done.

Thus far, I have been reviewing some of the past action of the Society, and, in doing so, I have had of necessity to bring to my own recollection the nature of many propositions laid before the Council by ardent persons, but properly rejected as being visionary, or as not within our true functions. And such recollections have tempted me here and there to stray too far from the sedateness that has characterised, and that some of you will think ought always to characterise, the annual address. I fear it will be said that if there be some grains of valuable truth to be found in that which I have laid before you, these grains are very deeply concealed beneath the husk, not to say chaff, with which they are intermingled and overlaid. In considering, however, the future work of the Society which I am now about to do, I find no temptation thus to stray from strict decorum, because I feel that to that future work we ought to devote our best efforts and most grave attention, and because I have to bring before your notice much that is painful and humiliating.

However laudable are those efforts of the Society for the promotion of subjects which have not an immediate, but only a remote bearing on the welfare of Arts, Manufactures, and Commerce, I, for one, am better pleased when I find we are occupied with subjects which do undoubtedly directly and obviously bear upon that welfare; and I am sorry to say that there is an ample field for such occupation in the present condition of our manufactures.

Many of you have, no doubt, read the address delivered at the summer meeting of the Mechanical Engineers by the President, Mr. E. A. Cowper. In that address, Mr. Cowper gives instances of the way in which foreigners not only compete, and rival the manufacturers of this country, but surpass them and outstrip them, and it is to this question I desire now to direct our thought. I am aware this is not a pleasant subject. I should have been glad indeed, if, on the first night of our Session, I could have followed many of my predecessors, by talking to you of progress and of success. Depend upon it, it is more agreeable to the occupant of this chair to prophesy pleasant things, than it is to prophesy evil things, but, nevertheless, there can be no doubt which of these two courses is that of duty, and that course, and not the other, is the one that must be followed.

With respect to this question of being beaten by our rivals, very varying feelings are excited as we consider the circumstances attendant upon our defeat in each particular case; for instance, we do not

even regret that an industry, which is an exotic, and not natural to the country, fails us, and reverts to its more proper home. As an extreme example, it is recorded that, long ago, it is true, wine was made from a vineyard on Tower-hill. No one, I presume, seriously laments that efforts have not been made to continue such an industry as this in England. We are well content that it should depart to countries possessing a more genial climate than that in which we live.

We do regret, and complain, but we do not feel ashamed, when an industry, properly within our province, is caused to wither by the mistaken action of the Government of another country, in pampering such an industry within that country by bounties and premiums, against which our manufacturers cannot contend. We are not ashamed of being beaten under these circumstances, but do our best by protest, and, by all means short of a retaliative duty, to put a stop to so mischievous a procedure. But we lament, and that with a mixture of shame, when we find that, in the absence of any such adverse influence as that arising from bounties in foreign countries, industries which are thoroughly adapted to the climate and the soil, and, worse than this, industries which should, from our natural advantages, be specially our own, are carried on in foreign countries in a manner not only to rival us in these countries themselves, and in the markets abroad, but so as actually to successfully compete with us on our own shores. Surely in iron and in steel manufacture, intimately connected as the success of these manufactures is with the cheapness of fuel, we ought to be able to defy competition in any open market, and yet we know that large quantities of girder iron are habitually imported into this country from Belgium. This importation of iron from Belgium is but one instance; it is, I regret to say, by no means a solitary one. Surely there must be something wrong in our conduct of manufacture, when such a state of things can exist, and I believe the Society of Arts will do well to endeavour to ascertain what this something wrong is, and having ascertained, it will do well to set itself to endeavour to find a remedy for the wrong.

I will not venture to predict what would be the result of investigation into the causes of this condition of things, but one can imagine we shall find higher rates of wages operating in some cases, but certainly not operating in those instances where we are beaten out of our own markets by American manufacturers, for in that country, undoubtedly, wages are higher, as a rule, than they are with us, and there are three thousand miles of transport needed to bring the manufactured article to our doors. We shall find, it may be, that many of our industries are carried on according to the old traditions, traditions of practices which were the best known in the days when they were first employed, but which, under the teaching of science in other countries, have been abandoned as obsolete, while they are retained by ourselves. We may find, paradoxical as it appears, that the fact of our having been engaged in any particular manufacture for many years obstructs our readily adopting the most improved forms of carrying on that manufacture, and obstructs it, for I am again about to quote myself, in a way that I pointed out when speaking on the question

who pursue it, the advantage of expending capital upon the newest and best plant by carrying on the manufacture, and upon that point, while those who have carried it on for a long country cannot put themselves on a par with their new rivals, unless prepared to abandon the whole of the plant which has been embarked in, and must become obsolete, if the new process is to be adopted. This is a serious drawback; few have the means to effectually assist those who have, very naturally feel rather to retire from an industry which, successful pursuit, requires to be in effect new, and even to be learnt anew, than to stir savings in the necessary plant for this manufacture.

But there will be found, and I fear there is found, but I do trust in only a few instances, that we have lost command of foreign and even of our own markets, because in some instances the manufactures have not been so good. There was a time, when travelling on the continent, one was proud to see English manufactures forwarded as those to be thoroughly good. A foreigner felt that if he bought an article made in England, though it might not be tasteful, it would be what it purported to be, honest, and trustworthy. I am afraid we now say so of all that is exported from England, or that is offered for sale within it. I

we can say so of most of our manufactures, but we certainly cannot say it of all. It should be remembered as against those who utter this grievous wrong of casting a slur on the character of any of our industries that they do not harm to the particular manufacture with which they are connected, but they do harm to the character of the whole produce of the nation. One who has been trapped into buying a bad product of one kind, is not at the time able to ascertain whether the badness is confined to this particular manufacture, and in all

harm by diminishing the nourishing or the curative power of that which was purchased, but fraud which extended to the mingling, in some instances, of materials which were, in themselves, actively unwholesome, materials which, being taken with the food, converted the food into a source of disease, and being taken as curative drugs, converted those drugs into positive poisons.

Is it not too much to be feared that, in some industries, at all events, that reprehensible conduct which has rendered necessary the appointment of public analysts to protect the population of this country, has been the guide of certain of the manufacturers, and has thereby caused us to export that which is a fraud upon the foreign buyer, and a discredit and an injury to the country that exports.

I had intended to refrain from instances, but I will endeavour, in general terms, to state one which relates to a very large industry. It appears that in a certain manufacture the purchasers preferred to buy goods that were dyed in one stage of the process rather than in another, as the goods thus dyed were supposed to be better, and they naturally, therefore, commanded a higher price. The finished goods bore on themselves indications which enabled any purchaser, at all acquainted with the manufacture, to determine at a glance in which of the two ways the article offered to him had been dyed. Then came the deceit. Means were adopted by which the appearance that would have been presented, but for these means, upon the material dyed in the undesirable way, was concealed, so that the appearance really presented was that which would be shown by the manufacture when dyed in the desirable way. It is true that experts in the trade can, after the deceit has been employed, distinguish the one fabric from the other, but the ordinary buyer living abroad, and not suspecting the fraudulent ingenuity that had been exercised in England, and seeing, as he believes, the well-known appearance indicative of the superior mode of dyeing, is deceived, and pays a higher price than he would have paid had he known

of our defeat is due to the way in which we receive and deal with inventors and inventions.

I hardly like to approach this subject at all, because on previous occasions I have, through the kindness of the Society, been allowed to occupy many hours of their time in putting forward my views upon it, and in combatting the views of others, but I am nevertheless tempted to ask you to bear with me while I say a few words upon the question, because I most earnestly and sincerely believe in its importance in relation to manufactures, and because I trust there is to be gathered a hope of a change for the better in public opinion concerning it. From a statement appearing in the *Times* of the 12th inst., there is good reason to hope that the President of the Board of Trade is himself desirous of an improvement in the laws. The paragraph is as follows:—

"MR. CHAMBERLAIN AND THE PATENT LAWS.—A communication on this subject has been addressed by a gentleman in the North of England to the President of the Board of Trade, whose secretary, in his reply, alluding to a recent speech of Mr. Chamberlain's, says:—"I am desirous to call your attention to the fact that he (Mr. Chamberlain) was not in a position to promote the amendment of the law, as the possibility of doing this depends upon the condition of public business, and upon the character and extent of the opposition with which the proposals of the Government may be met in the House of Commons. Mr. Chamberlain hopes, however, that time may be found before long for the consideration of the subject, and, as far as his personal opinion goes, it is strongly in favour of removing or lessening the obstacles which now interfere with and discourage invention in this country."

Before any real good can be attained by altering the Patent-laws, it is necessary that those who are charged with the framing of the alteration should consider the question of patents in a totally different light from that in which, in times past, and nearly up to the present time, that question has been considered. Hitherto the framer of a Patent Bill was expected to prepare it on the supposition that on the one side were the public, and on the other the enemy of the public, the inventor, against whom the public, by the ingenuity of the framer of the Bill were to be protected. I submit the true spirit in which the revision of the Patent-laws should be approached is to understand that, on one and the same side, and not in opposition, are the public and the inventor, and that the object of the new law should be to afford that protection to both which would result in benefit to the public and in a fair reward to the inventor.

The popular impression is (I wish I could say "was") that directly an invention connected with an industry is published, all engaged in that industry would use the invention, and thus the manufacture, and through it the population at large, would benefit, were it not that this benefit is delayed for fourteen years because of the patent protection given to the inventor. But the truth is, that so far from manufacturers desiring to adopt an improvement, they would desire nothing better than that their manufacture should have reached the point where improvement is impossible, and where they could sit down and say, "we are up to the very acme of perfection in all our plant and machinery, and in our knowledge of the business. We have no change to apprehend. We can carry our works on as a set trade, and we

price, or on that of quality, or on the score of the higher knowledge possessed, or the better taste displayed abroad. If it be on account of price, let us find out whether the disparity arises principally from the labour question, or whether it arises, as it must do in countries where labour is dearer than in ours, from the use of improved processes in those countries—processes which we have failed to employ.

Again, where we find that the cause of our defeat really does lie in difference of wages, let us see whether it be not possible to improve the application of machinery to such a point as shall render the wages question unimportant compared with other considerations which may be in our favour.

I have sufficient confidence in the skill and ability, and in the amount of capital available in this country, to believe it needs only that the true causes of the success of our competitors should be discovered to make us effectually bestir ourselves to restore the threatened industry to its former safe position.

If we find the superiority of the foreigner to be due to the judicious encouragement and adoption of invention, then I trust that matter will ere long be set right by the promulgation of new Patent-laws, framed on sound principles.

I have hitherto spoken of those industries wherein successful competition has already seriously affected us. But there are others, of course many others, in which we still hold our own, and hold it well. Among these is that of the “carrying trade.” No one can read the records which from time to time appear in the papers, of the magnificent steamers which are being built, and year by year are increasing in size and carrying capacity, without feeling a sense of gratification, that on the sea, at all events, England is holding, as she ought to hold, her own. You will have noticed that these steamers have long since ceased to be built of wood, and that iron has been the material employed. You will also have noticed that now gradually, although very gradually, iron is being superseded by steel. It may not be generally known to you, but it is the fact that the United States are now producing enormous quantities of Bessemer steel. The Americans, it need not be said, are hardy mariners, they are daring naval architects, and it only remains for them to have money a little cheaper (and it is becoming cheaper day by day), and to get rid of some of their own restrictive duties, to enable them to apply a portion of this surplus steel to the building of steamers which will enter into competition with our own. Depend upon it, that when such rival steamers are started, every invention tending to economical management and working, and especially, therefore, to the saving of fuel, will be adopted in their ships. And thus it behoves our shipowners and merchants (as well as our manufacturers) to watch all improvements as they are brought forward, to adopt them if sound, and not to wait until the adoption is forced on them, because they find their rivals have already used the improvements, and are thereby enabled to obtain a preference in the ports to which they trade.

I suggested it might be found that a cause of successful competition against us in certain manufactures, arose from a want of knowledge

or from a want of taste in those engaged in the same manufacture in our own country. I do not mean the mere rule of thumb knowledge, but the knowledge of the scientific principles involved; and upon this point, although I feel I have trespassed on you at too great a length, I will ask your indulgence for a short time—a very short time. I am one of those who believe that for a manufacture to be carried on successfully under all circumstances of change which may arise, those engaged in it, the principals, managers, foremen, and leading workmen should have a knowledge of the scientific or artistic principles involved in the carrying on of that manufacture. The Society of Arts has long entertained these opinions, and is to be commended for having, in furtherance of them, in the year 1872, established those Technological Examinations, which it adopted in the absence of any machinery for technical teaching to lead persons to educate themselves, so that they might come forward and submit to an examination by competent examiners, and thereby prove their fitness for the position that they occupy.

These examinations were continued until they became a heavy burden upon the resources of the Society, and their utility having been thoroughly established, they were in the condition in which the Society could properly hand them over to any other body competent to undertake them. As most of you are aware, about two years ago, certain of the Livery Companies of London associated themselves together and established the City and Guilds of London Institute for the Advancement of Technical Education. That institute, which was duly incorporated on the 9th of July last, has, amongst its other works, taken over—now for two years—the Technological Examinations of the Society of Arts. In the outset, the institute was aided in the carrying out of this work, by the counsels of your Secretary, Mr. H. Trueman Wood. The result of the two years' working, has been of the most gratifying character. In 1879, there were in all 202 candidates examined in 7 industries, of whom 161 passed in some one of the grades. In this year there were examinations in as many as 24 industries, and in these 816 candidates were examined, and 615 passed in the various grades.

The City and Guilds Institute is carrying on—I won't detain you with the details of what it is doing—technical instruction in many other ways. It has schools of applied art at Kennington, and applied science classes at Finsbury, where it is preparing to erect a building, at a cost of £20,000, to afford more room for its operations. It has contributed towards chairs of fine art, applied mechanism, applied chemistry and metallurgy, in King's College, and in the University College, London. It has helped the Artisans' Institute, it has helped the Society for the Employment of Women, and it has assisted other educational bodies in the country. Moreover, it has obtained a lease of ground for 999 years, at a nominal rent, from her Majesty's Commissioners of 1851, on which there is about to be erected a central institution, from the designs of Mr. Waterhouse, the eminent architect.

During the autumn vacation, I paid a visit to the Polytechnic Institution at Zurich, established in pursuance of a law passed in 1854. I found there a building of about 445 ft. long by

idea, with a central court-yard. I was this building, containing, as it is stated, million cubic feet of available space, had including two small detached buildings) francs, or practically £100,000 sterling, taught between 800 and 1,000 students, whom I found, by the returns, that there was a proportion of 349 from countries other than Switzerland, and included in these Great figures for 5 students. This establishment cost at a cost of 455,000 francs, or £18,200 a year. Of the revenue, which is slightly of the expenditure, about £3,800 is derived from 'dents' fees, at 100 francs per head per except in certain cases, where the instruction is quite gratuitous; £13,800 comes from £800 from the Canton of Zurich and town of Zurich, and about £120 from scripts. I felt, I must confess, thoroughly that a comparatively poor country like and, having a total population, according to census, of considerably less than three should possess an institution of this kind, while in England it is difficult to point instance of any such institution at all, and twenty-five years after the example was in Switzerland, we are about to establish in, at last, a central institution which, we regard the magnitude of the building, number of scholars, or the number of to be taught, will represent but a fraction as at Zurich. But, nevertheless, a small is better than no beginning at all. I have confidence in the result of this on the part of the City and Guilds of Institute. We have hard-working men on every body, among whom are to be found, to say, the President of the Royal Society, President of the Institution of Civil Engineers, President of the Chemical Society, and the member of the Council of the Society of Arts. In the present instance, the City and of London Institute do not possess in this need official an extra adviser, because it so that your present Chairman of Council is Chairman of the Executive Committee of City and Guilds of London Institute. In when it was resolved to ask the advice instance of the Chairman of your Council, Lord Alfred Churchill was in office, but before the City and Guilds Institute was incorporated, and into actual operation, Lord Alfred Churchill to resign, and I came in his stead, so that City and Guilds of London Institute have after ved themselves (as was to be expected) every sportsman, for they have shot at a and they have brought down a crow. I am lapsing into that unseemly levity in indulged in the early part of this evening; that ground, even if not on the ground of ness of the hour at which we have arrived, prudent I should bring my address to a conclusion, and I cannot more fitly do so than by ig you for the attention with which you are good enough to listen to it, and by once reminding, in the name of the Council, whose in I have the honour to be, that every effort made throughout the coming session, as been made in times past, to promote the s of the Arts, Manufactures, and Commerce

of Great Britain, and thereby to promote the interests and welfare of this Society.

Lord Alfred S. Churchill proposed a vote of thanks to the Chairman for his excellent address, which contained a most luminous statement of the aims and objects of the Society; and he thought the members must congratulate themselves that so distinguished a man held the position of Chairman of Council.

Mr. W. Botly, in seconding the motion, remarked on the interesting programme prepared for the coming Session, and alluded to the long list of candidates proposed for election. He thought they might all help in promoting the objects of the Society by obtaining new members for what he considered one of the most instructive institutions in existence.

Sir Antonio Brady supported the motion, and, as President of the Inventors' Institute, expressed his particular approval of that part of the address relating to the improvement of the Patent-law.

The vote was carried unanimously.

The CHAIRMAN then presented the following medals and prizes, awarded during the past session:—

The Society's Silver Medal:—

- To Major-General H. Y. D. Scott, C.B., F.R.S., for his paper on "Suggestions for dealing with the Sewage of London."
- To A. J. Ellis, F.R.S., for his paper on "The History of Musical Pitch."
- To JOHN SPARKES, for his paper on "Recent Advances in the Production of Lambeth Art Pottery."
- To HENRY B. WHARTLEY, F.S.A., for his paper on "The History and Art of Bookbinding."
- To W. HOLMAN HUNT, for his paper on "The Present System of Obtaining Materials in use by Artist Painters, as compared with that of the Old Masters."
- To THOMAS FLITCHER, for his paper on "Recent Improvements in Gas Furnaces for Domestic and Laboratory Purposes."
- To JOHN C. MORRIS, for his paper on "The Last Forty Years of Agricultural Experience."
- To Prof. HEATON, F.C.S., for his paper on "Belmain's Luminous Paint."
- To Captain ARNRY, R.E., F.R.S., for his paper on "Recent Advances in the Science of Photography."
- To J. W. WOOD, for his Leak Stopper for the Protection of Ships from Sinking.

His Royal Highness the Prince Consort's Prize of Twenty-five Guineas, to WILLIAM CLARKE HUDSON, aged 25, of the Liverpool Institute, student, who has obtained the following First Class Certificates at the Society's Examinations, held in the present and three preceding years:—

- 1877. Book-keeping.
- " Political Economy, with the Third Prize.
- " English, with the First Prize.
- 1878. Clothing.
- " Health.
- " Cookery.
- " Housekeeping, with the First Prize.
- 1879. French.
- 1880. Commercial Geography and History.
- " Arithmetic.

The Council Prize (for Female Candidates) of Ten Guineas:—To JANE LLOYD MURPHY, aged 37, of the Birkbeck Institution, no occupation stated, who has obtained the following First Class Certificates at the Society's Examinations during the specified period:—

- 1878. Clothing, with the First Prize.
- 1879. Commercial Geography and History.
- " Cookery, with the second Prize.
- 1880. Housekeeping and Thrift.

## MISCELLANEOUS.

### HOUSE-DRAINAGE TESTS.

The Sanitary Section of the Society of Arts have had before them several tests for house-drainage work proposed by specialists. The methods employed by Messrs. Eassie, Rogers Field, and Griffith are set forth in the report of the meeting of the Section, held June 14, 1880. A report from the Board of Health of Boston has since been received, which gives the following account of a mode of testing house-drains, which has been successfully carried out in that city:—

"It is generally known that leaky house-drains are commonly detected by using peppermint, though just how this is done is not so thoroughly understood. Peppermint is not indispensable. Any of the volatile essential oils will answer as well; but, from its cheapness, peppermint is usually employed. It is put up in small vials for the purpose, one vial containing sufficient to test one line of pipe. First, remove all casing there may be around the pipes throughout the building. Stuff tow, rags, or any convenient article, as closely as may be around the pipes where they pass from one storey to another, to prevent the smell from following the pipe upward. If possible station a person on every floor, furnished with chalk or red pencil, to mark the actual location of any detected smell. If the main drain (soil-pipe) extends through the roof, station the operator at that point, with vial and two pails of hot water. Everybody being in position, let the operator pour down the peppermint, and, as soon after as possible, both pails of water, taking care not to spill peppermint on his clothes or on the floor or roof. The observers on every floor should now try to detect any smell they may be able to, and mark any such places with chalk, so that they can be examined in detail at leisure. This is the entire operation. The person on the roof must on no account for at least ten minutes leave his position; for he will surely bring the smell with him to a greater or lesser extent, and leaks may not all be detected in less than that time. If the soil-pipe does not extend to the roof as it should, run the peppermint through the upper water-closet or set bowl. If there be more than one set of pipes, and the first is found leaky, they must be tested on different days, one at a time, as it is impossible to get all the smell out of a house in less time. The cost of the peppermint is two dollars per dozen vials. Length of time required to thoroughly inspect a building, from one to five hours, depending on the complexity of the pipe arrangement."

It is stated that this plan has been adopted for testing the drainage of some of the health resorts in the United States; and, in one instance, it was found that the smell of peppermint was imparted to the water drunk by the guests.

### THE SIMLA EXHIBITION.

The Thirteenth Annual Exhibition of the Simla Fine Arts Society was opened by the Viceroy, the Marquis of Ripon, on the 17th of September. For the second time, an exhibition of native and industrial art manufactures was added to the Exhibition of the Fine Arts Society. In his remarks on declaring the Exhibition open, his Excellency said that nothing was easier than to destroy, and of all things art could, perhaps, be most easily destroyed. One form of destruction in Europe was sometimes known under the name of restoration. He hoped the day was not far distant when the ancient monuments of India might be placed under such control

as would tend to preserve them intact and unmutated to future ages. There was, much in the conditions of modern life which tended somewhat to separate and keep apart the European and native in this country, somewhat more than was the case in former days. The rapidity of communication, the weekly mails, the frequent furloughs, in spite of their advantages and blessings, all tend to a certain extent in that direction, and it is, therefore, a great satisfaction to feel that there are other circumstances connected with our time which may counteract the evil, and among them we might count that greater acquaintance we have in the present day with the history, the art, the jurisprudence of the past, which ought to help us to know better, and to appreciate more highly the native civilisation of India, to feel how ignorant is the inclination to disparage it, and that it is upon the ancient foundation of that civilisation alone that we can hope to erect, firm and enduring, the superstructure of that wider and higher life which it should be the great aim of our Government to foster and advance.

### THE NATIONAL TRAINING SCHOOL FOR MUSIC.

The third Report of the Society's Committee on the National Cultivation of Music, deals with the charter for the proposed Royal College of Music so far as national cultivation of music is concerned. An article on this subject appeared in the *Times* on November 4th, which treats of the necessity for a better musical organisation in the country, and recounts the difficulties of obtaining it. The *Times* concludes as follows:—

"The practical management of the Royal College will be essentially in the hands of a Council, consisting of the president, the principal and the vice-principal, and 30 ordinary members, a considerable portion of whom, it may be assumed, will be amateurs. In this arrangement, again, a dangerous concession to our inherent hatred of centralisation may be recognised. Without wishing in the least to underrate the services of members of the Royal Family and other distinguished persons whose names will be of the greatest use in a social sense, we may point out that not much serious business can be expected from a large and miscellaneous body of gentlemen, who will meet, perhaps, two or three times in each term, and can scarcely be expected to be acquainted with the working of the institution in detail. The real power must, in the natural course of events, lie with a few professional members, who will, at the same time, be screened from all responsibility by their colleagues. Whether it is safe to place such trust even in the most trustworthy persons is a matter we need not here discuss. Certain it is that if the House of Commons is to be asked for money, it will want the responsibility of a more tangible being than an ornamental Council."

This agrees with the observations of the Musical Committee. The successful working of the Art system, instanced by numerous witnesses as worthy of imitation, is considered to show the nature of the executive management which is required for success.

### RIVER FLOODS.

The following letter from Mr. C. N. Cresswell, appeared in the *Times*, of the 16th inst:—

"Permit me, as one of the Executive Committee of the last Public Health Conference at the Society of Arts, held on the 10th of June, to remind you that the subjoined resolution in reference to 'the prevention of floods' was unanimously passed at that Conference by representative men from all parts of the kingdom:—

"This Conference is further of opinion that such re-

representative County Boards should be instituted with the least possible delay, and that the functions intrusted to them, and the powers conferred upon them, should be wide and full, and conceived in the view of enlarging, elevating, and re-invigorating the principle of local self-government in this country; and, further, it is the opinion of this Conference that such County Boards, or combinations of them, in preference to newly-constituted authorities, should be charged with the conservancy of rivers, including the prevention of floods, the storage of water, and the preservation of rivers from pollution; and, lastly, that such County Boards should also be charged with the appointment of county health superintendents in each county.'

'This resolution, if carried into effect by Parliament, offers a solution of the formidable difficulties submitted to the consideration of Mr. Dodson on Thursday last, by the Duke of Bedford and others. Moreover, it seems to be forgotten that floods no longer leave a rich deposit of clay and other detritus upon our pastures, but, in too many cases, a filthy slime, infected with the poisonous refuse of towns and manufactories along the course of our rivers. In the opinion of some practical farmers, this is one of the causes of the abnormal diseases now prevailing among our flocks and herds, more especially among store cattle. In this aspect the question becomes one of tremendous importance, as affecting the agricultural interests, and deserves the immediate attention of Parliament.'

## CORRESPONDENCE.

### PATENT LAW.

I have the pleasure to forward herewith a copy I have received for the Society of Arts, of the volume recording the proceedings of the "Congrès de la Propriété Industrielle," held at Paris in September, 1878, and which was attended by delegates from the Governments of Germany, Spain, the United States of America, Hungary, Italy, Luxembourg, Norway, Russia, Sweden, and Switzerland.

It may be convenient that I should take this opportunity of making a few observations as to resolutions arrived at by the Congress, some of which agree more or less with certain of the resolutions I had the honour of submitting, at the request of the Council of the Society.

The subjects enumerated in the programme included patents for inventions, industrial designs, trade marks, &c. The action taken in relation to each subject is so fully recorded in the accompanying volume, that it will no doubt be deemed sufficient if I confine my remarks to the particular branch to which the Society's resolutions had reference, viz., patents for inventions.

It will be recollected that Bills for the consolidation with amendments of the Patent-laws of the United Kingdom were introduced in the House of Lords by the late Lord Chancellor in 1875 and 1876, and in the House of Commons by the late Attorney-General in 1877.

Special meetings to consider the Bill of 1877 were held by the Society of Arts on the 6th and 9th of March in that year, when certain resolutions were passed, which will be found in the Society's *Journal* of March 16th, 1877. These were the resolutions the Council of the Society submitted to the Paris Congress. One of them (the second) had reference to the preliminary examinations of applications for letters patent, and was as follows, viz., "That no adverse report of an examiner, even with a right of appeal, ought to preclude an applicant from obtaining a patent at his own cost and risk. And further, that reports containing opinions of

Patent-office authorities ought not to be made public, but that opportunity should be given to the applicant of amending his specification, by inserting reference to matters discovered by the authorities, with a definite statement of what he nevertheless claims."

The subject of preliminary examination gave rise to a long and animated discussion, and was dealt with from various points of view. The advocates of such an examination pointed out the large number of supposed inventions for which patents were taken out, and which, while only delusive, and injurious to the patentees, were, they urged, often incumbrances in the path of subsequent inventors. They argued that a previous examination by capable experts would frequently prevent these patents from being granted at all. Accordingly, our own Parliamentary Committee of 1872, the Vienna Congress in 1873, and the German Reichstag in its law of 1877, had all decided in favour of an examination. On the other hand, it was forcibly urged that the power of rejecting untried inventions for supposed want of novelty, impracticability, triviality, or any similar reason, would be a most dangerous weapon to put into the hands of examiners, however honest and capable; and instances were cited of inventions which were condemned by the highest authorities, on one or other of these grounds, and which yet proved to be most valuable. The French Patent-law, like our own, does not provide for any such examination, and it seemed possible that there would be a majority of French members against a minority containing most of the foreign delegates. However, an almost unanimous vote was at last taken in favour of a proposal based on the Society of Arts' resolution already referred to, and designed to meet both sets of advocates. The resolution, as passed, may be freely translated thus:—"Patents of invention should be granted to any applicant at his own risk; nevertheless, it is desirable that the applicant should receive a previous secret opinion, notably on the question of novelty, so that he may, at his option, maintain, modify, or abandon his claim."

As bearing upon compulsory licenses, the following free translation of a resolution of the Congress may be given:—"A patent should, during the whole of its term, assure to the inventor or his representatives the exclusive right to work the invention, and not a mere right to a royalty to be paid him by third parties working the invention."

As respects compulsory working, the Congress adopted a resolution to the effect that "it is desirable to admit of forfeiture for default of working within a term to be determined, unless the patentee justify the causes of his inaction." I may perhaps say, speaking from experience, that this resolution strikes me as most objectionable.

The Congress expressed the opinion that "a special office of industrial property should be established in each country. A central dépôt of patents of invention, trade marks, and industrial designs should be annexed for the purpose of communication to the public. Independently of any other publications, the office of industrial property should cause an official sheet to be issued periodically."

As respects fees, the resolutions of the Congress may be stated thus, viz. (1) that the tax on patents should be periodical and annual; (2) that it should be progressive, commencing with a moderate initial sum; (3) that it should only be demandable in the course of the year; (4) that forfeiture by reason of default in the payment of the tax should not be pronounced, except after the expiration of a certain delay after it becomes due; (5) that even after the expiration of this delay, it should be open to the patentee to justify the reasons of his having been prevented from paying; and (6) that this forfeiture should be pronounced by the ordinary tribunals, and not by the administration.

One of the most important resolutions passed was to the effect "that the rights acquired by patents or the registration of designs and trade marks in different countries, should be independent of each other, and in no respect interdependent, as is now the case in many countries."

It would be almost impossible to exaggerate the importance of this point, especially seeing that the country heretofore regarded as possessing the most liberal Patent-law, viz., the United States of America, seems now to be straining the interdependent theory to the very utmost extent, thereby seriously hampering patentees, without, so far as I can see, any adequate gain to the public. I think it will be found the resolutions above enumerated are those which deal most nearly with the points analogous to those to which the Society of Arts' resolutions already mentioned had reference.

Before separating, the Congress appointed a permanent committee to continue the work it commenced. This committee is composed of sections, one for each of the countries represented, the French section being the executive committee. The English section consists of Admiral Selwyn (chairman), Sir W. Thomson, F.R.S., Sir Henry Bessemer, F.R.S., Mr. Gorst, Q.C., M.P., Mr. J. G. Alexander, LL.B. (hon sec.), and myself. Unfortunately, the committee recently lost a very active member in Mr. Olrick, C.E., who died in August last.

Since the Congress, the permanent committee have occupied themselves in forwarding the carrying out by the Governments of Europe of the resolutions of the Congress, and with this object the French section of the committee entered into communication with their own Government. The French Government having expressed its willingness to take the initiative in bringing about some measure of international concert, the French section prepared, and laid before it, a proposal containing those resolutions of the Congress which seemed capable of immediate realisation for an international convention for the protection of patents, trade marks, and designs; and this proposal was sent round to the different Governments by that of France, together with an invitation to concur in an international conference for the purpose of settling such a convention. Several Governments have expressed their willingness to take part in such a conference, and I understand it will shortly be held.

At the same time, the French section of the committee, desiring to complete the work of the Congress with regard to those questions which it had been unable to enter into, prepared and sent round to the different national sections *questionnaires* to elicit their opinions on these points. Two such *questionnaires*, one on patents, and the other on designs, have been sent round, and answers have been supplied by, at any rate, the greater part of the sections.

W. LLOYD WISE.

7, Whitehall-place, London, S.W.,  
October 30th, 1880.

## GENERAL NOTES.

**Fleuss's Diving Apparatus.**—Messrs. Fleuss and Duff have called attention, in a letter to the editor of the *Times*, to the successful use of Fleuss's Patent Diving Apparatus, in that part of the Severn tunnel which is now inundated:—"The diver has succeeded in getting down the shaft, some 200 ft. deep, and then going a quarter of a mile up to the head of the tunnel, in order to close up the door so that the pumps might be enabled to clear the water out. After several unsuccessful attempts with the ordinary gear, we were applied to for our apparatus, and this was tried on Thursday, and proved a complete success, the diver easily accomplishing what had become an impossibility with the ordinary means of diving, owing to the great length of air tube necessarily required."

**The Electric Light.**—Satisfactory progress is being made in London and Paris with the Jamin system of electric lighting. Mr. Bell, the representative of the company here, is employed in fitting up an extensive plant at the establishment of Messrs. Samuel Brothers, to replace the Jablochkoff lights in use there last year. The machines will be driven by a 12-horse power silent Otto gas engine, which will actuate two self-exciting Gramme machines working from four to sixteen Jamin lights each, and which will be employed to feed twenty lamps, unless the power available should be sufficient for the whole thirty-two lamps. The speed of the Gramme machines will be 1,600 revolutions per minute. During some recent experiments in Paris, a pair of Gramme machines, exciter and distributor separate, and of the type formerly known as four-light machines, were able to maintain, when driven at a speed of 2,500 revolutions per minute, sixteen Jamin lights. The machines had been slightly altered by M. Jamin, and can be driven at 3,000 revolutions per minute without appreciably heating the coil. The Royal Panorama building now being completed in Leicester-square is to be lighted with thirty Jamin lights.—*Engineering.*

## MEETINGS FOR THE ENSUING WEEK.

- MONDAY, NOV. 22ND.**—**SOCIETY OF ARTS**, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. A. H. Church, "Some Points of Contact between the Scientific and Artistic Aspects of Pottery and Porcelain." (Lecture I.)  
Institute of Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. Francis Turner, "The Law as affecting Quantity-Surveyors."  
Royal Geographical, University of London, Burlington-gardens, W., 8½ p.m. Right Hon. Sir H. Bartle E. Frere, "Temperate South Africa considered as a Route to the Central Equatorial Region."  
Medical, 11, Chandos-street, W., 8½ p.m.

## PRACTICAL EXAMINATIONS IN VOCAL AND INSTRUMENTAL MUSIC.

The next examination at the Society's house will be held during the week commencing January 10th, 1881. Particulars will be forwarded on application to the Secretary, Society of Arts, John-street, Adelphi. No names can be received after the 24th December, 1880.

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,462. Vol. XXIX.

FRIDAY, NOVEMBER 26, 1880.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## THE PHOTOPHONE.

the announcement in the last number of the *Journal*, Professor Graham Bell, who happens for a short time, in England, has agreed to read a paper on his "Photophone" before the Society, on Wednesday, 1st December, in place of Mr. H. Preece, who is unable to read his paper that day. Mr. F. J. Bramwell, F.R.S., Chairman of the Council, will preside. For the convenience of those members who wish to be present, special rules for the admission of members and their friends will be suspended. Admission will be by ticket only, and no person, whether a member or not, can be admitted without a ticket. A limited number of tickets to fill the room will be distributed to applicants, in the order in which they apply.

Each ticket will admit one person, and is transferable. Not more than a single ticket can be used by any one member. Some tickets have already been issued, but it is hoped that all those who apply in good time may be accommodated; they should, however, apply at once to the Secretary.

By order,

H. TRUEMAN WOOD, *Secretary*.

## UNION OF INSTITUTIONS.

Following Institution has been received into the Union since the last announcement:—  
Westminster School Science and Art Classes, Westminster, near Sittingbourne.

## FOREIGN AND COLONIAL SECTION.

Meeting of Committee of this Section was held on Thursday, 19th inst., at 4 p.m. Present: Mr. Rutherford Alcock, K.C.B. (in the chair), Mr. Andrew Cassels, Mr. Hyde Clarke, Mr. C. Deschamps, Mr. Trelawney Saunders, Mr. J. A. Youl, Mr. H. Trueman Wood, secretary, and Dr. Mann, secretary of the Section. The programme of papers to be read during the present year was discussed and agreed upon.

## CANTOR LECTURES.

First lecture of the first course was delivered on Friday, 22nd inst., by Prof. A. H. Church, F.R.S., on "Some Points of Contact between

the Scientific and Artistic Aspects of Pottery and Porcelain." The lecturer dealt with bricks, tiles, terra-cotta, basalt, and unglazed earthenware in general. The lectures will be printed in the *Journal* during the Christmas recess.

## BARRY'S "VICTORS OF OLYMPIA."

With the present number of the *Journal* is issued, as a supplement, an engraving of Barry's picture of the "Victors of Olympia." The engraving is intended to illustrate Mr. Comyns Carr's paper on Barry, and is reproduced from the woodcut published by the Art Union in a series of "Thirty Pictures by Deceased British Artists, engraved by W. J. Linton." The block has been kindly lent for this purpose by the Council of the Art Union. A small number have been printed on better paper, and any member who wishes for a copy to bind with the *Journal* can have one, gratis, on application, or a copy will be posted on receipt of one shilling.

## PRACTICAL EXAMINATIONS IN VOCAL AND INSTRUMENTAL MUSIC.

The next examination at the Society's house will be held during the week commencing January 10th, 1881. Particulars will be forwarded on application to the Secretary, Society of Arts, John-street, Adelphi. No names can be received after the 24th December, 1880.

## PROCEEDINGS OF THE SOCIETY.

## SECOND ORDINARY MEETING.

Wednesday, November 24th, 1880; Sir HENRY COLE, K.C.B., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Brenchley, Samuel, Hunt Bridge-house, Matlock.  
Gassiot, Charles, Elmwood-house, Upper Tooting.  
Gundry, Joseph, Pearkes, the Cottage, Bridport, Dorsetshire.  
Jaques, Leonard, J.P., Wentbridge-house, Pontefract, Yorkshire.  
Laxton, Frederick, Brighthouse, Yorkshire.  
Nix, John H., 77, Lombard-street, E.C.  
Noel, Hon. Henry, 17, Westbourne-terrace, W.  
Northampton, Marquis of, Castle Ashby, Northampton.  
Ormerod, Thomas, Woodfield, Brighthouse, Yorkshire.  
Robertson, Sir D. Brooks, C.B., Athenaeum Club, S.W.  
Robertson, J. Murray, Lower Grove-house, Rochester.  
Seymour, Major-General W. H., 'Travellers' Club, Pall-mall, S.W.  
Sheppard, Samuel Gurney, 31, Oxford-square, W.  
Simmons, Charles J., 56, Leventon-street, Leighton-road, N.W.  
Skiffe, John Slade, 32, Milner-square, N.  
Slade, Francis William, Eldon-pk., South Norwood, S.E.  
Volk, Magnus, 40, Preston-road, Brighton.

The paper read was—

## THE INFLUENCE OF BARRY UPON ENGLISH ART.

By J. Comyns Carr.

In the summer of the year 1788, a young Irish artist arrived in London, bearing a letter of introduction to James Barry. At that time Barry had accomplished the great work of his life. The pictures which hang round the walls of this room, and which are justly reckoned as the highest effort of his genius, had been completed in 1783. In the previous year he had been appointed professor of painting in the Royal Academy, and his exercise of the functions of this office had not yet led to the series of unhappy and unfortunate disputes which terminated at last in his expulsion. Barry may, therefore, be said to have been in the full enjoyment of his fame. The youth who came to seek his friendship was, on the contrary, only just entering upon his career. Martin Archer Shee was destined to rise to the highest dignity in his profession. Forty years later he became president of the Royal Academy; and the courtly manner in which he discharged the duties of his position tend, perhaps, as much as his purely artistic gifts, to the permanence of his fame. We may assume that he already possessed some of those essential qualifications for success which Barry had always lacked. Indeed, his biographer assures us that even at this early age the young man's manners were regulated by "the highest standard of social propriety which the circles of Dublin afforded," and that such was his punctilious exactness in matters pertaining to the toilette, that, in common with most of the men of fashion of his time, he passed an hour every day under the care of his hairdresser. It is impossible to conceive of a more striking contrast than is presented between this elegant youth and the morose and solitary artist; and it is easy to imagine the shock which such a polished young gentleman must have experienced on his first introduction to Barry in his poor and lonely lodging. Writing home to his brother immediately after his visit, Shee preserves for us this lively picture of the artist and his surroundings. "Conceive," he says, "a little ordinary man, not in the most graceful dishabille, a dirty shirt without any cravat, his neck open, and a tolerable length of beard, his stockings, not of the purest white in the world, hanging about his heels, sitting at a small table in the midst of this artificial confusion, etching a plate from one of his own designs." And of the apartment itself he continues in the same strain. "The floor," he tells us, "seemed never to have experienced the luxury of an application of soap and water. The centre of it was covered by a carpet, the colour of which might once have been discoverable, but, from its intimate connection with dust and dirty feet, had long since ceased to be distinguishable from the more exposed part of the flooring." "The walls," he adds, "were perfectly concealed by an innumerable quantity of little statues, busts, and old pictures, besides casts of legs, arms, skulls, bones, hands, feet, sketches, prints, drawings, palettes, pencils, colours, canvases, frames, and every other implement calculated for the use of art, disposed in all the confusion and disorder of the most negligent carelessness."

There is something eminently suggestive in the meeting of these two men: the one young and

confident, gifted with the social qualities that ensured the sympathy of the world, and attached to a branch of art which at that time offered the only safe road to wealth and fame; the other, not yet old in years, it is true, but already arrived at the limit of his hope and ambition, cursed with a nature that had left him almost without friends and wholly without patrons, disappointed in the pursuit of a kind of art that was strange to the temper of his time, yet still resolute in the labour he had undertaken, and steadfast to the last in the faith with which he had entered upon his career. Twenty years had passed since Barry himself had come, like Shee, to try his fortunes in London, and now, although he had still many years to live, his career was practically ended. In spite of the bright hopes of the lad himself, and of the friends who had recognised and encouraged his earlier efforts, that career had been a failure. I have said he was just then in the full enjoyment of his fame, but, in truth, he never really won the sympathy of his generation, and his fame brought with it but small earthly reward. In this very year he was pleading with the Duke of Richmond for a place in the Ordnance Department, in order that he might find ease and time to produce something worthy of the eighteenth century. He was straitened in circumstances, and embittered by the sense of his isolation, and the imperfect recognition of his fellows. But this was not all. If Barry had only missed the appreciation of his time, it would be indeed a pleasant task for us of a later day to review the hardships of his life, to mark the noble aim which he ever kept before him, to recall his extraordinary resolution and self-denial, and to welcome as our inheritance the great results he achieved. Unhappily, however, Barry's failure was within as well as without. The embittered circumstances of his life have for us an extra note of pain, for the reason that we cannot rate at the value he set upon them the works that he spent his strength in producing. We cannot but perceive, looking back after this lapse of time, that between the grandeur of his conceptions, and the shapes in which they were expressed, there is a gap such as he did not dream of. I do not mean to deny the admirable qualities of Barry's work, I am well aware of the difficulties under which he laboured, and I am anxious to recognise, at its full value, the extraordinary courage with which he imagined and carried to completion the most extended experiment in decorative design which has yet been produced in this country. That, without any national tradition to guide him, and without the encouragement of contemporary examples, he should have executed the vast canvases that surround us to-night, proves, I think, that Barry possessed real power as well as a noble ambition. And yet, when all has been said that justice demands, there must still remain, I think, a painful conviction of Barry's failure. We may admit that he was not rightly understood by his age, but we must also acknowledge that he did not truly understand the kind of beauty in art which he desired to express. Of the dead, we are told, we should say nothing which is not good. It is a poor saying, for the dead of all men most sternly reject insincerity of praise, and it is no injustice to Barry's memory, to distinguish truly the inherent limitation of his powers. Rather it may be said, that the sense of

school, we shall see that, although his want as was partly due to the temper of the day, the quality of his genius, yet that it is deeper and truer sense, to be ascribed to the temper of his time, and to the general condition under which painting had been practised before. Other men might have won greater success and a larger share of popular homage. But, whatever his disposition, could have done at that time, for absolute success in the art which Barry sought to inhabit; and before becomes a question of peculiar interest to consider what there was in the spirit of the age, the general condition of the art, to shut out the members of our English school from the highest ranks of imaginative design.

One of the causes of that strange isolation in which Barry led his life, we must indeed look to the facts of his character. Barry, even in his boyhood, had an inclination to separate himself from his contemporaries. Born at Cork, in the year 1741, he was destined for his father's business of a merchant; but he quickly discovered a talent for painting, and while he was still at school, he pursued upon an independent course of study, and mixed in the ordinary boyish games or amusements.

While others were at play, he would steal into his room and set to work with his pencil, or immerse himself in the reading of some book that he had borrowed or bought. He used to alarm his father by sitting up all night at his work, and when they strove to force him to rest, he would lock his door, and allow no one to enter his room, not even for the purpose of making his bed. When he was scarcely twenty, he began a picture of St. Patrick landing on the coast of Cashel, and with this first trial of length he journeyed to Dublin, where he was just in time to have the work displayed in the exhibition of the Society. Here it attracted the notice of Mr. Burke, and thus there began, in the statesman and the painter, a friendship that endured for many years, and the records

of which are preserved in the letters of the two men. "and your credit as much as any man." To preserve during all the years of their intercourse this kindliness of feeling, must often have been to Burke a matter of difficulty and trial. Not that Barry was at any time indifferent to the value of the friendship that subsisted between them, or disposed to underrate the great benefits which it had conferred upon him. But he could not, at all times, govern his temper; he was apt to let slight and trivial disagreements obscure the memory of a noble friendship, so that there came at last a time when Burke, instead of beginning his letters with the familiar words, "My dear Barry," came at last to adopt the chilling form of "presenting his compliments" to the solitary artist. But in these earlier days Burke shows no sign of sensitiveness in his own person; all his anxiety is for Barry's future, and for the evil that he will bring upon himself, unless he can learn to bear with his fellow-men, and to keep his mind in tranquility for his work. Barry had already made himself unpopular with the artists in Rome, by seeking, with too much candour, to expose the tricks and frauds of the dealers in antiquity that haunted the city. Reynolds, who took a genuine interest in the young Irishman's career, is called in to give advice. Burke adds some of his own to the same effect. The wrathful and irascible student is warned by both against being led away from his own concerns by the malice and envy of others. He is advised to let these pretty tricksters go their own way instead of quarrelling with them. "There is," says Burke, "no living in the world upon any other terms." These small incidents in Barry's sojourn at Rome would be scarcely worth quoting, save for the indication they afford us of the morbid element in his character. In a letter written during the latter part of his stay abroad, we get the first hint of that deep strain of melancholy and mistrust, which was so strangely combined with his arrogance and irritability. Speaking of his approaching return, he writes in a desponding fashion of the

enthusiasm. His whole life proved that Barry was ready and willing to make any sacrifice for his art; and there is in all the history of art no more notable instance of absolute devotion to an ideal, a devotion which, in regard to material concerns, made no claim upon the indulgence or forbearance of others. Those who came in contact with Barry, had assuredly much to bear from his perverse and ungovernable disposition; but it is at least a noble trait in his character, that he duly counted the cost of each adventure he was to make, that he did not seek to shift his burdens on to other shoulders, and that the full extent of his failure fell chiefly in hardships inflicted upon himself. At the time that he undertook the decoration of this great room he had, so his biographer tells us, but sixteen shillings in his pocket; and during the execution of these vast canvases, he was constantly compelled, after his day's work was done, to employ himself in the evenings on drawings and etchings for the publishers. Barry's arrangement with the Society, as you are doubtless aware, through the interesting account of these transactions lately issued by your Secretary, was that he should paint these pictures at his own risk, the Society only undertaking to provide the materials, and to hand over to him the receipts arising from their public exhibition. Barry never flinched from the labour; but he must, at times, have looked forward with something like dismay to his means of livelihood during the progress of the work. In such a mood it must have been that he penned a letter to Sir George Saville, one of the vice-presidents of the Society, asking that gentleman to head a subscription in order to give the painter command of a hundred pounds a year. There is no record of any practical issue to his appeal, but to me, I confess, there is a simple dignity in this letter, which aptly accords with the proved integrity of the man. "My request and wish," he says, "is that you, sir, would subscribe £20 or £10 yourself, and prevail with such of the Society as you think proper to subscribe also, to make in the whole the annual sum of £100, to be given me monthly or quarterly, as the work goes on. I shall, by that means, be enabled to give myself up entirely to it until it be finished, which, with God's blessing, will be in about two years; and then the sum of £200, which I shall have received, shall be paid back to you and to those other public-spirited gentleman who lent it to me. If the exhibition produces nothing, or that the Society should neglect to make one, you will then lose your money; but a public work will be completed, and I shall be happy; as the opportunity of throwing myself out in such a work will be, to me, a reward fully sufficient."

This frank appeal seems to me wholly worthy of the man, and of the generous spirit in which he had undertaken this great work for the Society. That he was partly impelled by personal ambition is, no doubt, true enough. What artist is there who does not feel and acknowledge the desire of fame? But he was quite as powerfully urged to the undertaking by a truly noble desire to establish in the English school a tradition of monumental design. He had been disgusted and enraged by the failure in the previous year of the scheme for the decoration of St. Paul's; and when

Reynolds and the other members of the Academy declined the invitation of the Society to decorate this room, he came forward with alacrity and took the labour altogether upon himself. It would be easy to multiply instances bearing witness to the finer side of Barry's character; but, alas! it was not always easy for those who were his contemporaries to do justice to the grandeur of his ideas. His most generous schemes, devised for the advancement of English art, were so complicated by the violence of his temper, and by an ungenerous mistrust and suspicion of his fellows, that we are not to be surprised if he sometimes, during his career, received less than his due share of praise. His quarrel with the Academy brings prominently before us both the best and worst sides of the man's nature. The employment of the professorial chair for personal attacks upon his brother Academicians must have been intolerable to them, and I can understand that they should justly decide to deprive him of his office; but I do not understand, nor do I think any just mind can now defend, the course which they took in expelling him from the society. I cannot forget, for my own part, that Barry was not merely an intemperate lecturer, but that he was, at the same time, an enlightened and persistent advocate of reform. He incurred the displeasure of the Royal Academy, not only for his personal arrogance, but because he urged upon that body such a large and liberal conception of their duty towards the public, as did then, and has ever since, met with stubborn and dogged resistance from the majority of its members. The present is not the fit time to enter upon a question of this magnitude, but so much, at least, may be said, that if the Royal Academy had followed the lines of policy which Barry laid down, it would now be occupying a very different and a more dignified place in the esteem of the nation, and of the general body of artists. We cannot conceive of such an institution as Barry contemplated ever claiming, as the Academy once claimed, to be a private society independent of national control.

When we turn from Barry's character to Barry's art, we get upon less disputable ground. I shall not attempt to-night, with any fullness of detail, either to expound the merits or to mark the defects of Barry's painting. His most important work hangs before your eyes, and I scarcely think it likely that there is in our time room for much dispute as to the intrinsic value of the result. Whatever praise may now be accorded to his talent, would go but a little way towards satisfying the claims that were at one time put forward on his behalf. His indulgent biographer contrasts his genius with that of Raphael, not altogether to Raphael's advantage; and Barry himself, I think, believed that he had established a style combining the noblest qualities of the antique with the chosen excellence of the greatest of the Italians. Looking back with that cruel clearness of vision which comes with lapse of time, we can perceive the absolute insecurity of these pretensions. We are able to recognise that such art as this, could not, in its nature, be a full or satisfying expression of the mind of its epoch. The failure, as we have already observed, was in this sense not Barry's alone; as he was among the first, so also he was in the same respect the

the movement, the passion, and the life of human life. Men who swore to such a straitened ideal were convinced against their will, to falter in devotion to nature, and to rigidly exclude all sympathies the feelings and sentiments of the age. Even a genius so true and so refined as man's could not wholly escape from the this fashion. He was so far restrained by ailing spirit, that he could only reconstruct his ideal within the limits of a domestic one. So often as he ventured into a wide world often do his works bear the impress of a learning rather than of individual power. He did not express, through classic forms, the life of the modern spirit; he had not the power which could forge the link to bind the old to the new, and if we compare his transcript of art with that which had been made by masters of the Renaissance, we shall have to that, although it bears externally the marks of fidelity to the past, it has not an equal power to attach itself to the realities of a world.

We can recognise this limitation in the noblest art of the time, how much more strongly it impresses itself upon the products of an art whose resources imperatively demand vividness of vision, and whose effects are therefore forced upon comparison with the facts of nature. The art, of all the many forms of artistic expression, can the least afford to accept a convention which seeks to exclude from its views the energy of actual life; and, in yielding to such a convention, it must inevitably take refuge in the grandeur of Barry's colossal style, or in the pretty insipidities of a Cipriani or a Canova. But this devotion to a false idea of antique grace was not merely a mark of weakness in itself; it served no less to the painters of the eighteenth century of Italy than the benefit they might have derived from the art and example of the great masters of the

class of investigation could not be expected to reach the real spirit of Italian art. It was conducted by men who were intellectually already pledged to an impoverished ideal, which a pedantic criticism had chosen to graft upon antiquity, and who, therefore, discovered that Raphael and Michael Angelo had little to teach, which could not be better acquired from the surviving records of the art of Greece and Rome. There was, indeed, one man in England, who possessed a keener insight into the great imaginative design of Florence, and better understood the uses of its example. The genius of Blake shot a momentary radiance across the dull sky, which others could not penetrate at all, and then sank downward, with no sure footing to tread the earth. He had the vision which showed him how great a thing painting had been when it stood as the mirror of men's highest imaginings, and he was quick to perceive the extent of the change that was needed before English painting could hope to undertake this difficult duty. But he must be judged as a seer rather than as an artist, for he had no strength sufficient to effect the revolution he so ardently desired, and while he failed through lack of practical power, others who were, like Barry, more perfectly equipped, failed no less from the lack of that intensity of imagination which in Blake was developed to the point of disease.

The defects that might be anticipated from this superstitious devotion to classic style, with its consequent misapprehension of the greatness of Italian design, are easily traceable in the works of Barry. We are struck at once, in looking at his pictures, with the want of individuality, not merely in the features but in the forms, with the lack of passion and character in the faces, with the absence of expressive energy in the movement of the limbs. The action is either tame or exaggerated; the figures, even where the scale is colossal, are wanting in grandeur and dignity, and, at first sight, these things are more surprising, seeing that there existed at this time another kind of art which would have led to the development of the

Barry attempted, he too would have failed in a greater or less degree, and it remains for us to consider, as one of the most interesting problems connected with art history, in what manner the gradual progress of painting in England and in Europe had led to the decay of imaginative design, and to the assured supremacy of the departments of portrait, landscape, and the realistic illustration of contemporary manners. Looking first to England, we may see that the force of the Reformation, whatever may have been the gains in a spiritual sense, had unquestionably the effect of suddenly snapping the artistic tradition. It is not to be said that, even under more fortunate conditions, our early English painters could ever, by their independent effort, have enlarged the capabilities of their art as to render it fit to compete with that of other nations, but it is nevertheless true that, up to the time of the Reformation, English painting had a real existence; and if we go back to a still earlier date, we shall discover a period when the illuminated works of English MSS. were the most perfect in Europe. If, then, the Reformation, with the Puritan movement by which it was followed, had not entirely depressed the artistic spirit, the successive revolutions of style, which were deferred till the next century, might have more rapidly completed themselves, and the English school, as we now know it, would have had an earlier birth. But, when the Reformation came, the imaginative impulse was turned into a different channel. The force of the Protestant feeling expended itself in denunciation of the ornate luxury by which the earlier ritual had been surrounded, and, in the condemnation of Romish doctrine and practice, it was inevitable that all the outward graces of life, and the arts by which they were sustained, should be temporarily discouraged. Imagination, escaping from the control of the Church, and seeking for itself a freer realm, became, by a strange irony of fate, one of the strongest elements of opposition to the art which, of all others, most imperatively needs imagination; and the artist, thus deprived of the sympathies of those who led the new movement of ideas, made scarce any effort to keep pace with the intellectual development of the time. All the strength of our Renaissance found expression in our literature, and we are left to guess who, among the earlier poets of our school, might, under different conditions of national life, have become great imaginative painters. I know not if it is only a fancy, but I have sometimes thought that in the author of the "Fairy Queen" there dwelt the soul of a painter; and in the precise and ordered pattern of his verse, so richly and so lovingly adorned with the description of all that might give delight to the eye, we have enshrined a series of visions that might, under other conditions, have found their way on to fresco or canvas. But it is only in the earlier stages of our literature that we are permitted to indulge such fancies, for soon the poet became also the dramatist; and the drama, while it is the highest expression of the literary spirit, serves also most clearly to assert the distinctions between the modes of literature and art.

Seeing, then, how completely literature had absorbed the national energies, it is not surprising to find that the after growth of art in England is due to a foreign source. In the minds

and in the homes of the cultivated classes, the taste for art survived, and we had great collectors and connoisseurs before we could boast of great artists. Even before the Reformation had left its mark upon the English spirit, Holbein had found a home at the English Court, and when the work of the Reformation was complete, or nearly complete, Rubens, and his great pupil, Vandyck, were invited to our shores. At first sight, indeed, it may seem strange that the residence among us of these great masters of the craft did not avail, at once, to establish the tradition of imaginative design, but the solution of this riddle is to be sought as well in the nature of the art of which these men were the professors, as in that determined impulse towards literature of which we have already taken account.

When Vandyck entered upon his career, painting, it must be remembered, was no longer fit to undertake the expression of the higher problems of the spirit. In the hands of Rubens himself, art had already reached and surpassed the utmost limits of artistic license. The force, no less than the failure, of his invention put an end for a while to all further study of imaginative design, and the fallacious splendour of his most ambitious achievement was more than enough to drive other artists of less gift, or of greater refinement, into a narrower realm. To realise the decadence in the spiritual elements of painting that had been effected by the time Rubens's career was complete, it is only necessary to refer to his own copy of Mantegna, in the National Gallery, and to compare it with the original cartoon at Hampton Court. As we stand before the brilliant essay of this matchless master of the brush, we have to confess to ourselves that one great epoch in ideal art was closed when gods and goddesses descended to take upon themselves the ample flesh of Flemish men and women. Rubens himself was passionately attracted by the noble inventions of the great masters of Italy, and, with his unapproachable talent, he, if any man, could have revived and sustained the tradition they had established. He had lovingly copied their paintings, and studied their drawings; he had passed from Venice to Florence, reaping, as he went, all the harvest that was still left upon the field; and yet, as often as he tries to emulate these earlier triumphs, so often does he assert, with all the frankness of his genius that their empire had ended, and that art had entered upon a new career.

It is no part of our task to-night to follow the growth, or to note the decay, of the imaginative schools of Italy; and we have no right to linger over those noble aims in painting which Giotto has furnished, and to the fulfilment of which the mighty genius of Michael Angelo was finally summoned. All that we have to observe is, the painting in the hands of such a race of gifted artists as the world never before had seen, and perhaps, never shall see again, was at last so raised in dignity and power, that the world itself and all the fortunes of humanity became reflected in the shapes of its creation. Starting with the duty of illustrating the legends of the Christian faith, these men of Florence had so deeply penetrated the secrets of nature as to be led last to recognise, with the delight of new discovery, the charm and power of the antique; as

vancing with the models of the antique them, and with the strength of their own to save them from the pedantries of mere art, they were able to create a style for us, large enough to express all the aspirations, fears, and the fate of humanity, and strong enough to keep its hold to the end upon the simplicity of nature. But, with the death of Michael Angelo, the bright day of Florentine art passed swiftly away into darkness, and we look elsewhere for the growth of those artists that still kept their vitality when they were transported into the practice of the schools of modern Europe.

For a while, and in her earlier days, ruled, with Florence, the study of spiritual art, so long as the name of Mantegna remained a power at Venice, the products of the great artists about them something of their primitive vigour.

We may recognise the influence of Michelangelo's genius while Titian was still in his early manhood, but Titian, with a career extended to the verge of a century, lived to see and partly to effect, the first changes in art that was destined to colour the art-work of succeeding generations. Of a genius too great to be content to labour in the service of an expiring master, and too youthful in spirit, even to the end of his long life, not to feel and to accept influences that were asserting themselves in his own painting, already presents to us those elements that have been found so often in the work of later schools. It was he (as his biographers have reminded us) in the catalogue of whose works there is to be found the first example of a picture that was nothing more than a study. It was he, also, who first gave dignity and lucidity to the profession of the portrait painter; and it is by no mere accident that these modern modes of art found such powerful expression at his hands. Their establishment, at least in part, signalled the exhaustion of the art upon which the earlier and more passionate schools had employed itself, and gave warning that a new art was about to make a new return to regain the freshness and the veracity of nature, and, perhaps, one day, to bring back new elements of reality, to be moulded once more to the needs and colour of our sublimest thoughts. The day has, perhaps, not yet come. From this time to our own, the claims of realism have been in the ascendant. For 300 years art has rested content with the triumph of imitation, and nearly all that has possessed a true aim has been rather artificially grafted on to its epoch, and never freely born of the

yet, in this long communion with the elements of nature, there is to be found an element for the future. For it is not to be thought that the progress of the painter's or the sculptor's craft consists of one continuous and steady development. History of the past, if we read it aright, would rather show that art is for ever passing from symbol to illusion, and back again from illusion to symbolism. The artist, in his relation to outward realities of the world, is like a man in some new and untilled tract of country, begins by making a clearing for his home, and gradually transforms what he has won, until

it bears, in every corner, the impress of his spirit and the mode of his daily life. And then, when cultivation has done its appointed task, when flowers have grown up in barren places, and patterns of his own devising have been spread over the surface of the land, the adventurous spirit, which had first led him so far from the common ways of men, once more reasserts itself. He begins to weary of the work of his hand, and grows fatigued with the order and regularity which he has so carefully implanted upon the chaos he had found. He sighs for the wilder growths that lie beyond his present domain, until, with quickened energy, and a sense almost of disgust for what he has achieved, he passes once more into the outer tangle of untamed reality, and loses himself, for a while, in the rich luxuriance of a primitive world.

And so it is with the life of art. The glory of art lies in its power to transform the common facts of nature, till they take a colour and passion from the human spirit; but, in this glory, lurk the elements of decay; for what was the living symbol in the minds of one age, becomes in the next a thing of out-worn fashion and uncertain significance. Little by little, as the dialect perfected by great men falls from common lips, it loses the accent of vitality; and, lesser scholars, trading upon their master's discoveries, are scarcely conscious how far they have changed his language, till the world finds that it is listening to a dead tongue.

When Michael Angelo died, it was vain to hope that those who came after him could carry forward the sublime style which is associated with his name, and his death, therefore, was the signal and the note of the downfall of the glorious art of Florence. But Venice had never, from the first, so closely associated itself with the higher movement of the intellect, and, therefore, the masters of Venice were able to survive the signs of intellectual decay, and were even helpful in forwarding the revolution by which it was succeeded.

We need not deny the imaginative beauty of Venetian painting in order to acknowledge that its essence lay elsewhere, and that its strength depended, not so much upon the expression of ideas, as upon a surpassing beauty in the rendering of the facts of nature. It was by the studied cultivation, from the first, of these purely naturalistic elements of painting, that the Venetian masters—Titian most of all—were enabled to herald the advent of a new style; and when art passed from Italy to Flanders, the great Flemish painters, with Rubens and Vandyck at their head, could well take from Venice something that should be of service to themselves. And it was from Flanders—as we have already hinted—that the English school borrowed its first lessons. Just as Holbein, a century before, had introduced among us the earlier and more precise style of portraiture, so Vandyck now came with the attractions of a later style, if not to found a national school of painting, at least to establish a standard of taste that should prepare the way for native painters when the time had come for them to arise.

When Vandyck died, Sir Peter Lely stepped into his place, and Lely, in his turn, was succeeded by Kneller, an artist who enjoyed the honour of having been employed at Court during the reigns of five successive sovereigns. But neither of these painters could be said to have very worthily

carried forward the principles which Vandyck had introduced, and, accordingly, when our native artists—Reynolds and Gainsborough—arose, their advent seemed like a new birth for art in England, as it certainly was a new birth for English art.

This is not the time to insist upon the beauty of the work that these men produced. All that we have to note is, that now, for the first time, England possessed a school of painting of her own, and that the departments in which that school can claim pre-eminence, are those whose supremacy Titian's genius had already forecast.

Gainsborough not only holds an equal place with Reynolds as a master of portrait, but he was, in fact, the founder of the modern school of landscape; and, when he died, Reynolds—his rival—praised him as the greatest landscape painter of his time. But it is curious to note—and that is our principal concern to-night—how these professed students of portraiture were already aware of something that lay outside the range of their work, and for the representation of which English art was not yet fairly equipped. It is almost pathetic to meet, in the writings of Reynolds, a constant reference to the masters of Italy—and especially to the style of Michael Angelo—and then to turn from his writings to his canvas, to note how little trace his ardent desire had left upon the result of his own labours. Now and again—especially in his later life—he has attempted to graft some suggestion of allegory upon the proper claims of portraiture; but, even against the will of the author, the essential attributes of his style will assert themselves, and we cannot but feel that the effort yields only a graceful fancy, that has no power of colouring the image as a whole. We find this tendency in Reynolds, because, apart from his great powers, he was an indefatigable and learned student of art. Familiar with all the victories of imagination, he sought to establish in his own country the traditions of a style that he himself could only love and admire from a distance. If we do not find the same tendency in Gainsborough, it is because he was more entirely a child of his generation, and because he accepted frankly, and without misgiving, the limitation of his age. All that Gainsborough does is done by the force of his own genius, and he had no inclination to linger over passed ideals, which lay equally beyond the range of his powers and the taste of his time. In Gainsborough's paintings we may see an exact and brilliant reflection of the resources then possessed by English art; while, in the painting of Reynolds, we may detect something more; and we are able to note the ambition, if not the ability, of the painter to enter into a wider realm. But, before either of these two portrait painters had begun their work, another artist had arisen, through whom we may say that English painting made its first effort to fit its language to the rendering of intellectual ideas. Whatever may be the faults or limitations of Hogarth's genius, his work at least possesses for us the invaluable quality of sincerity. Entirely free from affectation, and unsupported by the inherited traditions of the schools, it permits us to judge, as well in its achievement as in its failure, of the existing resources of English painting, in the first genuine essay that had been made to forge out of lines

and colours the means of intellectual expression. Reynolds, with his learning and high culture in the work of past schools, was unable, even when he attempted to touch upon imaginative themes, to conceal those defects of power which Hogarth's painting always frankly confessed. No one was ever more completely under the guidance of imaginative impulse than the author of the "Rake's Progress;" no one, on the other hand, can more justly claim the title of a born painter. But Hogarth's ideas did not rise to sublimity, and his artistic gifts were still closely confined within the scope of realistic effect. He succeeded in his fanciful compositions because he did not misunderstand or misuse the means at his command; and even in those cases where we hesitate to admit the force or the refinement of the invention, the result is still saved from insignificance by the beauty and the delicacy of the painting. He has so long been praised as a satirist, and is justly applauded for those qualities in his art that are not of the essence of art itself, that his gifts as a painter have either not been sufficiently remarked, or have been absolutely ignored. "As a painter," writes Walpole, "he had but slender merit," a judgment which later taste has partly reversed, though there still remains a vague feeling that Hogarth's work does not possess sufficient beauty to be judged by the highest standard. This feeling is, I think, partly dependent upon a confusion between the thought and the measure of its expression: it mistakes the occasional coarseness of the theme upon which he is employed for coarseness of handiwork, but although this may be true in so far as it regards the qualities of the design, where the expression must share all the defects of the thought, it is absolutely untrue as regards the qualities of his painting. As a colourist, Hogarth will bear comparison with the men of his time, and in his knowledge of tone—the law which regulates the strength of colour in position, and the modifying influence of one tint upon its neighbour—he still remains without a rival in our school.

Hogarth, Reynolds, and Gainsborough. These men are the types of what was of genuine growth in the art of their time. Their achievements were the outcome of a sure process of evolution; in their labours they had the support and guidance of a long and unbroken tradition of executive style. How instinctively, by the light of their genius, they were able to measure the resources of their command, and, with the native prudence of genius, refuse to attempt what lay beyond their powers, we have seen by reference to a different order of art, which others were vainly seeking to establish. Barry, Blake, and Haydon. Such men belong, we may say, to the church militant of art. But it is not to be said of a painter like Barry that, because he fell short of the goal toward which he pressed, that therefore his influence counts for nothing in the history of our school. The time had not yet come for such victories as he sought to win. But whoever hopes for conquest in that vast realm of ideal beauty that he saw only from afar, and with uncertain vision, must strive with something of his noble persistence and undaunted courage. He was the first notable instance in our school, of a painter devoting himself altogether to the pursuit of a kind of art that offered

hope of great immediate reward. He may, indeed, have been misled by ambition, but the ally fell chiefly on himself; and we may forget frailties of his temper—nay, we may even give the faults of his design—in gratitude for grand and austere example which he set to students of succeeding generations.

#### DISCUSSION.

The Chairman said he should be glad to say a word or two, to illustrate a few of the most important points which Mr. Carr had brought forward, before a vote of thanks to him was proposed. The comparative failure Barry had been ascribed to the temper of the times which he lived. Now, it had been his (the Chairman's) lot to see most of the European galleries, and an impression made upon him by Barry's pictures was that they were, at any rate, as good as any class of pictures of the same time to be found in any of the great European galleries. He could not call to mind in theuvre or the Luxembourg, where the French painters of a period were represented, any paintings which could be considered as good or better. He recollected some life-like pictures by David, and, without saying that Barry's were perfect, he certainly thought they were equal to anything to be found in the French school. There were none in the German school of at time so good, the Italian school was as weak as water, and the Flemish was open to the same kind of criticism. It used to be very much the fashion to deride the English school, and within his own collection the French doubted whether there was any English school at all, until 1855, when we, for the first time, sent pictures to France, and then they awakened a sort of wonder to the fact that we could show pictures like Landseer's, Mulready's, Leslie's, and here they even went so far as to say that if Mulready's paintings were put up by auction in Paris, they could fetch as high a price as any by French artists at looking at what the times were in which Barry lived, but could be expected. At that time we were plunging into the American war, how could painting be encouraged, when the people were taken up with thoughts of how they could fight with their relatives across the Atlantic? A little later, and we had the French revolution, and the political men of those days thought it wise to spend four or five millions in trying to put it down. How could you have paintings in such a time? Then came a series of Irish rebellions, and then again, with his perpetual wars, and our enormous expenditure to put him down. We had clauses in the treaty of Vienna, that no Napoleon could ever sit on the throne of France, and that he had seen the Queen of England and her Consort in Paris, embracing one of the same family, as was the custom amongst monarchs. He thought, therefore, that the art of the times was very much influenced by other things besides art. In the first place, the artist must live, and if he believed in another world, he must paint according to his ideas of that world. At the present time, domestic life in England was the dearest thing we had, and almost all our pictures were more or less illustrations of that domestic life. He maintained that our art was quite as good as French, German, or Belgian art, and a great deal better than the Italian. Mr. Carr had referred to the difficulties Barry met with in regard to painting St. Paul's; but that was not an experience peculiar to him. After the Prince of Wales recovered from his illness, and went to St. Paul's to return thanks, the members of the Society subscribed 300 or £400 to put up a memorial window. They got criticisms of the Dean and Chapter, obtained a design, and thought the window was going to be put up. Then came some curious set of arrangements for decorating the cathedral, and stopped its adoption. The design

of their window represented a miracle above, as the principal subject, and portraits of the Prince and Queen below, but the artist who was entrusted with the grand scheme said that did not suit him at all, he wanted a bigger miracle than their artist had chosen, and from that day to this they had never been able to move a step. There was a force in the Church which could not be overcome, and Barry met with the same kind of difficulty. There was one feature in Barry's paintings which struck him as throwing a light on painters' work in general, and particularly Mulready's, and that was the great earnest sincerity with which he did his best. Almost the last words he heard Mulready utter were these, "If you want to be a painter, you must not spare elbow grease, it is as hard work as anything people have to work for." Miss Amelia B. Edwards, in her admirable novel "Lord Brackenbury," expressed the same idea in these words:—"Art tolerates no divided duty. A man must give his whole soul to it—his whole time—his whole powers of observation, of memory, of comparison, of study. Even so the thing he does must always fall short of the thing he had hoped to do. The greatest painters who ever lived spent their lives, we may be certain, in the vain pursuit of an unattainable ideal. But, at all events, they did so spend their lives. They worked at least as hard as if they had been masons, or plumbers, or joiners." He thought those were words which Mr. Carr himself might have used.

Mr. Hyde Clarke said they must all desire to thank Mr. Carr for the eloquent address he had delivered, and not less to thank the Chairman for his remarks. Perhaps, at one portion of the paper, they might have had the idea that Mr. Carr was underrating Barry in relation to his circumstances and his age, but in the end they must have arrived at the conclusion that he appreciated the artist and his efforts as much as anyone. The question put was, did Barry labour in vain, and did the Society labour in vain in associating itself with Barry in these efforts. It seemed to him that Mr. Carr had, to a great extent, answered that question, and that the Chairman had fully justified the action taken by the Society 100 years ago. It was a long time to look back to, but Mr. Carr had found means to connect their interest even with that remote period. The interesting passage in which he gave the introduction of Martin Archer Shee to the author of the works around that room, brought them into connection with the men of the present day, and the reference to Sir Martin Shee seemed, to a certain extent, to answer the earlier question of the lecturer. He said there was a strange contrast between the two men, and, at that moment, he seemed to indicate a doubt whether Barry had succeeded or failed, and to suggest that he had failed, while Shee had succeeded. Those who had been in Shee's painting-room in the later years of his life, when he was painting portraits at the age of 80, could scarcely consider his career a success. He (Mr. Clarke) remembered Shee saying to him once—"You are often now brought into contact with Mr. Haydon, and he, as a matter of course, abuses the Academy. I recollect when I myself was in difficulty with the Academy. I believe Mr. Haydon's grievance against the Academy is, that on one occasion when he had sent in two pictures to the exhibition, he happened to accompany them, and he heard an Academician call over the staircase to the porter—"Whose paintings are these?" Mr. Haydon's, sir," was the reply. "Mr. Haydon's pictures to the coal-hole!" Shee added that he had a similar adventure. When he was a very young man, and painted some of those great works of genius, which young men are most capable of producing, it so happened that two works he sent to the Academy were rejected, in a year when there were a great many rejected works. The idea occurred to some one of exhibiting all those rejected works, as a challenge to the judgment of the Academy; those who got up the exhibition, sent for him

pictures, and they were to appear; but then it struck him that, after all, though he had been scandalously treated it was perhaps not wise of him, as a young man, to put himself in competition with his seniors, and therefore he sent for his pictures and got them back, not without difficulty, for they were in the catalogue. "Now," he said, "see where Mr. Haydon is, and where I am. I have no doubt if Mr. Haydon had displayed a little more tolerance, he would have been president of the Academy instead of myself." These words had a bearing on the earlier part of Mr. Carr's paper. Which was the man who succeeded—Barry or Shee? Shee enjoyed all the advantages of life; that charm of manner, which remained with him to the last, secured for him every social enjoyment, and advancement in his art to the presidency of the Academy; but he (Mr. Clarke) believed, nevertheless, that the reputation of Barry would remain when the name of Shee would only be remembered by Byron's reference to it? The real test of Barry's position was that which the Chairman had applied to it; he must be judged by the men of his day, and even by those before his day, and he would as willingly compare him with Sir James Thornhill as with any one. At any rate, with careful consideration, no one could fail to arrive at the same conclusion as the Chairman, that in relation to his own day, Barry occupied a truly great position. What did Barry realize? He succeeded no more than Haydon, and than many ambitious men, in accomplishing all the purposes of his ambition, but he did much. He prepared the way for a school of historical art in our own day. He was trammelled by the classical and academical ideas of the day, and those same notions pervaded the French school down to the last works of David. It was only broken by the force of events; although Napoleon was represented as a Roman emperor, it was necessary to present him in his grey coat; it was in reality Napoleon and Wellington who, to a great degree, overcame the tradition of art, and rendered it more natural, and in the respective countries more national. If Barry was not able to do more, they knew by the records of the Society that he was desirous of securing the natural, for there were payments made for models, and every figure was, according to his ideas, presented according to nature. Even if he somewhat failed in his high aims, they must acknowledge his sincere desire to introduce a better element into art. One feature in Barry's work was particularly deserving of notice, that was the introduction of portraits of illustrious men. If there was much absolutely classical, on the other hand how much was there national. He would conclude by moving a cordial vote of thanks to Mr. Carr for his valuable and interesting paper.

Mr. Laing was rejoiced to find that both the Chairman and Mr. Hyde Clarke had spoken in praise of Barry. For the last 50 years he had been in the habit of coming to that room, and those pictures had been lessons to him throughout his life. He was glad also to think there was a movement in the right direction in the Society, and that the cause of art had been brought forward; for he feared that, for some considerable time, they had been paying very little attention to one of the principal objects with which the Society was founded—the encouragement of fine art. He had much pleasure in seconding the vote of thanks, and bearing his humble testimony to the great painter, whose works adorned the walls of the room.

The Secretary (Mr. H. T. Wood) said it might interest the members to see an old volume which the Society possessed, and which he had on the table, containing the MS. of a great deal of Barry's correspondence on the subject of these pictures. It began with the actual letter sent by Barry to the chairman of the committee, stating who the artist was who was willing to undertake the duty of decorating the room,

when the ten artists who had been invited had declined. There were many other letters, but, perhaps, the most interesting paper in the volume was an account written by Barry himself of the circumstances which induced him to come forward, and of his object in painting these pictures. When the pictures were cleaned recently, he (Mr. Wood) had made it his business to look through all the old papers, and see if he could collect any facts not already recorded about the pictures. The minutes and other documents, however, had been so frequently gone over before with the same object, that he did not know that he was very successful in finding much that was new, but what little he did find, he put in the form of a pamphlet, which was given to all members who cared to have it. His only object in alluding to it was to say that, coming with no previous knowledge to the study of Barry's history, he could not help arriving at the same conclusion to which Mr. Carr, with his ample knowledge, had been led, as to the extreme sadness of Barry's story. In that room, where they were surrounded by his great masterpieces, where he spent so many hours of hard work, the room to which men brought his dead body that they might pay it some of that tribute of respect which they almost grudged the artist while living, it seemed a pity that they could not awaken more enthusiasm for the artist who was full of such noble aspirations. One could only look back and regret that the fulfilment was not equal to those aspirations. Still the Society of Arts might take some credit to itself for having faithfully discharged the trust left to it by Barry, and for having done what it could for his memory. Even if he had painted the pictures in St. Paul's, which he was so anxious to do, it was doubtful if his fame would have been higher than it was to-day. The Society had always cherished his pictures, and taken such care as it could of them, and now the present Council had undertaken the restoration, the result of which was before them. He would like to add that their Chairman of the evening, Sir Henry Cole, had been a member of the committee appointed to superintend the cleaning, and it was in no small degree to his careful personal attention that so successful a result had been attained.

The Chairman, in putting the resolution, said he had no doubt that owing to this lecture, Barry would be better known than he had ever been before, and that they should not again hear, for many years, the speech made, when some one said he was going to the Adelphi to see Barry—"Barry built the Houses of Parliament and not the Adelphi." That Society gave prizes and medals for the encouragement of art before the foundation of the Royal Academy, and he could not help thinking that if even the Royal Academy had a series of pictures as good of their kind, or if they could, within a reasonable time, produce a monument of the art of the present day to equal what Barry did in his day they would have reason to be thankful.

The motion having been carried unanimously,

Mr. Comyns Carr, in response, said he would not detain the meeting, except to say that he did not wish it to be thought that he differed at all in his appreciation of Barry, or of the efforts he made, from the speakers who followed him. He cordially agreed with nearly everything that had been said by those who had, perhaps, spoken more effectively in praise of Barry than he had done. He cordially agreed with the Chairman that his achievements were very great in relation to the art of his time. He had no tendency to underrate the value of our English school; he had tried to point out that at the time when Barry was working there were magnificent achievements produced in that school, and if it was no Barry who produced them, it was because an indomitable current of ideas set in another direction, and because Barry, with heroic effort, was fighting against the stream.

## MISCELLANEOUS.

## MILITARY DRILL.

EXTRACTS FROM THE REPORTS OF HER MAJESTY'S INSPECTORS OF SCHOOLS FOR THE YEAR 1879, SHOWING THE PROGRESS MADE IN INSTRUCTION IN MILITARY DRILL.

"It is to be regretted that military drill is not more frequently taught. Except in towns, there is, I know, some difficulty in the matter, but the managers of schools within a certain area might combine to obtain the services of an army instructor. Many teachers too, who have been volunteers, might, with a little trouble, secure the requisite certificate."—Mr. BERNAYS, Inspector, Durham district, p. 227.

"Military drill is encouraged in a few schools only. Its effect on discipline is always most beneficial, and I could wish to see it more general. It must, however, be smart and good. Slovenly drill is worse than none."—Mr. COLVILL, Inspector, Shrewsbury District, p. 240.

"In several schools military drill is taught, and very well taught; it is desirable that it should more often appear in school time-tables. Exercises smartly performed in the playground, generally betoken good order and prompt obedience in the school-room, and they improve the health and carriage of boys and girls."—Mr. DARTY, Inspector, Ipswich and Edmonton Districts, p. 270.

"I notice that big boys and girls are often taught exercises suitable only to infants, and that there appears to be a great dearth of originality in the exercises given to infants. Military drill and extension motions are given with great precision in some of the large voluntary schools in the metropolitan district (Stratford, West Ham, and neighbourhood), and in one or two schools the girls acquitted themselves very creditably in the extension motions."—Mr. HELPS, Inspector, Chelmsford District, p. 301.

"Drill continues to be well taught in all the schools of the Bristol Board, and in a few others."—Mr. MACKENZIE, Inspector, Bristol District, p. 338.

"Military drill is now taught in all the Hull Board schools, securing at once good physical training and an excellent help to school discipline. In voluntary schools its value is not, I regret to say, adequately recognised."—Mr. STEVENS, Inspector, Hull District, p. 388.

"The number of schools where military drill is taught continues to increase. I am sorry to say there are very few schools where sufficient attention is paid to 'position drill' in giving a writing lesson."—Mr. CAPPEL, Inspector, Warwick and Coventry Districts, p. 235.

## LONDON WATER SUPPLY.

The evidence taken by the Special Committee of the Society of Arts on the means of protecting the metropolis against conflagration, in 1874, as to the economies derivable from the consolidation of the water companies, entirely bore out the conclusions taken as a basis by Mr. Edmund Smith, and was subsequently referred to in the discussions before the Parliamentary Committees on London Water Supply. In the last report of Lieutenant-Colonel Frank Bolton, the water examiner, which has just been issued by the Local Government Board, later corroborative evidence as to

economies consequent on consolidation is brought forward. Colonel Bolton summarises these advantages under the following six headings:—

1. Unification of the metropolitan water supply will ensure a better supply of water, both as to quantity and quality, on more economical terms, and, consequently, at cheaper rates, than can be afforded by several independent companies.

2. It will ensure the introduction of constant service at an earlier date, and at a cheaper cost of alteration and adaption of fittings.

3. It will effect a saving immediately of about half a million sterling, by rendering new works proposed to be carried out unnecessary, and will utilise, for districts requiring extensions, the spare power now existing in other districts.

4. By the re-distribution of several districts into zones of levels, not only will the supply be better regulated, and waste prevented and controlled, but a great saving will be effected in pumping and other distributory expenses, in addition to the economy secured by consolidation of administration.

5. It will enable the metropolis generally, and the heart of London in particular, to be better protected from the effects of fire, by the provision of an ample and an immediate supply of water under pressure, besides the facilities for the concentration of the greatest available pressure on the most valuable and exposed positions.

6. Greater facilities will be afforded to the local authorities in carrying out these sanitary arrangements in their respective districts, which are dependent upon an ample and efficient water supply.

## INTERNATIONAL INDUSTRIAL CONGRESS, BRUSSELS.

The Congress of Commerce and Industry was held at the Brussels Bourse, in connection with the International Exhibition. Among the various Governments, that of England was officially represented by Mr. Charles Kennedy, of the Foreign Office, and Mr. John Corbett, M.P. The Congress was divided into four sections:—1, Political Economy; 2, Commercial Law; 3, Industrial Art; and 4, Applied Science, each of which elected its own officers.

The section of Industrial Art was presided over by M. Charles Bula, *chevalier* of public instruction for the City of Brussels, Mr. David Sandeman, of Glasgow, being appointed one of the vice-presidents. The President gave an abstract of a report which he had drawn up at the request of the organising committee of the Industrial Exhibition of Brussels, in 1874, and in which was developed a programme for the founding of a museum of decorative art.

## ART LIBRARIES.

This question was introduced by a report furnished by M. Havard, in which he classed these libraries as next in importance to lectures and museums.

M. Platteau said that the library of industrial art attached to the Musée Royal, Brussels, was well attended by workmen, who derived great benefit from it.

The members generally agreed in the advisability of forming a typical library, with as many subsidising libraries as possible, which should generalise art culture.

## SCHOOLS OF APPRENTICESHIP.

M. Platteau, Secretary of the Syndicate of Painting, Brussels, spoke in reference to his paper on schools of apprenticeship, in which he states that the question of teaching the various trades imposed itself on all interested in the progress of industry and industrial art. He insisted chiefly on the necessity of founding schools as complements to the workshop, and of choosing the professors from among practical manufacturers.

**M. Fourcault** observed that industrial instruction, complete and methodical, was now as necessary as literary instruction. Apprenticeship in the workshop was too long, and schools were required to shorten it. He divided industrial instruction into four degrees, according as it was destined for workmen, foremen, or manufacturers. Then he referred to the necessity of popularising instruction in drawing among workmen, who, for the most part, did not understand a plan or a sketch. Those countries which paid most attention to popularising art applied to industry would take the lead.

**Signor Vimercati** explained that there existed at Florence a school of industrial art, which was not an annexe of the workshop, but masters were requested to oblige their workmen to follow the instruction. This school gave excellent results, as also did those founded by the Roman Railway Company for the study of mechanics.

**M. Creste Lattès**, the Italian delegate, said that, in Italy, the Government undertook to bear two-fifths of the total expense of formation, by the municipalities or the chambers of commerce, of all schools of industrial art, the regulations of which it could adopt. The remaining three-fifths were subscribed by the municipalities and chambers of commerce.

**Mr. Fison**, of Bradford, described the course of instruction at the Kent College, and the Bradford dyeing school, which latter possessed a museum and a library. He considered that the schools could never be a substitute for the workshop.

**Mr. Sandeman** traced the creation of technical school in Glasgow, which originated in a meeting held in 1874. A school of weaving was first formed, then one of dyeing. He preferred the school to the workshop, where it was generally supposed that a lad was at once initiated into the difficulties of the trade, whereas really he spent several years in manual work entirely unconnected with it.

**M. Platteau**, limiting his observations to the decorative arts, would ask the establishment of technical schools of private initiative, the instructors to be chosen among specialists, supplemented by the most skilful workmen.

**Herr Steinaecker** informed the meeting that in Hungary there was very little industrial life; and the Government, in default of private initiative, had been obliged to found and subsidise the schools.

**M. O. Lattès**, in response to an invitation from the President, gave some details of technical instruction in Italy. It dated from only a few years back; but an excellent measure of the Government had, in a very short time, tripled the number of these useful institutions. Private initiative furnished at least three-fifths of the expenses of erection, the rest being contributed by the Government, who reserved the right of inspection. The workshop school was not favourably regarded in Italy.

**M. Schoy**, of Antwerp, asserted that the superiority of Paris was chiefly due to the studious character and "ferreting-out" spirit of her industrial artists. The specialist Parisian workman knew the different styles, and frequented the libraries and museums. If the artistic value of English and German manufactures had increased, this was due to the various special publications which had popularised good designs.

**M. Limousin**, of Bordeaux, was of opinion that the Government should intervene in the foundation of technical schools. England could afford, up to a certain point, to dispense with Government aid, because of her exceptional resources from endowments. He considered the present subdivision of trades a matter for regret, but it would increase with improvements in plant. The workman of the future will not produce, but will tend the machine that works, while apprentice-

ship will be reduced to the minimum of time. This would permit the workman to change with greater ease both master and trade, which might, in some cases, be very advantageous.

The following proposition was then carried unanimously:—"The Congress expresses the hope that the Government will acknowledge that industrial professional instruction and apprenticeship are of social utility; that, in consequence, they continue to subsidise and encourage the present means of instruction, and provide for this instruction in districts where private initiative has not occupied the ground."

#### CHEAP CARRIAGE OF HEAVY SUBSTANCES.

This was the first question dealt with by the Scientific Section, under the presidency of **M. Gobert**, Inspector-General, and formed the subject of three papers. The first, by **M. Louis Alvin**, government mining engineer, attached to the Ministry of Public Works, described several lines of local interest constructed in Belgium with a gauge other than the ordinary narrow gauge. **M. J. Moreau's** paper dealt chiefly with the economic side of the question, and advocated the construction, not merely of agricultural, but of rural lines, wherever there are small industries, such as stone quarries, which might be extended by their means. The paper of **M. Heinerscheid** dealt with the transport of heavy goods by rivers or canals, which, he contended, should be so far improved as to render them capable of performing the services that might naturally be expected from them.

**M. Finet** deprecated the filling up of the canals, and advocated better organisation, so that they might compete with, or at any rate supplement, the railways.

#### TELEPHONIC COMMUNICATION.

This was the subject of a paper by **M. E. Bède**, formerly professor at the Liège University, in which he traced the history of the telephone, and advocated the formation of companies for undertaking telephonic communication in each town. He recommended the use of phosphor bronze for wires instead of iron, phosphor bronze having four times the conductivity of iron, and being from three to four times as strong as steel. Aerial lines had the advantage of being easily inspected, but the disadvantage of being liable to accident, while underground lines were almost free from accident but difficult of inspection. That inventor would render great service to telephonic communication who should devise a cheap method of constructing underground lines, that should at the same time permit of easy and complete inspection.

**M. De Locht** considered that the contract should be let by public tender to one company only, on condition that the service should be open to all on paying a fee, as in the case of telegraphs.

**M. Evrard** thought the monopoly should be in the hands of the State, which would extend the system to out-of-the-way corners that offered no inducement to private enterprise.

**M. Desguin** thought only one company should work a district, otherwise the subscribers of one company would be isolated from those of another. The stimulus of competition between rival companies would be replaced by the interest the company had in increasing the number of its subscribers by perfecting its appliances and improving its service. He was of opinion that eventually all countries would be covered with a vast telegraphic system worked by their Governments; and to attain this result, the State should, for the present, leave each district free to make its own arrangement for telegraphic communication, and establish general telegraphic lines, which might be connected with the district lines, thus preparing the way for a purchase by the Government of the whole system, when the economical conditions of working shall be ascertained.

the discussion was closed by the following resolution affecting Belgium:—"The Congress, being of opinion that telephonic communications are of general use, would be glad to see some decision arrived at regard to the granting of concessions."

#### THE TRANSMISSION OF MOTIVE POWER

introduced by a paper contributed by M. Paul vauz, engineer to the Musée Royal de l'Industrie, Professor of Physics at the Brussels Technical School, M. H. Evrard, engineer to the Administration of the State Telegraphs. The authors state that it has been generally admitted that electricity could only be used to advantage in controlling, liberating, or directing other forces; but, since the invention of the electro and dynamo-electrical machines, and the progress made in their construction for electrical illumination, the problem of utilising electricity as motive power had re-appeared under a new form. It was sought to utilise the chemical energy of the fuel, so as to transform it into mechanical power, and efforts were made to transport an existing motive force from one spot to another, by means of electricity. In the same way, large steam-engines, much more economical than those of small size, their power might be distributed to the small industrial towns at a low rate, by establishing a central station for electricity, and a suitable system of conductors. The use of electricity for the transport of motive power presented the following advantages:—The reaction is easy; the conductors may follow very irregular curves, requiring less care than pipes transmitting compressed gases, steam or water; there is no risk of explosion, and the air is all the purer for breathing. The authors conclude that electricity will be the basis of the utilisation, at no very distant date, of all natural forces, hitherto wasted, such as tides and winds.

#### ELECTRIC ILLUMINATION

was the subject of a paper by M. Hector De Backer, of the Société des Ingénieurs, Government Mining Engineers, which they start with the proposition that a better method of lighting tends to equalise the conditions of living by day and night, and increase the hours of labour, thus extending production. The principal qualities which electrical machinery should possess, were:—a high yield of electric force with reference to the motive power, regularity of action, small size, low price, and easy and economical maintenance. On the sensitiveness of electric light appliances depended the quality of the light, the generating machine influencing only the quantity of production. Generally, the economical problem might be thus stated; for a cost equal to that of the light previously employed, what is the maximum of light supplied by electricity? The limit is determined by circumstances and appliances, which must be adapted to each individual case. The method now most generally adopted for diffusion was to use a globe, transparent on its underside and the rest translucent, the rays from which were reflected. The difficulty arising from electrical machines would be to make their construction improved; but that arising from want of homogeneity in the carbons could be entirely prevented. The lamp should not only be perfect itself, but also serve as a compensator to the irregularities. After describing the various lamps, incandescent, and regulators, the authors state that, if the carbons were homogeneous, the greatest perfection could be attained by the presence in the circuit, before the lamp, of an independent regulator, which should always allow the same quantity of electricity to reach the lamp, or the presence of an appliance for abstracting the surplus, if the light were regulated for a minimum of electricity. As to colour, the electric light emitted a certain amount of violet rays, which were found to exert an excellent physiological action, though

their influence on the sight was not yet determined. The white colour was perplexing rather than disagreeable; and, for the present, until the eye became accustomed to it, yellow substances might be introduced for absorbing the violet rays. The electric light left the most delicate shades of the same appearance that they have by daylight, it illuminated without heating, and also left almost all the oxygen in the air for respiration.

#### INTERNATIONAL LEGISLATION AS TO WORK.

Dr. De Paeppe addressed to the Scientific Section a letter, which was ordered to be recorded on the minutes, stating that all academies of medicine, and hygienic societies were unanimous in denouncing, as injurious to public health, and the development of the industrial capacity of operatives, the too early work of children, the absence of a thorough apprenticeship, the exercise of certain trades by women, a too prolonged or intense labour by men, the use of poisonous or injurious substances, inefficiency of ventilation, &c. Certain countries had reformed some of these abuses, but not all; and other countries did not adopt stringent regulations for fear that they should be beaten in competition by those not subject to the same restrictions. He begged that a proposal to take these subjects into serious consideration, with a view to bring about uniform international legislation, such as that which regulates the post, quarantine and maritime navigation, be placed upon the order of the day of the next Industrial Congress.

The Congress terminated by a series of excursions to the principal centres of industry in Belgium, including Antwerp, with its new harbour works, Liège and the Cockerill Ironworks, the Vieille Montagne Zinc Works, the Val St. Lambert Glass Manufactory, Verviers with its cloth works, and the new dam at Gileppe for the waterworks, Ghent, Bruges, and Ostend.

#### CITY TECHNICAL INSTITUTE.

The first report of the City and Guilds of London Institute since its registration has just been issued. It is in the form of a report by the council of the institute presented to the governors, and adopted by them at the meeting held on the 8th of November. The meeting was held in accordance with one of the regulations of the institute, which required that there shall be a formal meeting of the governors within four months of the date of registration. The institute having been registered on the 9th July, this period expired on the 9th of this month. The report states that the institute has agreed with the Commissioners of the 1851 Exhibition for a site for their future central institution. The Commissioners have granted to the institute a lease for 999 years, at a nominal ground-rent, of a plot of land about 300 ft. long by 110 ft. deep, in Exhibition-road, between the temporary French and Belgian courts, and close to the South Kensington Museum. Mr. Rutherford Waterhouse has been selected as architect, and has been instructed to prepare plans. The report then goes on to refer to the other action of the institute, the details of most of which have appeared in previous reports and in the newspapers. The institute is assisting University College, King's College, the School of Art Wood-carving, the Mining Association of Devon and Cornwall, the Nottingham Institute, Artisans' Institute, the Union of Lancashire and Cheshire Institutes, and the Horological Institute. Some progress has been made towards the erection of a technical college in Finsbury, the council of the institute having agreed with the Cowper-street Schools for the lease of a plot of ground on which the college will be built. The report also gives an account of the progress which has been made in the technical science classes held at the Cowper-street Schools, and in the School of Technical Art, South London.

# STATE INSTRUCTION IN DRAWING IN FRANCE.

The report of the Commission upon the instruction in drawing in the French "lycées" and colleges, dated June, 1880, has been lately printed and circulated. It is addressed to the Chamber of Deputies, with whom rests the adoption of the reforms proposed. M. Dolaborda is the "Président Rapporteur" of the Commission. The system of instruction, which is recommended for adoption in France, is based upon convictions very similar to those which carried the reform in England, of the schools of design, in 1852. Upon the occasion of the opening of an elementary drawing school, at Westminster, in June, 1852, the Right Hon. James Huxley then presiding, Mr (now Sir) Henry Cole delivered an address, in which he showed how the schools of design, instead of teaching the principles and practice of applied art, had been compelled, after 14 years' existence, to virtually commence their careers again, in the character of "mere drawing schools." It had taken the long period of 14 years to arrive at the conviction that, in order to educate a competent designer, the obligation could not be avoided of teaching the very elements of the art—a power of drawing. Under the inspiration of this experience, an official syllabus of instruction in drawing, issued by the Department of Practical Art, then located in Marlborough-house, was prepared by Mr Redgrave, R.A. Elementary drawing was prescribed to be the imitation of right lines, then of curves, then of copies of leaf forms, the whole forming a first course of what was styled geometrical freehand imitation. As a completion of this first course, the student had to learn some elementary geometrical drawing. He was then deemed sufficiently prepared to enter upon a course of drawing from solid examples of simple form, and to complete his knowledge in this section, he was expected to acquire the rudiments of linear perspective. This initiatory instruction in drawing has, since 1852, remained in force throughout the numerous schools of art and art classes throughout the United Kingdom, which are recipients of Government grants for drawing from the Science and Art Department. Bearing these few facts in mind, the agreement of opinion established between English reformers of a State system of drawing thirty years ago and French reformers at the present time, gives increased interest to the report of the French Commission, which runs as follows:—

"GENTLEMEN,—The problem which is now submitted to you has, in the course of late years, received close attention, and was nearly solved by the members of the 'Conseil Supérieur des Beaux Arts' as well as by those who formed the 'Conseil Supérieur de l'Instruction Publique.' After interchanging observations and discussing various projects, after labours of successive Commissions composed of both 'Conseils,' an agreement was arrived at upon modifications to be applied to the system of drawing in force in the establishments of the universities, and upon the compilation of syllabuses, according to which the re-organisation of this system should be carried out.

"In order to give early satisfaction to wishes which had been expressed, as well as to ascertain the precise scope of the action to be taken, the predecessor of the Minister of Public Instruction appointed a certain number of inspectors of drawing, whom he charged to proceed with an inquiry upon the present state of affairs in the 'lycées' and colleges, and upon the wants for which fresh measures might be found necessary. All the reports containing the results of this inquiry, undertaken during the first six months of 1879, pointed to the urgency of important reforms. They confirmed what had been previously indicated as being vices or insufficiencies of organization, and demonstrated

the reasonableness of appeals which, from time to time, had been urged for administrative solicitude.

"The Minister of Public Instruction and Fine Arts at once took notice of the reports addressed to him by the inspectors. By a decree, dated 9th July, 1879, the Minister directed a Special Commission to prepare, for submission to the Conseil Supérieur de l'Instruction Publique, a project for organizing the instruction in drawing in the 'lycées' and colleges, and by the 6th August, 1879, this Commission accomplished its task. The programme, or syllabuses of instruction prepared by a sub-Commission, especially nominated for the purpose, were approved, on that date, by the entire Commission itself.

"It is these programmes, or syllabuses of instruction that the Commission, to which I have the honour of being the reporter, has been charged to examine. I generally adopting them in principle, the Commission which embodied them has not felt itself bound to adhere strictly to the text, or to accept all the proposed details. As the Commission, which had in truth initiated the projected reform, it naturally approved, and recommended the 'Conseil Supérieur' to do so as well, a method of instruction which, contrary to usage of long standing, should be based upon giving precedence, so to speak, to the training of the eye before that of the hand, a method by which young people would be induced to consider primarily the essential meaning of the forms; and thus, it was decided that pupils should commence their instruction with linear or geometrical drawing. However predominant such method should be during the three first years of instruction, the Commission had no intention of circumscribing the practice of young drawers to the mere tracing of lines, or of estimating the value of their relations one with another. Your Commission was of opinion that, during the first three years' course of instruction opportunities should be afforded the pupils of practical applying the principles they learnt, and that elementary lessons upon drawing or ornament, the representation of objects according to their appearance, could be usefully given. In this way, whilst deriving real profit the pupils would be interested in their work, in a way that prolonged exercises in simple drawing of lines could not be expected to affect. Instruction in drawing them, the 9th, 8th, and 7th classes, would have characteristic of, and should be confined to, the limits we have just indicated; that is to say, the aim of it should be imitation and logical appreciation of right lines, a little later of curves, and later still, the representation of objects involving the simplest geometrical drawing and the elements of perspective.

"Work of a slightly advanced sort would be required of students in the sixth class. Not only would we have to practice themselves in geometrical and in shaded perspective drawing, of geometrical solids, and of a few common objects, but they would be required to make drawings from ornament in relief, taken from conventional and non-natural objects, such as moulding classic honey suckles, dentated ornaments, &c., or from bas reliefs, inspired by examples of living form such as leaves, ornamental flowers, &c., but here again imitation should be fixed, and attempts prevented to imitate either in or out of classes, any kind of drawing of a human figure.

"Students should not commence this work until they reach the fifth class, and herein lies an innovation principle which is submitted to you. This innovation gentlemen, the majority of your Commission does not any longer hesitate to propose; but I am desired to state that in the former Council, and in many Commissions preceding the present, a minority, often, it is true of very small numbers, was opposed to the principle which the majority of your Commission has seen fit to adopt.

"To justify objections against any system of instruction in geometric drawing, the authority, be

of traditional practice of masters of all epochs, as well as of certain precepts, was quoted; against which, nevertheless, it would be easy to adduce other authorities in an opposite sense. Amongst any who had facility in handling the pencil, the necessity was pleaded of developing, from early infancy, the sentiment of the beautiful, of taste, of æsthetic appreciation of form. Now the human figure, such as we see it represented in monuments of antique statuary, and in the works of the masters, being an expression of superior beauty, it was held that the best thing to be done was to bring under the eyes of pupils from the very first day, to the exclusion of all else, models, engravings, photographs, or casts, taken from antique sculptures, or the *chef-d'œuvre* of painters of the Renaissance.

"The holders of a contrary opinion—that is to say, without exception all those of the Commission or above-mentioned 'conseils,' who follow the profession of artist—insisted upon the absolute necessity of there being a primary or grammatical course of teaching drawing. 'Since drawing serves as a mode of expression, in the Fine Arts,' said M. Guillaumie, one of the most distinguished members, 'one concludes that art is its unique object, and that it is art which should be aimed at before all other instruction. Nevertheless, one finds that its useful, practical side, the means of precision which it obtains from science, and which serve as indispensable supports, even to the artist himself, are disclaimed. Before knowing how to draw a line and to recognise in it exactly its value, an affectation for ideal beauty is pretentiously set up. Is there not danger in thus appealing to the creative faculty and independence of sentiment when it would be wiser to attend to the ordering and discipline of the rational faculties? As little as a child may do in a course of instruction in drawing, it would be well for him to imbibe some sure notions, precise and practical, which may serve him during his entire life.'

"Your Commission, gentlemen, in preparing the syllabuses which are herewith submitted to you, has been animated by sentiments like those above expressed; it has had in view the progress of national intelligence.

"Instead of efforts, premature, and necessarily futile, in the presence of objects beyond their comprehension and age, the Commission proposes that beginners should work out very simple exercises, such as almost constitute an elementary mathematical apprenticeship. Instead of a system of instruction subordinated to the preferences or personal conveniences of professors, the Commission asks you to sanction, for general instruction, the establishment of a fixed doctrine, of a curriculum of progressive and scholastic study of drawing. It asks you to disengage the study of drawing from useless difficulties in which it has become environed, and to formalise and renovate its conditions; in a word, to substitute rational and thorough investigation for routine habits, or mere facility of the hand.

"Is it necessary to dwell upon abuses which, in many classes of drawing, have obtained a kind of legal force? It seems that students have too frequently been subjected to trials of patience in a specious mastery over the mysteries of hatching, stamping, or stippling. Here, imbued in the victims of this sad method, is to be found the origin of that disgust, or, at least, weariness of work, which has gone on developing during successive years of study. Something worse than ignorance has arisen, false judgment and complete incapacity, even amongst such as may be naturally endowed to conceive and represent the truth, are the outcomes of this vicious method. Let the most distinguished student in drawing, in his 'lycée' or college, be asked to copy no example dedicated to the glory of *crayon manie*, but a real, solid, object, and unless he be permitted to resort to the mendacious eloquence and babble of the style of drawing he has studied, he must find himself totally unprepared to do as he is told.

"To suppress such artificial customs, to rid, as far as possible, instruction of conventionality, we propose, gentlemen, to set our faces against drawing from the human head until such a time when the pupil, by antecedent studies and acquired experience, may find himself fortified against confusion between the purely mechanical imitation of an example, and the paramount duty of finding out how to faithfully reproduce its essential characteristics.

"It is almost unnecessary to say that the study of drawing from the head having been commenced in the 5th class, that of the entire figure will follow in the more advanced classes. To drawing from the human figure, and to the study of the various parts, will be added in the 4th, 3rd, and 2nd classes, graduated studies of agricultural fragments, of decorative figures, &c. At length, besides developing and applying preceding studies in the classes of rhetoric and philosophy, the new programme proscribes that pupils in both these last-named high classes, shall practise landscape drawing from copies, and, further, if circumstances permit it, sketches from nature, trees, buildings, &c. Circumstances permitting, a few attempts might be made in the rhetorical and philosophical classes in studying the human head from life.

"The syllabus of the drawing courses in classes of special secondary instruction, has not appeared to your Commission, to demand exceptional treatment different from that laid down for classical classes of secondary instruction, excepting, in so far as appertains to work to be done by students in special classes, where, a necessary division arises between drawing done without, and that done with the aid of instruments, and in which architectural or machine drawings of an advanced style forms part of the studies.

"For all other classes, the course of study is common to both sets of pupils. Both will be required to follow the same track, will be subject to the same tests, will study from the same models and copies; photographs on account of their negative character, and being liable to be completely misunderstood by beginners, are rigorously interdicted from the category of examples. The only exception in regard to photographs will be made as respects those from pen and pencil drawings of the masters, because in them, precise lines of the master hand are reproduced, and define such methods of drawing as are not to be expected in photographs from sculptures and paintings.

"The prohibition of photographs as examples, excepting in the cases above indicated, is a step to which your Commission attaches great importance. On this point it has expressed an opinion of conformity with that of the unanimity of the majority of the preceding Commissions. As to the establishment, proposed by the more recent of these, of a course of twenty lessons for secondary special instruction, and of fifteen lessons upon the general history of art, your Commission has been forced to the conclusion that it was impracticable. It has considered on one hand that the two hours allowed in the 'lycées' and colleges for drawing could not, without difficulties, be regulated to admit of the special courses in question, and it feared on the other hand that in the majority of cases the teaching staffs might, in the absence of efficiently tested ability to impart such instruction, as that necessary in a comprehensive history of art embracing all epochs and successive phases of art in different countries, be unable to meet the requirements expected of them.

"I have attempted, gentlemen, to bring together the considerations which have influenced us in determining the choice and compilation of the various articles composing the syllabuses of instruction, upon the adoption of which you are asked to deliberate. I should only add that in deciding to recommend the adoption of a progressive course of instruction in drawing, based upon an elementary training in geometry, your Commission has, beyond such convictions as theory alone

might carry, felt the benefit and utility which arise from a regulated and practical order of stages of instruction.

"From statistics furnished by the Director of Secondary Instruction, it appears that about a third of the students in our 'lycees' are receiving special instruction, and that of the remainder, the half, at least, of the 2nd and 3rd, do not rise beyond the 4th class. 'Thus,' as the Director of Secondary Instruction says, 'the half of our students are destined for commerce, for industrial pursuits, for manufactories, either as managers or workmen. Consequently, if instruction in drawing 'the figure from copies' be made the foundation of a scheme of tuition, the half of the students would miss those preparatory courses of precise drawing which are more closely allied to different industrial careers.

"How can one escape from being struck by the gravity of such a danger? The means of avoiding it lies in the very method and projected re-organisation of the instruction in drawing which your Commission recommends you to adopt. This method entails no sort of compromise. The vocation, otherwise exceptional, of those students who may some day become artists is not endangered, since the scientific principles they will acquire the knowledge of, will be certainly called into play. The more general interests of those who in the course of their lives may be called upon to express their ideas by more adequate means than by speech or writing, will not be jeopardised, and finally, from the philosophical point of view, a more precise notion of the conditions and uses of the art of drawing will be disseminated. In a single word, instruction in drawing thus understood and followed, would have the advantage of at once imparting to pupils a logical education, and of usefully preparing the way of their future."

To this report are appended the syllabuses proposed for the various classes in the lycées and colleges, which in a measure correspond with the stages of instruction set forth in the official Art Directory of the Committee of Council on Education.

### GUM HOGG AND ITS USES.

Under the name of Gum Hogg, a substance is described in the *American Journal of Pharmacy*, of which it is stated that the botanical source is unknown. It appears to be of a similar nature to tragacanth, taking up a large proportion of water, though it is not absolutely soluble. An experiment in this direction showed that, after being in cold water for twenty-four hours, it swelled up into a soft white transparent mass, occupying the lower half of the vessel in which it was placed; when agitated, the mass showed no disposition to form a uniform mucilage, but separated into small, soft, transparent, and rather granular fragments resembling pounded ice; this subsided at the bottom of the vessel again when it was set at rest. A second portion of the gum, by prolonged boiling with water, gave the same result as obtained with cold water.

The commercial history of this gum in North America is very interesting. It appears to have been introduced into Salem, Massachusetts, about thirty years since. At that time Salem was the head-quarters of the East India trade, and this gum came with a lot of tragacanth imported to that place from Calcutta. It was supposed that it might be used in place of tragacanth, as a cheaper article, by the shoemakers. It, however, came into the hands of a noted drug gambler of the place, and was rejected by him immediately as an inferior gum. It was next shipped to Boston for sale, and after a number of ineffectual attempts to foist it on the market, it was finally put up at public auction and sold for two or three cents a pound to one of the principal booksellers. The purchaser made a number of ineffectual attempts to utilise it for different purposes,

and finally, somewhat disgusted, placed it in the hands of a Prof. Jackson, a chemist, in the neighbourhood of Boston; he made several experiments with it, and discovered its property of forming a good non-adhesive mucilage, when boiled with an alkali. It was soon after utilised for the manufacture of marbled paper, which was just then becoming known in the country. Gradually the secret became known, and as there was a slight demand for the article at different times, small lots were brought into the country. Up to the time of the experiments being made the gum had received no name, but afterwards it was known through the trade by that of gum hogg, and it is believed that the name was given by Prof. Jackson, on account of its obstinacy in resisting the different efforts for its solution, and thus behaving like a well-known animal of similar perverse and wilful habits.

Of late years, the gum has gone considerably out of use on account of the irregularity and scarcity of the supply. The process in which this gum takes a part in the manufacture of marbled paper consists of staining the paper and the edges of books in a variegated manner. The gum is first allowed to soak in cold water until swollen, and then boiled with a weak solution of pearlsh until a thick consistent mucilage is obtained, which is strained. This forms the basis or vehicle for receiving the colours and transferring them to the paper, and is placed in a shallow tank about five feet long, three feet wide, and four inches deep. This body must be removed as often as fermentation in the mucilage renders it liquid. In cold weather this is not so frequent, but in hot weather it must be replaced with fresh at least twice daily. The colours used are the ordinary paint colours ground to a cream with thin mucilage of gum arabic. The workman standing over the tank first takes a large brush with spreading bristles, and, dipping it in his colour, sprinkles it over the surface of the tank by twirling the handle between his hands. The value of the mucilage is now shown, for the colour does not either mix with it or spread over its surface, but retains the circular form the drops would assume upon first striking a plane surface. The first colour is then followed in a similar manner by a second, using a fresh brush, and thus in turn by a third, and so on, at the pleasure of the operator, each particular drop showing no disposition to mix with its fellow. The pattern thus made is mostly of round drops, but should it be desired to vary it, combs of different degrees of fineness are drawn in different directions gently over the surface, producing beautiful wavy lines and figures. The paper is now floated gently over the surface of the tank for a few seconds, where the colour is transferred from its surface to that of the paper, and, after being hung to dry, is burnished by hot steel rollers; no particular quality of paper is needed, the only requisite being it should not be too highly calendered. A smooth piece of board is now drawn over the surface of the tank, when it is ready for a fresh operation. The edges of the books are stained in a similar manner, the book being taken unbound and pressed between boards tightly together, so that none of the colour shall penetrate beyond its surface; they are afterwards, when dry, burnished by a hot iron tool by hand. The products afforded by the process are of infinite variety, and, as can be imagined, no two products are ever exactly alike, and, by varying the colours, an almost endless kaleidoscopic change can be produced.

### THE MANUFACTURE OF PORCELAIN IN KIANGSI.

The province of Kiangsi has, for some time past, been celebrated for its production of chinaware, and the trade in this article is steadily increasing. The great bulk of it is carried in native craft direct from the factories to various points in China, up and down the

River Yang-tse-Kiang, and along the coast even as far as Canton; a large quantity is shipped *via* Kiukiang for Shanghai for transshipment to northern ports, but chiefly Tientsin. The great factories for the manufacture of chinaware are at a place called Kingtê-chên, but it is a curious fact that none of the clay employed is found in that district; this is all imported from districts in the neighbourhood of Nankang-fu, Kwangsin-fu, and Jaochow-fu. The chief reason for the selection of Kingtê-chên as a site on which to erect porcelain factories so extensively, was on account of the water found there, which, because of its cleanness and clearness, and being impregnated with salts, was considered most fit to purify and refine the clay, and unite its particles. It is said that this clay is a composition, and that two or three hundred years are required to prepare it; this, however, cannot be so, as in that case, the ware would be neither so common nor so cheap. It is conveyed from the various quarries in the district by boats and small junks, and washed, in order to purge it from any different earth, then brayed to a small powder, which the workmen continue pounding for a long time. Of this powder a paste is formed, and this is kneaded and beaten in order that it may become softer, and that the water may be incorporated with it. After the clay is thoroughly moulded, it is formed by the wheel into any shape or style that the maker pleases. When the work is satisfactory, the vessel is exposed to the sun morning and evening, but removed as the day gets warmer for fear of its being warped. The various articles are thus dried by degrees, and as soon as the ground is considered fit to receive colours they are painted, and in order to give the vessels and colours a better lustre, or a highly enamelled appearance, a very fine layer of the same porcelain is made, and the whole work washed with it. This gives that particular whiteness and lustre to be seen in the very finest ware. The next process is to put the articles into a furnace, and bake them with a constant but gentle heat, which will not break them. After they have acquired the proper consistency, they are allowed to remain some time before being withdrawn, to prevent any damage by a too sudden exposure to the cool air. The value of this chinaware depends very much upon fancy; but it is generally conceded that three things combine to make any one of the articles complete, viz., the fineness and rare finish, the painting and designing of the figures, and the shape and fashion of the work. The fineness may be tested by the transparency which is discernible chiefly about the edges of the article. The whiteness is often confounded with the varnish, but it is said that age in time makes a plain distinction, for the varnish will tarnish in the long run, and the whiteness becomes more apparent. The smoothness and fineness consist in the brightness of the varnish and evenness of the work. The former must not be too thick, because in that case there will be a crush upon it, and it will shine too much, and the surface is only perfectly even when it has not the least rising or the smallest depression to be seen, although few pieces are without some of these defects. In colouring the chinaware, imperial yellow, milky white, red, and grey are the favourite grounds on which are painted figures, landscapes, flowers, trees, birds, and arabesques, though turquoise blue, pale pink, mazarine blue, and sage green grounds are often employed. Arabesques are more frequently met with than any other style of ornamentation, and they are generally in borders, but are also used for enriching the whole surface of vases, consisting of fanciful and ideal mixtures of all sorts of figures, real and imaginary, often truncated and growing out of plants; also all sorts of plants, and involved and twisted foliage. Many of the designs in painting are mean and common, flowers and trees are often fairly well done, but the figures of men are, as a rule, monstrous, whereas other pictures are bold and well proportioned. The

finest specimens are selected by an official for the Court at Peking, and these are called Imperial ware ("Kuan Yao"), and each article bears a "Kuan Yin" or furnace stamp upon the back, which merely gives the year of the dynasty reigning at the time of manufacture. All the other ware is designated "Min Yao," meaning the ware made for the people; that is of a common kind. Several samples of the Kiukiang porcelain were exhibited in the Philadelphia and Paris Exhibitions of 1876 and 1878.

## GENERAL NOTES.

**Technical Education.**—Sir John Bennet has addressed a letter to several of the morning papers, stating that he is about to bring forward a resolution at the Common Council, that a grant of ten thousand guineas be made to the City and Guilds of London Institute for the promotion of Technical Education. It will be remembered that although the Corporation has always had representatives on the governing body of this institute, they have not as yet contributed anything towards its funds.

**Cutlery Company.**—A course of lectures, on subjects connected with the materials used in the manufacture of cutlery, is arranged for delivery in the Cutlery-hall in December, 1880, and January, February, and March, 1881. The first lecture will be by Sir Henry Bessemer, "On the Manufacture and Uses of Steel, with Special Reference to its Employment for Edge Tools." A subsequent lecture will be given by Prof. Huntingdon, of King's College.

**Electric Light Wires.**—A letter from Mr. James Harrison, superintendent of the New York Board of Fire Underwriters, dated October 21, is printed in the *Scientific American*, which contains an account of an accident occasioned by electricity from an electric light wire in the office of Messrs. Silcox and Co., of New York:—"One day, either Monday or Tuesday last, some persons on the roof of one of the intervening buildings, dropped an electric light wire upon that of the telephone wire of Messrs. Silcox, bringing the two wires in contact. The effect rather astonished the people in the office. Flames burst forth from the telephone instrument on the wall, producing such an intense heat as to entirely destroy the magnets." The editor points out that such an accident as this may be prevented by covering the electric light wires or the telephone magnets with insulating material, and urges the necessity of this precaution.

**Edinburgh School of Cookery and Domestic Economy.**—The sixth session of this school, and the first under its extended name, was opened by Dr. Boddie, F.R.S., president of the Health Section of the Social Science Congress. The subjects to be taught during the session 1880-81 are:—I. Cookery (demonstration and practice). II. Ironing, clear-starching, and the French method of doing up fine lace. III. German method of cutting out dresses, &c. IV. Ambulance lectures on first aid to the injured. V. Physiology and health. A small library of the leading books on food, cookery, and physiology has been formed for the use of students. The Hon. Secretary is Miss Guthrie Wright, 6, Strandwick-place, Edinburgh.

**Porcelain Clays.**—Prof. Wurtz, who, a year or two ago, examined some of the so-called porcelain clays used at Arita, found that they were no clays at all in the scientific sense of the term, and hence drew the startling conclusion that the Japanese porcelain is not prepared from china-clay. Many other analyses, however, have been made by Prof. R. W. Atkinson, formerly of University College, London, and now of the University of Tokio. These analyses, which have lately been published by the Asiatic Society of Japan, do not, on the whole, bear out the views of Prof. Wurtz. At any rate they show that the composition of some of the clays of Japan is very similar to that of ordinary Kaolin. One of the Satsuma clays, for example, contains 61.79 per cent. of silica, 30.91 of alumina, and 11.74 of combined water. It is true, however, that some of the other analyses agree with those of Wurtz; indeed, one of them shows as much as 81.86 per cent. of silica. But, notwithstanding such analyses, it is clear that true porcelain-clay is used by some at least of the Japanese potters.—*The Academy*.

## MEETINGS OF THE SOCIETY.

## ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock. For meetings previous to Christmas:—

DECEMBER 1.—“The Photophone.” By Professor ALEXANDER GRAHAM BELL. F. J. BRAMWELL, F.R.S., Chairman of Council, will preside.

DECEMBER 8.—“London Fogs.” By Dr. ALFRED CARPENTER. EDWIN CHADWICK, C.B., Vice-President of the Society, will preside.

DECEMBER 15.—“The Use of Sound for Signals.” By E. PRICE EDWARDS, Secretary to the Deputy-Master of the Trinity-house. Dr. TYNDALL, F.R.S., will preside.

For Meetings after Christmas:—

“Buying and Selling; its Nature and its Tools.” By Prof. BOXAMY PRICE. On this evening Lord ALFRED S. CHURCHILL will preside.

“Causes of Success and Failure in Modern Gold Mining.” By A. G. LOCK.

“The Participation of Labour in the Profits of Enterprise.” By SEDLEY TAYLOR, M.A., late Fellow of Trinity College, Cambridge.

“The Gold Fields of India.” By HYDE CLARKE.

“Flashing Signals for Lighthouses,” By Sir WM. THOMSON, F.R.S.

“The Present Condition of the Art of Wood-carving in England.” By J. HUNGERFORD POLLEN.

“Five Years' Experience of the Working of the Trade Marks' Registration Acts.” By EDMUND JOHNSON.

“Trade Prospects.” By STEPHEN BOURNE.

“The Manufacture of Aërated Waters.” By T. P. BRUCE WARREN.

“The Compound Air Engine.” By Col. F. BEAUMONT, R.E.

“Improvements in the Treatment of Esparto for the Manufacture of Paper.” By WILLIAM ARNOT, F.C.S.

“Deep Sea Investigation, and the Apparatus used in it.” By J. G. BUCHANAN, F.R.S.E., F.C.S.

“The Discrimination and Artistic Use of Precious Stones.” By Prof. A. H. CHURCH, F.C.S.

“Forest Conservancy in India.” By Sir RICHARD TEMPLE, Bart., K.C.S.I.

“The Tenure and Cultivation of Land in India.” By Sir GEORGE CAMPBELL, K.C.S.I., M.P.

“Indian Agriculture.” By W. R. ROBERTSON.

“Trade Relations between Great Britain and her Dependencies.” By WM. WESTGAERTH.

“The Languages of South Africa.” By R. CUST.

“The Loo Choo Islands.” By Consul JOHN A. GUBBINS.

## CANTOR LECTURES.

Monday Evenings, at eight o'clock. The First Course, on “Some Points of Contact between the Scientific and Artistic Aspects of Pottery and Porcelain.” Five Lectures, by Prof. A. H. CHURCH, M.A. Oxon., F.C.S.

## LECTURE II.—NOVEMBER 29.

Vitreous, plumbiferous, boracic, and felspathic glazes and enamels. Iridescent and metallic lustres, and colouring substances.

## LECTURE III.—DECEMBER 6.

Stoneware and other wares glazed with salt.

## LECTURE IV.—DECEMBER 13.

Soft paste porcelains, European and Oriental.

## LECTURE V.—DECEMBER 20.

Hard paste porcelains, Chinese, Japanese, and European.

The Second Course will be on “Watchmaking,” by EDWARD RIGG, M.A. Three Lectures.

The Third Course will be on “The Scientific Principles involved in Electric Lighting,” by Prof. W. G. ADAMS, F.R.S. Four Lectures.

The Fourth Course will be on “The Art of Lacemaking,” by ALAN S. COLE. Three Lectures.

The Fifth Course will be on “Colour Blindness and its Influence upon Various Industries,” by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

## ADMISSION TO MEETINGS.

Members have the right of attending all the Society's meetings and lectures. Every Member can admit *two* friends to the Ordinary and Sectional Meetings, and *one* friend to the Cantor Lectures. Books of tickets for the purpose have been issued to the Members, but admission can also be obtained on the personal introduction of a Member.

## MEETINGS FOR THE ENSUING WEEK.

- MONDAY, NOV. 29TH. SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. A. H. Church, “Some Points of Contact between the Scientific and Artistic Aspects of Pottery and Porcelain.” (Lecture II.)  
British Architects, 9, Conduit-street, W., 8 p.m. Mr. E. C. Robins, “Sanitary Science in its Relation to Civil Architecture.”  
Institute of Actuaries, The Quadrangle, King's College, W.C., 7 p.m. Presidential Address, by Mr. A. H. Bailey.  
Medical, 11, Chandos-street, W., 8½ p.m.
- TUESDAY, NOV. 30TH. Royal, Burlington-house, W., 4 p.m. Anniversary Meeting.  
Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m. Renewed Discussion upon Mr. Maxwell's Paper, “New Zealand Government Railways,” and on Mr. Mosse's Paper, “Ceylon Government Railways.”  
Zoological, 11, Hanover-square, W., 8½ p.m.
- WEDNESDAY, DEC. 1ST. SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Prof. Alexander Graham Bell, “The Photophone.”  
Geological, Burlington-house, W., 8 p.m.  
Entomological, 11, Chandos-street, W., 7 p.m.  
Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m. 1. Mr. C. B. Allen, “Note on the History of Saffron.” 2. Mr. E. M. Holmes, “The Use of Saffron in Pharmacy.”  
Archæological Association, 32, Sackville-street, W., 8 p.m. 1. Rev. Dr. Hooppel, “The Explorations of the Roman Station of Vinorium (Winchester).” 2. Dr. Wake Smart, “Roman Remains at Nursling, Hants.”
- THURSDAY, DEC. 2ND. Antiquaries, Burlington-house, W., 8½ p.m. Linnean, Burlington-house, W., 8 p.m. 1. Mr. Frederick Townsend, “An *Erythraea* new to England.” 2. Dr. Maxwell Masters, “The Conifers of Japan.”  
Chemical, Burlington-house, W., 8 p.m. 1. Mr. W. Ramsey, “Communication from the Laboratory of the University College, Bristol.” 2. Laura Mauds Farnsvant, “The Specific Volume of Chloral.” 3. Mr. J. W. Hamilton, “The Formation of Carbon Tetrabromide in the Manufacture of Bromine.” 4. Ballot for the Election of Fellows.  
South London Photographic (at the House of the Society of Arts), 8 p.m.
- FRIDAY, DEC. 3RD. Philological, University College, W.C., 8 p.m. Geologists' Association, University College, W.C., 8 p.m. Archæological Institute, 16, New Burlington-street, W., 4 p.m.

## VAL OF THE SOCIETY OF ARTS.

No. 1,463. Vol. XXIX.

FRIDAY, DECEMBER 3, 1880.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## THE PHOTOPHONE.

ection of the diagrams used by Professor  
Bell, to illustrate his paper on the Photo-  
will be reproduced in next week's *Journal*.  
as not been sufficient time to allow of the  
being prepared for the present issue.

## CANTOR LECTURES.

second lecture of the first course was de-  
on Monday, the 29th ult., by Prof. A. H.  
, M.A., F.R.S., on "Some Points of Contact  
the Scientific and Artistic Aspects of  
and Porcelain." The lecture was devoted  
treatment of glazes, enamels, lustres,  
louring substances. The lectures will be  
in the *Journal* during the Christmas recess.

TICAL EXAMINATIONS IN VOCAL AND  
INSTRUMENTAL MUSIC.

next examination at the Society's house  
held during the week commencing January  
31. Particulars will be forwarded on appli-  
to the Secretary, Society of Arts, John-  
delphi. No names can be received after  
December, 1880.

## MEEDINGS OF THE SOCIETY.

## THIRD ORDINARY MEETING.

uesday, December 1st, 1880; F. J. BRAM-  
F.R.S., Chairman of the Council of the  
in the chair.

ollowing candidates were proposed for  
as members of the Society:—

fra, 26, St. Peter's-square, Hammersmith, W.  
mes, 9 and 10, Baker-street, Portman-sq., W.  
bomes, Church Entry, 75, Carter-lane, E.C.  
Godfrey Charles, 22, King-street, Portman-  
W.

Macauley, Lieut.-Colonel George William, 43, Craven-  
road, W.

Stubs, Peter, Statham-lodge, Warrington.

Symmons, Edmund, Eagle-house, Bermon-hill, Wood-  
ford.

Walker, Robert, J.P., Kidwells park, Maidenhead.

Waterhouse, Sebastian, 37, Catherine street, Liverpool,  
and Windham Club, S.W.

Williams, William Henry, 23, Holland-park, W.

The following candidates were balloted for, and  
duly elected members of the Society:—

Allcock, Arthur Thomas, 5, Spring-gardens, Newark-  
upon-Trent.

Atkinson, Frederick William, 137, Leadenhall-street,  
E.C.

Aylmer, Capt. John Evans-Frcke, M.P., Aylmersfield,  
Streatham.

Baillie, J. H., 15, Old Bond-street, W.

Baxter, F., South Eastern-wharf, Park-street, S.E.

Bell, R., 83, Knight-rider-street, E.C.

Bennet, Peter Duckworth, Edgbaston, Birmingham.

Biggs, Benjamin, 3, Laurence Pountney-hill, E.C.

Blackwood, Richard, 96, Cromwell-road, South Ken-  
sington, S.W.

Blamires, Thomas Howard, Close-hill, Lockwood, near  
Huddersfield.

Blyth, James, 31, Park-terrace, Regent's-park, N.W.

Capel, Frank C., The Mount, Wilmington, Kent.

Carpmael, Alfred, 1, Copthall-buildings, E.C.

Clark, William Timbrell, Kilsby, near Rugby.

Collington, James B., Beeston, Nottinghamshire.

Comerma, Capt. Andrés A., 48, Macfarlane-road,  
Shepherd's-bush, W.

Cottew, William Stokes, The Bank, Tottenham.

Cranwell, William B., 42, Portesdown-road, W.

Crookenden, Isaac Adolphus, Marlborough-house,  
Blackheath, S.E.

Deane, James Parker, D.C.L., Q.C., 3, Paper-buildings,  
Temple, E.C., and 16, Westbourne-terrace, W.

Deaville, Rev. Joseph Gibson, Agincourt-villa, Bury,  
Lancashire.

Dewrance, John, 176, Great Dover-street, S.E.

Eaton, Francis James, Albert-road, Hesketth-park,  
Southport, Lancashire.

Emptage, Daniel, Dane-hill Sanitary Works, Margate.

Estcourt, Roland M., Local Government Board, S.W.

Evans, Lieut.-Colonel John, Highfield, Derby.

Ford, George Benjamin, 196, Westminster-bridge-road,  
S.E., and 9, Cuthill-road, Denmark-hill, S.E.

Freeman, William George, 44, Kensington-square, W.

Gordon, Surgeon-General C. A., M.D., C.B., Q.H.P.,  
70, Cambridge-gardens, W.

Grant, Sir John Peter, K.C.B., G.C.M.G., The Doune  
of Rothiemurchus, Aviemore, N.B.

Greenall, Lieut.-Colonel James Fenton, Lingholme,  
Derwentwater, Cumberland.

Guest, Montague J., M.P., 3, Savile-row, W., and  
Bere Regis, Blandford, Dorset.

Guthrie, Herbert, 32, Brown-street, Manchester.

Hall, Alexander Lyons, F.R.G.S., Lyon's-court, Lad-  
broke-road, Holland-park, W.

Harper, George Thomas, Southampton.

Harvey, William Charles, 12, Old-square, Lincoln's-  
inn, W.C., and 8, Warwick-road, Maida-hill, W.

Haynes, F., Superintendent's Office, Telegraph Depart-  
ment, G.W.R., Taunton.

Heyworth, Lieut.-Colonel Lawrence, Wain Vawr,  
near Newport, Monmouth.

Hickman, Alfred, Goldthorn-hill, near Wolverhampton.

Homan, Ebenezer, Friern Watch, Finchley, N.

Hulse, Joseph, Dresden, Longton, Staffordshire.

Isaac, Benjamin, 102, Piccadilly, W.

Johnson, Walter Claude, Rivoli, Old Charlton, Kent.

Judson, Frederick Henry, 77, Southwark-street, S.E.

Keyser, Charles Edward, M.A., F.S.A., Merry-hill-  
house, Bushey, Herts

Lambe, J. B., 199, Upper Thames-street, E.C., and 427, New-cross-road, S.E.  
 Lightfoot, Thomas Bell, 2, Granville-park, Blackheath, S.E.  
 Lingard-Monk, Richard Boughey Monk, 4, Westminster-chambers, S.W., and Fulshaw-hall, Wilmslow, Cheshire.  
 Lovell, Richard J., 48, Oakley-road, Canonbury, N.  
 McDonald, James E., 4, Chapel-street, Cripplegate, E.C.  
 Marriner, William Tyler, Eton-villa, King Edward's-road, South Hackney, E.  
 Marshall, Alfred, The Villa, Muswell-hill, N.  
 Martin, John Cowdery, White Lead Works, Ossory-road, Old Kent-road, S.E.  
 Mineard, George Edward, 57, Warwick-road, South Kensington, S.W.  
 Moser, Charles E., Brooklyn, 75, Upper Tulse-hill, S.W.  
 Neal, James, 21, Lime-street, E.C.  
 Nyland, James, 42, Burlington-road, St. Stephen's-square, Bayswater, W.  
 Paddon, Samuel Wresford, Brooklyn, Chislehurst.  
 Pearson, Joseph Hickman, J.P., The Leveretts, Handsworth, near Birmingham.  
 Pfounds, Charles, F.R.G.S., M.R.S.L., 1, Cleveland-row, St. James's, S.W.  
 Pickering, Charles William Harrison, J.P., New Brighton, Cheshire.  
 Pinnock, Henry, J.P., Beechwood, Newport, Isle of Wight.  
 Pursell, John Roger, Kingston-road, Merton, Surrey.  
 Puzey, William, 5, Aldermanbury-postern, E.C.  
 Quincey, Edmund de Quincey, 76, Avenue-road, Regent's-park, N.W.  
 Ravenscroft, Sidney Horace, Powis-lodge, Haverstock-hill, N.W.  
 Robinson, John, F.G.S., Kingscote, East Grinstead.  
 Robson, John, Tynemouth-road, The Green, Tottenham.  
 Rogers, J. H., Moore-place, Esher, Surrey.  
 Rothwell, Richard, 45, Holland road, Kensington, W.  
 Rudd, William Albert, Gloucester-house School Science and Art Classes, Ddington, near Sittingbourne.  
 Simpson, George Palgrave, 2, Mount-terrace, Richmond, Surrey.  
 Sonnenhal, George, 85, Queen Victoria-street, E.C.  
 Southee, Arthur Philip, Mount Edgecumbe, Ramsgate.  
 Squire, John Barret, Worston-house, Durning-road, Liverpool.  
 Stanger, George Hurst, Queen's-chambers, North-street, Wolverhampton.  
 Stone, James Henry, J.P., Cavendish-house, Grosvenor-road, Handsworth, Birmingham.  
 Tarr, William, 83, Knight-ridge-street, E.C., and Fenn-dale, Walton-on-Thames.  
 Trench, Lieut.-Col. the Hon. William Le Poer, R.E., 3, Hyde-park-gardens, W.  
 Verity, John, 31, King-street, Covent-garden, W.C.  
 Warrick, Robert Betson, 27, Woburn-square, W.C.  
 Weager, James H., 26, Leadenhall-street, E.C., and Tottenham.  
 Weir, James, 49, Jamaica-street, Glasgow.  
 Wells, Charles A., 1, High-street, Lewes, Sussex.  
 Wing, John Unwin, Brinkburn-grange, Sheffield.  
 Wyatt, Vitruvius, Gas Light and Coke Company, Beckton, E.  
 Ziegler, David, 7, Upper Woodland-terrace, New Charlton, Kent.

The Chairman said it was the duty of a chairman, as a rule, to introduce the reader of a paper to the meeting, but this evening it was quite superfluous for him to do so. He should have to accuse the members of the Society of Arts of want of gratitude, and even of not belonging to civilised society, if he assumed that Prof. Graham Bell required any introduction, because he was prepared to say that Prof. Graham Bell, whose paper on the telephone they had listened to with so

much pleasure, two years ago, had made for himself world-wide reputation in all places claiming civilization. In that room, Professor Bell had, two years ago, brought before their notice an account of telephone, with which they were so much interested. They were all, of course, glad to find that he had rested on the reputation he then made, but that he continued the devotion of his mind in that particular direction, the result of which had been the production of this marvellous instrument, the photophone. would not waste any further time, but simply call to Prof. Graham Bell.

The lecture was on—

## THE PHOTOPHONE.

By Professor Alexander Graham Bell.

I had hoped to have been a listener here to-night instead of a speaker. While I was uncertain whether my engagements abroad would permit me to be present in England, I still intended to make an effort on this occasion to hear Mr. Preece read a paper he had promised. I am sorry that circumstances have disappointed me in hearing and speaking on this subject; but I need hardly tell how much pleasure it gives me to come before the members of the Society of Arts.

The facts of science are often more marvellous than the imaginations of fiction, and to-night have to bring before you one more illustration of the truth of this saying. That we should be able to talk along a beam of light as we do through a speaking tube, seems almost too marvellous for comprehension; but you are aware that everything is easy when you know it is done, and it will be my duty to-night to explain to you the *modus operandi* by which this wonderful result is obtained—to show you how we can produce the sounds of articulate speech at distant places by the simple agency of a quiver of light. It will be necessary, however, before entering on this subject, to say a few words of the curious discovery that was first announced to the world in February, 1873, by Willoughby Smith, who discovered that the curious element, selenium, has its electrical resistance affected by the influence of light; when light falls upon selenium a free passage is opened up among the molecules of a current of electricity, whereas, in the dark, the resistance of this substance is enormous. We know that selenium was discovered in the year 1817, by the great chemist, Berzelius, in attempting to discover tellurium in the residues obtained in the manufacture of sulphuric acid. He found that it was a non-conductor of electricity, but Hittorf discovered, in 1851, that selenium became a conductor of electricity in one of its allotropic forms. When selenium is fused, and slowly cooled from the fusing-point, it is found to be in a crystalline condition; in this condition it is a conductor of electricity at ordinary temperatures. To Mr. Willoughby Smith and to his assistant, Mr. May, is due the discovery that I here allude to, that the conductivity of selenium is affected by light, and that we have an opportunity of exhibiting this effect to you to-night, by throwing on this selenium a ray of light reflected from the mirror of a galvanometer. A piece of selenium, which is

parabolic reflector at the end of the room, is connected in the circuit with this galvanometer and a rheostat. The resistance of the selenium is balanced, so that the spot of light should not be deflected to any material extent when a current of electricity passes through the circuit; but on throwing light upon the selenium, we shall immediately obtain a marked deflection of the galvanometer; or, in other words, of the spot of light. We shall have to be very still until the spot of light comes to rest, as the slightest movement on the platform will disturb this delicate instrument—the galvanometer. I have in my hands a little mirror, by which I can throw a beam of light on the screen, and if the experiment should prove successful, we shall be able to obtain a deflection of that beam of light. I may say that this is a difficult and delicate experiment, and may not at first be successful, but I hope to obtain a deflection of that spot of light. You observe the moment the light is thrown into the parabolic reflector the resistance of the selenium is reduced, and the deflection of the galvanometer occurs. You will understand that the action of the light is to cause a diminution of the electrical resistance of the selenium, so that the resistance which was balanced while the selenium remained in the dark, was no longer balanced when the light was thrown upon the selenium.

Although, as I have said, selenium was discovered by Berzelius in the year 1817, more than half a century passed before this substance was regarded as anything more than a chemical curiosity. Mr. Willoughby Smith was the first, so far as I know, to attempt to utilise it in the arts. On account of its enormous resistance to the passage of the electric current, he thought it might be used in his system of signalling and coding during the sub-mergence of submarine cables. For this purpose, he made experiments on the Atlantic cable at Valentia, and it was during the course of these experiments that the discovery was made, that the electrical resistance of this substance was affected by light. The mode in which selenium was used consisted of a bar of selenium with platinum terminals fused into the ends for purposes of connection, and placed inside a glass tube, hermetically sealed. When experiments were made on the submarine cable, it was found that the selenium had all the resistance required. Some of the little bars, an inch or two in length, measured as much as 1,400 megohms, a resistance equivalent to that of a telegraph wire long enough to reach from the earth to the sun, but it was found to be extremely variable. In seeking for the cause of this variability, the discovery was made that the resistance varied with the amount of light falling on the selenium. It is not my object to take up your time to-night by describing the interesting researches that followed on this discovery by Mr. Willoughby Smith. You must all be familiar with the researches of Draper, Farth, Sale, Adams, Sabine, and Siemens. I shall merely direct your attention to one or two forms of selenium apparatus devised by Dr. Werner Siemens. In the first diagram, you will see what is known in America as Siemens's grating, in which the resistance is sought to be reduced by laying two platinum wires arranged in a zigzag

form. The whole is covered with selenium, and the current, in passing from one wire to another, has to pass through the selenium. On account of the length of the two wires, the resistance is very greatly reduced. The other form of apparatus is that which is popularly known as Siemens's spiral, in which these two wires, instead of being arranged in a zigzag form, are coiled together so as to form a double spiral, on which is placed a strip of melted selenium. The whole is arranged between two mica plates and pressed together, being afterwards annealed, to produce crystallisation. I am glad that we have here to-night some of the ingenious apparatus devised by Dr. Werner Siemens, and I am also glad that we have upon the platform to-night, Dr. C. W. Siemens, and I hope he will explain to you, and exhibit in operation, the ingenious "selenium eye" that we have upon the platform. In practical experiments with selenium, the enormous resistance is a difficulty; and I shall show you a few forms of selenium cells, devised by Mr. Sumner Tainter, of Washington, and myself. We have been working on this subject for many months past, and have produced selenium cells of such a low resistance, as to be of practical use in experimental work—such low resistance, that we can use them in telephones and galvanometers of ordinary construction. The resistance of selenium cells hitherto employed, have generally been measured in millions of ohms; the lowest resistance I know of has been 250,000 ohms in the dark, but in the form of selenium cells, as shown on the screen, the resistance is only 300 ohms in the dark, and 150 ohms in the light. I will briefly describe the arrangement. If you look at the illustration at the top of the screen, you will see that it represents two brass plates, separated by mica. The upper plate is perforated, and the lower plate has metallic pins attached, which pass through the upper plate, so that their tops are flush with the upper surface of the plate, but do not touch it. You must understand that there are annular cracks round each pin on the upper surface. You will see a plan view of the arrangement in the centre of the diagram. The central circle represents the end of one of the pins, and the larger circle the end of the orifices in the upper plate. The annular cracks are filled with selenium. There is one point to which I will draw your attention, and that is, the conical shape of the perforations in the upper plate. On account of that arrangement, the points of closest approximation between the pins and the plate are upon the upper surface. Now, as the action of light upon selenium seems to be a surface action, this is a special advantage, as throwing the whole current along the surface of the selenium.

The method of annealing selenium which is usually employed is to place the selenium cell in a cylindrical pot with a thermometer, connecting it with a galvanometer and a battery. It is placed inside a pot filled with linseed oil, and the whole is heated over a gas-stove. The temperature rises to about 210° C., and it is retained at 210° C. for many hours—generally about 24 hours in our experiments—and then the whole arrangement—pots and selenium cells—is packed in a box arranged to retard radiation of heat, so that it takes 40 to 60 hours to be cooled down to the temperature of the air. When the selenium

is removed, it is found to be a conductor, and very sensitive to light.

In the experiments of Mr. Tainter and myself, we have devised very many different forms of selenium cells, but it would not do to take up your time by entering too much into the *minutiae* of this. I shall simply direct your attention to the form of the cell that I am using in my experiments at the present time, a specimen of which is before you now. The selenium cell is cylindrical in shape; in fact, it looks somewhat like a reel of cotton. It consists of numerous brass discs, separated by discs of mica, slightly smaller in diameter than the brass discs. You will understand that when these discs are arranged alternately, you have a large number of annular grooves between the adjoining brass discs and over the edge of the mica; these are filled with selenium, and we have, in this form of cell, about 100 of these selenium rings. By an arrangement, which it is unnecessary to describe to-night, alternate brass discs, Nos. 1, 3, 5, 7, and so on, are metallically connected together, and all the even numbers are connected together, the odd numbers being connected to one pole of the battery, and the even numbers to the other; then the only means for the current to pass is through the selenium rings, and on account of the large number of the rings the resistance of this cell is very small. We prefer the cylindrical shape, because the apparatus can be placed in the focus of a parabolic reflector, and a beam of light coming from a great distance, may be caught by the reflector and brought on to the selenium surface of the cylindrical cell. In selenium cells of the description I have shown you, the resistance is extremely small. An improvement has been made in the method of annealing also. Hitherto the preparation of sensitive selenium has required very many hours, but we can now prepare it in a very few minutes. A cylindrical selenium cell, like that I hold in my hand, is placed in a lathe, and is kept rotating over a gas flame, the cell being protected from the direct action of the flame by a sheet of metal. When the brass is hot enough to melt a stick of selenium applied to the surface, it is rubbed over it, so that we have a uniform surface of selenium. The arrangement is then allowed to cool, but the selenium obtained in this way is a non-conductor, or has a very high resistance. In order to reduce the resistance, and give it sensitiveness to light, we re-heat the selenium over a gas-stove. In the original, amorphous, non-conducting condition, it is black, and shines by reflected light, but as you heat it a remarkable change in its appearance takes place. It crystallises during the heating process, and becomes like frosted silver or lead, or, at all events, it looks like metal. Now, if you continue the heating process at a certain temperature—say  $270^{\circ}$  C.—this crystalline selenium melts; the moment we observe the first signs of melting, the gas is immediately turned out. No special precaution is taken with regard to cooling the selenium, but it is found on cooling to be a conductor, and to be sensitive to light. Cells of this description have generally a resistance of about 300 ohms, and a sensitiveness of about one-half; that is, the resistance is reduced to-half when it is exposed to a bright light. Prof. Adams has shown that the

resistance of selenium is reduced in some proportion to the intensity of the light that falls upon it. One result of his researches was to suggest to my mind, that by varying the intensity of the light falling upon selenium, and observing its conductivity, not with the galvanometer, but with the telephone, we might be able to produce sounds from the telephone. The laws of audibility of the telephone is precisely analogous to the law of electric induction. No sound is produced, so long as you pass a continuous and steady current of electricity through the telephone; it is only at the moment of change from a stronger to a weaker condition, or *vice versa*, that any audible effect is produced; and the amount of sound is precisely proportionate to the amount of variation in the current. Hence, when a beam of light is allowed to fall on a piece of selenium which is connected with a telephone and galvanic battery, no effect is produced, so long as the beam shines steadily and continuously, but the moment you vary its intensity from a stronger to a weaker condition, or *vice versa*, you vary the resistance of the selenium; in like manner you vary the strength of the electric current traversing the current; in like manner you vary the power of the magnet in the telephone, the plate of the telephone is attracted or released, and the sound is produced from the plate of iron. If, then, we can vary the intensity of the beam of light in such a manner as to produce variation in the strength of the electric current traversing the telephone, corresponding to the variations in the air produced during the utterance of any vocal or other sound, we shall have produced from that telephone a reproduction of the original sound.

In carrying this idea into execution, it is of course necessary to devise an apparatus by means of which the intensity of a beam of light may be controlled by the voice. Mr. Sumner Tainter and I have devised a large number of forms of apparatus for producing this effect, but I shall only occupy your attention to-night by showing you two of the most successful forms that have been constructed.

In the form of articulating photophone now shown, we have a perforated screen attached to a diaphragm which can be actuated by the voice of a speaker. There are two similarly perforated screens, one behind the other. In the normal condition of the apparatus, the slits in the one screen are almost superposed upon the slits of the other, so that there are slight apertures through which light can be passed, but it will be understood that upon passing bright light through the double screen, and speaking into the apparatus, the movable screen is caused to slide backwards and forwards by the vibration of the diaphragm, thus partially closing and opening the minute orifices for the passage of light. Thus the vibration of the screen, under the action of the voice, controls the amount of light that is passed through. In arranging the apparatus for the purpose of transmitting speech to distance, a parallel beam of light is employed so that as little dispersion as possible take place. You can see on the screen the fixed grating and the movable grating attached to the diaphragm. The light is passed through the double grating, and at some distant point is condensed by means of a lense on a selenium cell

which is connected with a galvanic battery and telephone. Now the action of the apparatus will be understood. When a person speaks into the tube, more or less light is allowed to pass through, in accordance with the vibration of the plate. You then have a varying beam of light; the amount of light that reaches the distant station varies in proportion to the motion of the plate; that is, in proportion to the motion of the particles of air that actuate the plate; that is, in proportion to the vibration of the voice; the electric resistance of the selenium being affected proportionately to the intensity of the light falling upon it. Thus we have in the telephonic circuit a constantly varying current of electricity produced, the variations of which correspond to the variations of resistance in the selenium—correspond to the variations in the amount of light transmitted by the double grating—correspond to the variations of the speaker's voice—and we know the result; the articulations of a distant speaker are reproduced by the telephone at the listener's ear, although no conducting wire is found between the transmitter and the receiver. I may say, that in this form of apparatus, Mr. Tainter and I have succeeded in carrying on a conversation when the transmitter and the receiver were separated by a distance of about 280 feet. But a very curious effect of articulation was produced. The articulation reminded me of the early forms of telephone, which were shown to the world in the spring of 1876. In a paper read before the American Academy of Arts and Sciences, in May, 1876, I analysed the pronunciation of the telephone as then constructed, and found that, while the vowels were very accurately reproduced, the consonants were very imperfect. It was the same with this form of photophone, and I will give you an illustration of this peculiarity. The transmitted instrument was placed at the open window of my laboratory in Washington, with a selenium receiver a few feet away, and the telephones connected with the selenium receiver were placed in the basement of the same building, out of earshot. A friend then spoke to the transmitter. I, listening at the telephone in the basement, heard the tones of the voice very distinctly, with a great deal of the articulation; familiar sentences, such as "How do you do?" "Do you hear what I say?" "One, two, three, four, five," and such common phrases as these, were easily understood; but, on asking any friend to repeat sentences of the nature of which I could have no previous idea, I was unable to understand the articulation. On coming upstairs I repeated, as nearly as possible, the sounds that I had heard; that is, I gave utterance to a string of gibberish; but, upon comparing this gibberish with the actual sentence that had been uttered, I found that the vowels in the gibberish were identical with the vowels in the sentence. I then asked my friend to repeat another sentence that I could not guess, and the result was rather amusing, and illustrates this same peculiarity of the articulation. Upon going downstairs, and placing the telephone to my ear, I could hear the sentence, "A good piece of bread; a good piece of bread; a good piece of bread." I listened for about twelve or fourteen times, and this sentence was repeated, and the articulation seemed perfect. I then went upstairs, and said to

my friend, "I understood it this time; you said 'a good piece of bread.'" He said; "No; I said—'put me to bed.'" It will be observed that the vowels in these two sentences are the same; the consonants alone were defective. I may say, in passing, that our neighbours on the opposite side of the street, seemed very much astonished at the sight of a young man at an open window, shouting, in broad daylight, "put me to bed."

I shall now have the pleasure of showing you the form of apparatus in which the defects of the articulation have been remedied. We now simply speak against the back of a looking-glass that is made of very thin and flexible material. We use microscope glass, silvered by the ordinary process for silvering specula for the telescope. I am holding one of these in a beam of light, so that you may see the reflection produced by the disc. Upon speaking to this disc, it is thrown into vibration and moved backwards and forwards, becoming alternately convex and concave; and you will observe on the screen the effect produced by simply breathing upon it; the beam of light is alternately condensed and scattered; and the intensity of the light falling on the screen is constantly varying under the vibration, of the plate. I can speak to this, but of course the vibrations are too rapid to be followed by the eye. I shall make a trilled r, and I think in this case you will be able to observe the vibrations of the disc. [Mr. Bell here showed the vibration of the mirror under the sound of rrr, and also the effect produced by articulating the numerals from 1 to 20.]

You will now understand what I have ventured to term an undulatory beam of light, for want of a better expression. By an undulatory beam of light, I mean light that shines continuously on a sensitive receiver, but the intensity of which upon that receiver is constantly varying, in a manner corresponding to the vibration of some sound. The form of apparatus you have seen shown in section in the last illustration. The speaker's voice is directed against the silvered diaphragm through a speaking-tube; the portion of light striking the diaphragm is reflected as a parallel beam, but, on speaking to the diaphragm, it becomes alternately convex and concave, scattering and condensing the light, and making it what I call an undulatory beam. On arranging the apparatus for the purpose of transmitting speech to a distance, Mr. Tainter and I have found the following arrangement advisable. The actual apparatus by which the result is achieved is shown on the table. A beam of sunlight, or a parallel beam of light from any source, is reflected from a plane mirror through an achromatic lens, and brought to a focus upon or near the diaphragm mirror. After being reflected, the rays are again brought parallel, as nearly as possible, by a second lens, and at a distant station the light is received in a parabolic reflector, in the centre of which is the selenium receiver. It is found in actual practice, in utilising sunlight for this purpose, we are very apt to crack our glass, on account of the great heat at the focal point, and yet we want great concentration of light in order to allow for some loss, because we must have some loss in transmitting to a great distance, so we place the focal point not on the mirror, but near it, and place in the path of the beam a concen-

trated solution of alum, for the purpose of absorbing the heat rays of low refrangibility, to protect the mirror as much as possible. You will understand that telephones are connected with the selenium receiver and a battery. You will also understand that when a person speaks to this mirror, the intensity of the beam of light is constantly changed, the electric resistance of the selenium is constantly changed, and the sound that is taken into the transmitter is reproduced by the telephone in circuit with the selenium.

In experimenting with this apparatus, we have been unable to attempt the reproduction of speech at a great distance on account of the necessary privacy of our experiments; but we have succeeded admirably at the greatest distance we have tried. I may give you an account of the first experiment that was made at a great distance. The transmitting instrument, similar in construction to the apparatus here shown, was placed on the top of the Franklin School-house, in Washington, and the selenium receiver inside a parabolic reflector—the identical receiver that we have here to-night—was placed in the window of my laboratory in L-street in the same city, the distance between the two being a little over 800 feet. It was impossible to communicate by word of mouth across that distance; and, while I was observing Mr. Tainter on the top of the school-house, almost blinded by the light that was coming in at the window of my laboratory, and vainly trying to understand the gestures he was making to me at that great distance, the thought occurred to me of listening to the telephone connected with the selenium receiver. Mr. Tainter saw me disappear from the window, and at once spoke to the transmitter. I heard distinctly what he said:—"Mr. Bell, if you hear what I say, come to the window and wave your hat." It is needless to say with what gusto I did wave my hat.

It is almost always the case that when we follow up one path of investigation, another opens upon our attention, and in the course of reducing to practice the idea of the photophone, as described to you to-night, Mr. Tainter and I have been led to a discovery of the greatest possible interest to the scientific world. Of course we all know that the molecular vibration, or disturbance in a rod of iron by the magnetising influence of an intermittent magnetic current can be heard as sound by placing the ear in direct contact with the rod of iron, and it occurred to us that a molecular disturbance of any kind, and however produced, if rendered intermittent, should in like manner be observed as sound by placing the ear in close contact with the substance. Now we know in the case of crystalline selenium that a molecular disturbance is produced by light. It is usually manifested to our senses through the medium of an electric current; but, if this theory were correct, this molecular disturbance should be developed as sound by placing the selenium in close contact with the ear, and rendering a beam of light intermittent. The form of apparatus for experiments on the question is on the table before me, and it may be well to show you on the screen the mode of using it. The light is rendered intermittent by being passed through one of the orifices in a perforated wheel, and as the actual apparatus is on the platform, it will not be necessary to

enter into any detailed description of it. I shall briefly show you the arrangement of the whole in a sectional view. A beam of sunlight is brought to a focus by means of a lens. The diameter of the surfaces in the perforated disc, is just the diameter of the image of the sun formed in the focus of the lens, so that all the light impinging on this lens passes through the minute orifices of the wheel. The divergent beam is then again rendered parallel, so that it may be transmitted to the distant station, and is there converged on a piece of selenium in circuit with the telephone. You will understand that the rotation of this wheel will render the beam of light, falling upon the selenium, intermittent, and if the beam is interrupted a sufficient number of times per second, a musical note is perceived in the telephone. Now, our idea was that we should hear that musical note without the aid of the electric current or telephone, by placing the ear in close contact with the selenium itself. We made many experiments with different pieces of selenium, and even with other substances, to see whether this effect was produced, but the results were entirely negative. A very curious observation, however, was made in the course of the experiments. It was our custom to interrupt the musical tone by placing the hand in the path of the ray. The moment the shadow of the hand fell on the selenium, the sound immediately ceased, and the moment the hand was taken out of the path of the beam, the sound came again. In the course of our experiments, we were led to substitute, instead of the hand, a thin sheet of hard rubber, which happened to be in the workshop. At the end of the diagram, you will see the selenium receiver and the hard rubber—an apparently opaque sheet of hard rubber or ebonite—placed in the path of the beam. Now, the discovery to which I direct your attention first, is the fact that the interposition of this opaque substance does not entirely cut off the sound; that something passes through the hard rubber that affects the electric resistance of the selenium, and produces a sound. The effect is still more remarkable when, in place of holding the india-rubber near the selenium itself, it is held on the other side of the rotating disc, so that no light reaches the rotating disc. An invisible beam is brought to a focus, is rendered parallel by a second lens, and is again brought to a focus by another lens, and a musical note is developed at the telephone. I do not pretend to say what the nature of these rays is, but it is difficult to believe that they can be heat rays, for, in the first place, hard rubber is a substance which becomes heated when exposed to the sun's rays, and does not, therefore, transmit heat rays to any appreciable extent. But, if we place in the path of the beam, two sheets of hard rubber, and between them a glass vessel containing a saturated solution of alum, the effect is still obtained. I do not pretend to say what the cause of this strange effect may be. I have already told you of our attempt to hear molecular disturbance in selenium directly, without the aid of an electric current, but it occurred to us on observing the anomalous behaviour of the hard rubber sheet, to place it to our ears in place of the selenium that we had been experimenting with. The arrangement is shown on the next diagram.

placed the sheet of hard rubber in close contact with my ear, while an intermittent beam of light was allowed to fall on the hard rubber, and a clear distinct musical note was the result, the pitch of which depended on the rotation of the wheel. That it was not in any way due to any acoustical vibration in the air, was proved by simply interposing the hand in the path of the beam. This would not have sufficed to prevent the audibility of aerial vibration, but it at once stopped the sound in the hard rubber. On using a sheet of hard rubber as a diaphragm, and listening to it, as shown in the next illustration, the loudness of sound was very much intensified. It then occurred to Mr. Tainter and myself that it might be necessary, in order to hear the molecular disturbance produced by light, that the substance could be in the state of a thin diaphragm, so we made a thin diaphragm of selenium, and the same effect was observed. A musical note was produced from the selenium directly, but the sound was not to be compared to that produced by the hard rubber; it was very much inferior in volume. But the curious fact comes out that all substances in the shape of a thin diaphragm emit sound when exposed to an intermittent beam of light. I have on the platform the various diaphragms with which we have experimented; all the metals, even paper, mica, glass, carbon, and all sorts of substances, in the shape of thin diaphragms, emit musical tones under the action of the intermittent beam. One other interesting feature is the difference in the intensity of the sounds produced by different substances, and this is a most interesting field of exploration for the scientific man. It occurred to us, as an explanation of the reason why it was necessary to use thin diaphragms for the different substances, instead of masses, was, that the molecular disturbance produced by light was chiefly on the surface, and the vibration had, therefore, to be transmitted through the mass of the substance in order to produce the effect. We thought, therefore, that if we could listen at the illuminated side of the diaphragm, we should hear the sound with greater distinctness. It is rather difficult to arrange apparatus suitable for this experiment; but the following form occurred to us. Instead of using a substance in the shape of a thin diaphragm, we used it in the shape of a tube. We first of all experimented with an ordinary rubber tube. The light was brought to a focus just at the mouth of the tube, so that the beam diverging from the focal point, struck the interior sides of the tube. We listened at the other end of the tube, and, of course, our ears were then in communication with the illuminated side. A distinct musical tone was heard, and every substance we have tried, in the shape of a tube, has emitted musical tones in this way. We can even hear sound when, in place of an artificial tube, we focussed the light into the interior of the ear itself.

Another form of this experiment has occurred to me since my arrival in Europe; and the sun, very fortunately, coming out for a few hours, while I was in Paris, I was enabled to put it into execution with success. If we take a transparent vessel, such as a test-tube, we can place inside it substances in any physical condition—in the solid liquid or gaseous state—and by con-

necting the open mouth of the test-tube with a hearing-tube, we can listen while we throw an intermittent beam of light on the substance through the transparent glass of the test-tube. All the substances that I was able to try in the short time at my disposal yielded musical notes, with the exception of water and chlorate of potash in the state of powder. Crystallised sulphate of copper gave a very beautiful note. A whole cigar placed in the test-tube also emitted quite a loud note; but the best sound I think was produced by some little chips of pine wood dropped into the tube. It is not necessary that the substances should be solid or liquid; it is sufficient to fill the test-tube with tobacco smoke, and the musical note is produced, whereas without the tobacco smoke no sound, or a very slight sound, is developed. I have been able to repeat these experiments, within the last few days, at the Royal Institution, with the aid of your artificial sun (for we cannot hope to have the natural sun in London in November or December), the electric light. Professor Tyndall suggested a modification of the experiment that has also proved successful—to fill this tube with an absorbent gas. We placed a few drops of sulphuric ether at the bottom of the test-tube, and then submitted the perfectly transparent test-tube to the action of the intermittent beam of light. A distinctly audible, but feeble, musical tone was the result, and this is very suggestive and very significant, as it seems to prove that the action is strictly a molecular action, and that we can hear even in a gas the result of a molecular vibration. I have taken up a great deal of time, and I must thank you very much for the way in which you have listened to me to-night. I only wish that I could show you instruments in operation, but the effects produced, though perfectly demonstrable, are too feeble to be satisfactory to an audience like this. We require great quietness and a good light. If we only had the sunlight here, I should have no hesitation in making the experiments, but as it is, we are obliged to confine our experiments to a few scientific men, working at such a laboratory as that of the Royal Institution.

#### DISCUSSION.

The Chairman having invited Dr. Siemens to explain his "Selenium Eye,"

Dr. Siemens, F.R.S., said he had listened with intense interest to the discourse which Professor Graham Bell had given. The world had been astonished before with his invention of the telephone, and now he came forward with an instrument equally marvellous in its results. The property of selenium to alter its electrical resistance under the influence of light, was, as had been stated first brought before the world by Mr. Willoughby Smith, and so remarkable was this discovery that many physicists turned their attention to the subject. His brother, Dr. Werner Siemens, took up the inquiry with a view of determining the cause of this extraordinary variation in resistance caused by light, and the conclusion to which his researches, which were communicated to the Berlin Academy, led him, was that the resistance of selenium, and probably, indeed, of all substances, varied inversely to the amount of heat which they contained; and the reason why selenium showed such extraordinary changes under the influence of light was, that under that influence, it changed from one aggregate condition to another—from an amorphous to a crystal-

line condition; and that at the moment when this change took place, a great deal of heat was absorbed, and therefore the specific heat of the selenium was very much increased. This was strictly a molecular change, and bore on the further discovery which Professor Graham Bell had made, that he could hear the changes going on even in gaseous bodies, produced by the passage of light. The little instrument which he (Dr. Siemens) had constructed to show the members of the Royal Institution was on the table. It had the form of an eye, and on opening the lids, a lens was presented to the light; through that lens, the light, falling upon it, was concentrated upon a spot in the interior of the ball. At that spot one of the selenium gratings, which had been described, was placed, a grating not larger than a threepenny piece, consisting of five wires laid in zigzag fashion; one wire was connected to the positive, and the other to the negative pole of a battery. These wires, lying close together, but not touching, were laid on a plate of mica; a drop of selenium was placed upon them, and this small quantity sufficed to produce the desired results. The principal object he had in devising it was to construct a selenium photometer; but a difficulty arose in using it for that purpose, because selenium got fatigued under the influence of light. The eye, after being exposed for any considerable period to an intense light, became insensitive, and the lids had to be closed; it had to go to sleep for some time before it regained its sensitiveness, and the analogy to the human eye went even further than that. If the eye were used after having been kept in the dark for a length of time, it would detect the slightest gleam of light, and mark it on the galvanometer, whereas after it had been once used in intenser lights, a small gleam would be utterly lost upon it, until it had again had ample rest. The instrument before them had not been used for some years, and it might still be active, but the audience would have to take the Chairman's word for it, since the galvanometer in circuit with the "eye" was not one whose indications were visible to a number of persons at once. [Dr. Siemens then experimented with variously-coloured sheets of cardboard prepared for the purpose, and the reflected light was found to cause a deflection of the galvanometer in each case, the slightest effect being produced with light reflected from a black piece of paper, and successively increasing with green, red, and white, the greatest of all being produced by exposing it to the direct light of an argand burner.] These experiments showed the great sensitiveness of selenium; but Professor Bell had gone much further, and had prepared an instrument with concentric plates of selenium and intervening plates of mica, and operating upon a much larger surface. He had gone much further than had been done previously. Then came the further step which he had so boldly taken, of making light become the carrier of speech. As he had justly said, this seemed marvellous at first, but when you knew how to do it, it became simple, like everything else, and he (Dr. Siemens) must congratulate the Society on having had the method of doing it so clearly explained.

Mr. W. H. Preece referred to the high honour which Professor Graham Bell had done him in asking him to bring before the English public his great invention of the photophone, and said he had willingly undertaken the task, but had had to give it up in consequence of another event with which Professor Bell was indirectly connected. It was an immense relief to him to find that just as he had written to the secretary to say that he could not read a paper, Professor Bell himself telegraphed to say that he was coming, and the consequence was they had had one of the pleasantest evenings he had ever spent in that room. It was not only the beauty of the discoveries, and the clear manner in which they had been described, which he admired, but the truly scientific way in which they were followed up, and the way in which the matter had grown in the hands of Pro-

fessor Bell and Mr. Tainter, until it burst out like a flower in full bloom. And there was another interesting point in connection with this instrument, and that was that, following the excellent example of Professor Hughes, Mr. Bell had thrown this investigation open to the public, unrestricted by any patent. They had heard a great deal, at different times, of the efforts made to try and extract ideas from nature; one had talked about bringing down lightnings from heaven, another spoke of bringing "spirits from the vasty deep," and another spoke of "the music of the spheres;" but, to-night they had seen how a patient, plodding philosopher could go to the other extreme, and make those little molecules which the eye could not see, and the mind scarcely grasp, imitate the beautiful modulations of the human voice. Professor Bell had caused a great deal of trouble to practical men, especially to telegraph engineers, by forcing them to deviate, to some extent, from their own sphere, and study the science of sound, but now he had compelled them also to go into the study of light; but they were indebted to him, not only because he had added to their practical apparatus a useful appliance, but because of the interesting and singularly beautiful nature of his discoveries.

Professor Hughes, F.R.S., being next called upon by the Chairman, merely expressed his admiration of the apparatus.

The Chairman said it only remained for him to discharge a work of supererogation by proposing a vote of thanks to the lecturer. They had had the matter put before them by Mr. Preece, in language more worthy of a poet than of a chief telegraph engineer, and in a way they would always remember. He could not pretend to emulate that style, nor to speak adequately on the subject of the evening, but the audience might consider for a moment what they had had brought before them—the intimate connection of those things which used to be considered three separate subjects of study, and three distinct sciences—electricity, light, and acoustics. Professor Bell had shown them that the three had so intimate a connection that it was perfectly possible, where there was adequate light, and the means of transmitting it from place to place, not indeed to make that light the conveyor of sound, but to make it reproduce, at a distance, the sound which in the outset caused the light to vary in its intensity. It was a matter which, if the present generation were capable of surprise at any scientific discovery, would certainly surprise them. Would not the proposition have been said to emanate only from one worthy of a distinguished position in a lunatic asylum—the proposition, "I desire to convey sound to a distance: I have no means of doing it excepting by a ray of light." It would have been said at once, "You cannot do it; that is not a means; it is incredible and impossible;" and it might have been so said even after Professor Bell's wonderful discovery of the telephone. When they first heard of that, it struck them as one of those wild suggestions which occasionally were made, and came to nothing. Only about a year ago they saw in the public prints that some person in Australia had discovered a means of sending human beings and animals to sleep for any length of time required, and they were told they were to get fresh meat from Australia, by sending animals over in a somnolent state, to be woke up to be killed. They all laughed at that, because it did not turn out to be true; but it might have been true, and if it had been, it did not seem to him so wonderful as the statement:—"I wish to repeat a sound that has been heard in London, in a village 10 miles off. I have no means of doing it, except the sun's rays, and I will do it with that." Nobody making that statement would have been entitled to belief, but yet Professor Bell had brought it into the range of an accomplished fact. Unhappily, it was one of those delicate experiments which could

only be shown before a chosen few, and in places well adapted for the purpose. The great advantage of having a subject of this kind taken up by a man of Professor Bell's calibre of intellect, was this—that as he went on experimenting, new circumstances arose, and he had brought forward that evening such a list of suggestions for extended inquiry in physics, as would occupy the scientific men of Europe for many years to come. In conclusion, he (the Chairman) hoped that, as many had been unable to attend the lecture that evening, Prof. Bell, if he could not repeat the lecture, as he did that on the telephone on a former occasion, would obtain a promise from Mr. Preece to do it for him.

The vote of thanks having been passed unanimously,

Professor Graham Bell, in thanking the meeting, said he wished it were in his power to accede personally to the Chairman's request, but engagements on the other side of the Atlantic would make this his last lecture on this subject in Europe. He would, however, do his best, with great pleasure, to prevail on Mr. Preece to fulfil the request which had been made.

### "DESCHUGARA," A NEW CEREAL AND FORAGE PLANT.

A new forage plant is announced from Central Asia, under the name of "Deschugara." It is said to be largely cultivated in Turkestan, as well as in Poland, where it has given most satisfactory results. From 100 lbs. of seeds sown, 2,800 lbs. of grain have been harvested, and a large quantity of straw, which is consumed with avidity by cattle and sheep. The plant has a tall-growing, stout stem, which forms a green cattle food. A variety of the plant ripens three months after being sown. In the climate of Odessa it is described as arriving at maturity as soon as it does in its own country. The chemical composition of the plant approaches very nearly to that of the oat and barley, so that it is extremely useful as a cattle food. The seeds, however, reduced to powder, are used as ordinary flour. Some mystery attended the botanical identification of this plant, when its properties were first made known in the pages of a continental journal some few weeks since. Mr. Christy has, however, succeeded in obtaining some seed from Russia which, together with information he has also obtained, prove the plant to be that of *Corythum ceruum*, a grass closely allied to the well-known Dhurra of India.

### CORRESPONDENCE.

#### PEPPERMINT TEST FOR DRAINS.

It seems to me that the Boston plan of using oil of peppermint (described in the *Journal* of November 19), is rather clumsy, inasmuch as the small quantity of oil used might stick in some crevice and not be washed out by the two pails full of water, by which it is followed. I prefer to shake up the oil thoroughly with water in the largest available bottle, before pouring it down. It does not dissolve in the water, nor does it really mix with it, but it forms a strong-smelling emulsion, which answers the purpose just as well as a true solution in alcohol would. It would be interesting to know what quantity of the oil the small bottles contain, which are to be bought in Boston at two dollars the dozen, or about eightpence each, and whether the quality is at all equal to English Mitcham oil. Our practice at present is to use an ounce of the Mitcham oil for each house

that we test, and that costs 2s. 6d. We have tried the foreign oil, which can be bought at about half the price, but we find that it is only half as strong, or in other words makes only half the quantity of emulsion, so that there is no economy in using it. What we want is that some manufacturer would make an oil as strong smelling as the Mitcham oil, but not so highly refined, and which could be sold cheaper. As the demand increases we have no doubt that this will be done. Our experience is the same as that of the Boston people as to the necessity for the person who pours the oil down not mixing among those who are trying to detect any escape of it from drains or pipes, as he brings an amount of the vapour adhering to his clothes, which makes accurate observation of leaks impossible.

Ether, which we formerly used, was not so bad in that respect, but it was too expensive, and also rather dangerous, so we always use oil of peppermint now.

COSMO LIXES.

7, John-street, Adelphi.

### "HAYDON'S PICTURES TO THE COAL-HOLE!"

Although such were the words recited to me by Sir Martin Archer Shee, it is but justice to Haydon to say that he denied them. It so happens that I am, by chance, reminded of this. In 1842, I reviewed Haydon's lectures on "Fresco," in the "Civil Engineer and Architects' Journal" for 1842, vol. v., and introduced the coal-hole anecdote. At p. 201 is a characteristic letter by Haydon in reply to the review, and denying the anecdote. At p. 388 is another curious contribution on Wilkie, and at p. 413, one on schools of design by Haydon.

HYDE CLARKE.

32, St. George's-square, S.W.,  
29th November, 1890.

### OBITUARY.

G. W. Yapp.—By the death of Mr. G. W. Yapp, on the 15th November, at the age of 69, the Society loses a frequent correspondent to the *Journal*. Mr. Yapp, born in London, was the son of a naval officer belonging to an old Herefordshire family. He was connected by family ties, among others, with Sir Walter Scott, Dickens, and Douglas Jerrold. In early life he was trained in the secretariat of Joseph Hume, but he entered too late to benefit materially by that economist's patronage. He commenced his literary work in 1837, as a writer for the "Penny Cyclopædia." He proposed a plan for the formation of the Parliamentary library at the Reform Club, and assisted materially in carrying it into execution. In 1851, Mr. Yapp compiled the catalogue of the Great Exhibition of 1851. He was for a long time an agent in London and Paris for a patent firm at Washington. His exhibition connexion took him to Paris, where he was in 1855, and he there compiled "Duties on Imports into France." He had collected the materials for a technological dictionary, French and English, which was never published. In 1858 and 1859 he was Paris correspondent of the *Daily Telegraph*. He prepared the English translation of the Official Catalogue in 1867, and which was presented to the Emperor some hours before the French edition. He unfortunately staid in Paris during the siege, and suffered its terrible vicissitudes, losing there one of his children, and laying the foundation of mortal illness for himself and another child. His account of the siege appears in the "History of the Franco-German War" Mackenzie, Glasgow).

## MEETINGS OF THE SOCIETY.

## ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock. For meetings previous to Christmas:—

DECEMBER 8.—"London Fogs." By Dr. ALFRED CARPENTER. EDWIN CHADWICK, C.B., Vice-President of the Society, will preside.

DECEMBER 15.—"The Use of Sound for Signals." By E. PRICE EDWARDS, Secretary to the Deputy-Master of the Trinity-house. Dr. TYNDALL, F.R.S., will preside.

For Meetings after Christmas:—

"Buying and Selling; its Nature and its Tools." By Prof. BONAMY PRICE. On this evening Lord ALFRED S. CHURCHILL will preside.

"Causes of Success and Failure in Modern Gold Mining." By A. G. LOCK.

"The Participation of Labour in the Profits of Enterprise." By SEDLEY TAYLOR, M.A., late Fellow of Trinity College, Cambridge.

"The Gold Fields of India." By HYDE CLARKE.

"Flashing Signals for Lighthouses," By Sir WM. THOMSON, F.R.S.

"The Present Condition of the Art of Wood-carving in England." By J. HUNGERFORD POLLEN.

"Five Years' Experience of the Working of the Trade Marks' Registration Acts." By EDMUND JOHNSON.

"Trade Prospects." By STEPHEN BOURNE.

"The Manufacture of Aërated Waters." By T. P. BRUCE WARREN.

"The Compound Air Engine." By Col. F. BEAUMONT, R.E.

"Improvements in the Treatment of Esparto for the Manufacture of Paper." By WILLIAM ARNOT, F.C.S.

"Deep Sea Investigation, and the Apparatus used in it." By J. G. BUCHANAN, F.R.S.E., F.C.S.

"The Discrimination and Artistic Use of Precious Stones." By Prof. A. H. CHURCH, F.C.S.

"Forest Conservancy in India." By Sir RICHARD TEMPLE, Bart., K.C.S.I.

"The Tenure and Cultivation of Land in India." By Sir GEORGE CAMPBELL, K.C.S.I., M.P.

"Indian Agriculture." By W. R. ROBERTSON.

"Trade Relations between Great Britain and her Dependencies." By WM. WESTGAERTH.

"The Languages of South Africa." By R. CUST.

"The Loo Choo Islands." By Consul JOHN A. GUBBINS.

## CANTOR LECTURES.

Monday Evenings, at eight o'clock. The First Course, on "Some Points of Contact between the Scientific and Artistic Aspects of Pottery and Porcelain." Five Lectures, by Prof. A. H. CHURCH, M.A. Oxon., F.C.S.

## LECTURE III.—DECEMBER 6.

Stoneware and other wares glazed with salt.

## LECTURE IV.—DECEMBER 13.

Soft paste porcelains, European and Oriental.

## LECTURE V.—DECEMBER 20.

Hard paste porcelains, Chinese, Japanese, and European.

The Second Course will be on "Watchmaking," by EDWARD RIGG, M.A. Three Lectures.

The Third Course will be on "The Scientific Principles involved in Electric Lighting," by Prof. W. G. ADAMS, F.R.S. Four Lectures.

The Fourth Course will be on "The Art of Lace-making," by ALAN S. COLE. Three Lectures.

The Fifth Course will be on "Colour Blindness and its Influence upon Various Industries," by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

## ADMISSION TO MEETINGS.

Members have the right of attending all the Society's meetings and lectures. Every Member can admit *two* friends to the Ordinary and Sectional Meetings, and *one* friend to the Cantor Lectures. Books of tickets for the purpose have been issued to the Members, but admission can also be obtained on the personal introduction of a Member.

## MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 6TH...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. A. H. Church, "Some Points of Contact between the Scientific and Artistic Aspects of Pottery and Porcelain." (Lecture III.)

Farmers' Club, Inns of Court Hotel, Holborn, W.C., 4 p.m. Annual General Meeting. Mr. Clare Sewell Read, "America and its Farming."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Society of Engineers, 6, Westminster-chambers, 7½ p.m. Mr. Frank W. Grierson, "The National Value of Cheap Patents."

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 7, Adelphi-terrace, W.C., 8 p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Leslie Stephen, "The Relation of Morality to Literature."

TUESDAY, DEC. 7TH...Civil Engineers, 25, Great George-street, Westminster, S.W., 8 p.m. Mr. Theophilus Seyd, "The Different Modes of Erecting Iron Bridges."

British Horological Institute, Northampton-square, E.C., 8 p.m. Mr. Edward Rigg, "Friction."

Pathological, 53, Berners-street, Oxford-street, W., 8½ p.m.

Biblical Archeology, 9, Conduit-street, W., 8½ p.m.

WEDNESDAY, DEC. 8TH...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Dr. Alfred Carpenter, "London Fogs."

Geological, Burlington-house, W., 8 p.m.

Microscopical, King's College, W.C., 8 p.m. 1. Dr. Hudson, "*Flascularia trifolium* n. sp." 2. Mr. C. Stewart, "Some Structural Features of *Echinometidae*." 3. "Notes on the Movements of Diatoms, the Construction of Object Glasses, Swinging Substages, &c."

Royal Literary Fund, 10, John-street, Adelphi, W.C., 3 p.m.

Telegraph Engineers, 25, Great George-street, S.W., 8 p.m. Mr. W. H. Preece, "The Photophone and the Conversion of Radiant Energy into Sound."

THURSDAY, DEC. 9TH...Royal, Burlington-house, W., 4½ p.m. 1. Major Herschel, "A Simplified Form of the Torsion Gravimeters of Broun and Babinet." 2. C. Schröter, "Note on the Microscopic Examination of some Fossil Wood from the Mackenzie River." 3. Dr. Hopkinson, "Electrostatic Capacity of Glass." II. 4. Dr. Urban Pritchard, "The Cochlea of the *Ornithorhynchus platypus* compared with that of Ordinary Mammals and of Birds."

Antiquaries, Burlington-house, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 7 p.m. Dr. Lionel S. Beale, "The Germination and Propagation of Disease."

Inventors' Institute, 4, St. Martin's place, W.C., 8 p.m.

Royal Society Club, Willis's-rooms, St. James's, S.W., 6 p.m.

Mathematical, 22, Albemarle-street, W., 8 p.m. 1. Prof. Teixeira, "Note sur Détermination des Déterminants." 2. Mr. W. B. Grove, "The Solution of the Inverse Logical Problem." 3. Mr. T. Craig, "Motion of a Viscous Fluid."

FRIDAY, DEC. 10TH...Froebel Society (at the House of the Society of Arts), 6 p.m. Annual Meeting.

Folk Lore Society, 22, Albemarle-street, W., 8 p.m. Mr. John Fenton, "The Birth of a Deity; or the Story of Unkulunka."

Astronomical, Burlington-house, W., 8 p.m.

Quekett Microscopical Club, University College, W.C., 8 p.m.

Clinical, 53, Berners-street, W., 8½ p.m.

SATURDAY, DEC. 11TH...Physical Science Schools, South Kensington, S.W., 3 p.m. 1. Lieut. L. Darwin, "The Rate of Loss of Light from Phosphorescent Surfaces." 2. Dr. Alder Wright, "The Determination of Chemical Affinity in Terms of Electromotive Force."

Royal Botanic, Inner-circle, Regent's-park, N.W., 3½ p.m.

## L OF THE SOCIETY OF ARTS.

No. 1,464. VOL. XXIX.

DAY, DECEMBER 10, 1880.

*Memorials for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## FORM OF THE PATENT LAWS.

ncil adopted the following Petition to  
of Commons, at their meeting on Mon-  
st.—

IGHT HONOURABLE THE COMMONS IN  
PARLIAMENT ASSEMBLED.

able Petition of the Council of the Society  
Manufactures, and Commerce, incorporated  
charter,

H,—

the Society is deeply interested in the  
r, and submits that it ought to be made  
, as far as possible, to the progress of  
Manufactures, and Commerce of this  
o as to allow the inventions of the  
igdom to compete fairly with those of  
ld.

the Society, in the years 1850, 1851, and  
ished reports on the Patent-law as then  
nd that those reports were instrumental  
g Parliament and the Government to  
stent-law Amendment Act, 1852, which  
reformed the law.

the effect of such reform has been greatly  
te invention, and has so increased  
ts derived from Patent fees, that they  
each the sum of £180,000 a-year, of  
r about £40,000 are expended in con-  
h the administration of the law, leaving  
s a tax on the progress of invention.

your petitioners are of opinion that the  
etains some antiquated fictions which  
abolished; that it should be greatly  
and that, as Patents relate to Arts,  
res, and Commerce, all matters connected  
should be administered by persons  
nowledge of Arts, Manufactures, and  
and not by legal functionaries, how-  
nt.

your petitioners desire to call the atten-  
our Honourable House to the Patent  
which is in an unsafe, overcrowded,  
lthough it contains unique and valuable  
of those early mechanical inventions  
revolutionised the Arts, Manufactures,  
erce of the civilised world; that such  
quite unworthy of the Nation, and  
e replaced by a suitable building, con-  
ommodation for a Reference Library.  
itioners, therefore, pray your Honour-  
to cause the present Patent-law to be

amended, and its administration to be entrusted  
to the Lords of the Privy Council for Trade.

And your petitioners will ever pray.

Signed on behalf of the Council of the  
Society for the Encouragement of Arts,  
Manufactures, and Commerce,

H. TRUEMAN WOOD, *Secretary*.

The Council also appointed a Committee to  
draft a Bill for submission to the Government.

## JUVENILE LECTURES.

The usual short course of lectures, adapted for  
a juvenile audience, will be given by Mr. G. J.  
Romanes, F.R.S., on "Animal Intelligence."

The dates for the lectures will be Wednesday,  
29th December, and Wednesday, 5th January.

The lectures will commence at seven o'clock.  
As in former years, admission will be by ticket  
only. A sufficient number of tickets to fill the  
room will be issued to members in the order in  
which applications are received, and the issue  
will then be discontinued. Subject to these con-  
ditions, each member is entitled to a ticket admit-  
ting two children and one adult. All members  
who require tickets should apply at once, as there  
may be difficulty in accommodating those who  
postpone their applications until the date fixed  
for the lecture.

By order,

H. TRUEMAN WOOD, *Secretary*.

PRACTICAL EXAMINATIONS IN VOCAL AND  
INSTRUMENTAL MUSIC.

The next Examination in London will be held  
at the Society's House during the week com-  
mencing 10th of January, 1881.

The Examination will be held at three periods  
—morning, afternoon, and evening—viz., from  
10 to 1, 2 to 5, and 7 to 10 o'clock on each day  
of Examination. Candidates may select either  
of these periods, but, the number of candidates  
in these Examinations being large, no special  
day or hour can be arranged for. The numbers  
will therefore be arranged in order of application.  
The Examination for the Organ and Harmonium  
will be held in the evening only, and special  
arrangements will be made according to the  
number of applications.

The fee is 10s. for the Honours (including both  
vocal and instrumental Examination), and 5s. for  
the First or Second Class (vocal or instrumental)  
Examination. If vocal as well as instrumental  
music, or two separate instruments, be taken by  
the same candidate for the First or Second Class  
Certificate, a fee of 7s. 6d. must be paid.

The Certificates will be prepared as soon as

possible after the Examinations, and can be had upon application at the House of the Society of Arts, on or after 1st March, 1881.

No Certificate will be granted to any candidate for Honours who does not obtain a First Class in the practical portion of the Examination, either vocal or instrumental. Candidates holding one of such Certificates, obtained in a former year, need not again undergo this portion of the Examination, but should bring their Certificate for the Examiner's inspection.

The Examination of each candidate will be private; no one but the Examiner and the accompanist being present, unless it be a member of the Society of Arts' Committee. No list of candidates will be published.

Particulars will be forwarded on application to the Secretary, Society of Arts, John-street, Adelphi. No names can be received after 24th Dec. 1880.

## PROCEEDINGS OF THE SOCIETY.

### FOURTH ORDINARY MEETING.

Wednesday, December 8th, 1880; EDWIN CHADWICK, C.B., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Aird, David Alfred, 2, Sussex-gardens, Hyde-park, W.  
 Angus, Joseph, The Hermitage, Langly-lane, South Lambeth, S.W.  
 Biddiford, George Francis, Barnwood-lodge, Gloucester.  
 Clements, Hugh, 5, Park-terrace, Peckham, S.E.  
 Foster, Thomas Nelson, Allt Dinas, Bays-hill, Cheltenham.  
 Morton, Joseph, 39, Chespside, E.C.  
 Obach, Dr. E., 17, Charlton-villas, Church-lane, Old Charlton, S.E.  
 Ridpath, J. Lionel, 12, West Kensington-gardens, W.  
 Snelgrove, Horatio Richard, The Grove, Clapham-common, S.W.  
 Sykes, Fred. W., Gosport Mills, Huddersfield.  
 Traill, James Christie (of Rattar, N.B.), Castle-hill, Thurso, Caithness.  
 Vogel, Sir Julius, K.C.M.G., 135, Cromwell-road, South Kensington, S.W.  
 Ward, Frederick Peterson, 46, Hamilton-terrace, St. John's-wood, N.W.  
 Wright, John Brooks, 96, Buchanan-street, Glasgow.  
 Young, Charles E., 71, Clapham-road, S.W.  
 Young, Sir Charles Lawrence, Bart., 5, Ashburn-place, Cromwell-road, S.W.  
 Young, George, 7, The Terrace, Ryde, Isle of Wight, and 43, Dover-street, Piccadilly, W.

The following candidates were balloted for, and duly elected members of the Society:—

Brenchley, Samuel, Hunt Bridge-house, Matlock.  
 Cassiot, Charles, Elmwood-house, Upper Tooting.  
 Gundry, Joseph Pearkes, the Cottage, Bridport, Dorsetshire.

Jaques, Leonard, J.P., 18, Seymour-street, W.  
 Larton, Frederick, Brighouse, Yorkshire.  
 Nix, John H., 77, Lombard-street, E.C.  
 Noel, Hon. Henry, 17, Westbourne-terrace, W.  
 Northampton, Marquis of, Castle Ashby, Northants.  
 Ormerod, Thomas, Woodfield, Brighouse, Yorks.  
 Robertson, Sir D. Brooke, C.B., Athenæum Club.  
 Robertson, J. Murray, Lower Grove-house, Hampton.  
 Seymour, Major-General W. H., Travellers' Pall-mall, S.W.  
 Sheppard, Samuel Gurney, 31, Oxford-square, W.  
 Simmons, Charles J., 56, Leverton-street, Leighton, N.W.  
 Skaife, John Slade, 32, Milner-square, N.  
 Slade, Francis William, Eldon-pk., South Norwood.  
 Volk, Magnus, 40, Preston-road, Brighton.

The paper read was on—

### LONDON FOGS.

By Alfred Carpenter, M.D.

There are fogs and fogs. I am not about you to consider all kinds of those creations. is the fog which pervades men's brains, and from them the power of judging rightly separating truth from error. There is a fog may be aptly called error, ever seeming to put itself for the purpose of blurring the outline vision, of interfering with our power of pursuing a right path, and causing us to follow a one. This kind of fog, though fully in my is not the fog with which we have to deal to except it may be as a link connecting ours with the difficulties which beset its consideration. I do not propose to ask you to inquire its causes of the regular Scotch mist, which we through and through almost before you realise the fact that it is a fog, neither do I propose to upon the causes of those fogs which rise the bosom of the great deep, and are occasionally carried by the wind into all parts of our These are not the fogs I ask you to consider. are white fogs, seldom, if ever, producing darkness, except during the dark hours selves; they do not shut out all evidence the ruler of the day whilst he is above the horizon as if he were not. They do not cause the of the air to return to their roosts and impression that Nature has changed her. Neither is it with those mists which rise the bosom of Father Thames, or of any stream running, either above or under ground. These fogs will present themselves where there is a particular kind of change in meteorological condition of the atmosphere and when heat, moisture, and pressure rapidly altered in the necessary direction. fogs are all beyond the power of man to increase or decrease, to control or prevent. are natural events, which will happen in any man or of his works, and nothing that he will materially alter their incidence. At times exist everywhere in the lowlands of the Islands; they must be endured, but their evil may be, in a great measure, warded off by means based upon common sense. But are other fogs which are not primeval, which not exist everywhere, and which are produced the acts of man himself, and are caused by foolish works which need not continue in operation.

they are specially peculiar to great aggregations of people, and their densest points are always to the leeward of the masses which have produced them. Their worst effects date from the introduction of coal, which gave power into the hands of men to defy distance, and to bring millions, or a society of the million, into the close intercourse of a great city; but they are not to be found in all great cities, for aggregations of peoples, such as at St. Petersburg and Moscow, who do not burn coal in the wasteful way that we do, are not visited with them; neither are they found in the great cities of the East, which, from the natural warmth of their surroundings, do not want fires in a general way. I am not about to assert that the fogs I speak of are entirely caused at all times by fuel smoke. I am not about to assert that coal smoke is alone responsible for all the evils which belong to these fogs, but it is the principal factor which makes London and its suburbs tolerable as places of residence for certain institutions. It does materially add to the mortality of the metropolis, and at times it is the sole cause of conditions which prevent the proper enjoyment of that life which kind Providence intended for us. It is a main factor in the reduction of a high rate of mortality, arising from the absence of ozone, or of ozonised oxygen, and depreciation of oxygen capable of immediately acting upon changing organic matter. It also causes many of our public buildings to show signs of premature decay, and, day by day, is producing destruction of property which, if it could be stopped, and its value accurately estimated, would probably be sufficient to repay ten times over the cost of the works which are required to prevent this unnecessary and ruinous loss. It will be asked, how I am able to prove the truth of my proposition. That is the business now before us. I think it has been fully proved of late years, by the numerous fogs which have occurred in the midst of summer, shutting out the light of day, and producing an Egyptian darkness at times when ordinary fogs have not existed. It was fully proved by a fog which occupied the West-end of London the other day, and which caused a mid-day darkness on a September Sunday, which could be felt. That day had not been preceded by any cold weather, the barometer was high, and was rising; the thermometer was high, it was not falling, and the dew point was high. The air was still, there was no perceptible wind; there was, however, an exceedingly slight current, which, as I afterwards found, occupied within a narrow space nearly all the points of the compass. The centre of a circle thus produced was mainly at the West-end of London. Some magnetical changes, the nature of which was not apparent, led to the production of a dense atmosphere at 11.30 a.m., on September 16th, which indirectly caused gas-lights to appear at Buckingham Palace and other parts of Belgravia, obscured the sun at mid-day in as perfect a manner as it was possible to be obscured over a great town by human aid. I say advisedly, by human aid, because a few experiments made upon the spot proved that the darkness was caused by unconsumed carbon in the atmosphere: that he pall thus spread over the place was limited to a moderate elevation, not reaching

much above the tops of the houses, so that the tallest of them could in places be just seen peering above the dark cloud which rested upon the earth. When one was able to get outside the veil which hung upon the metropolis, its cause could be seen pouring down from every chimney which was acting as an upcast for a fire. The sun was quite invisible from the surface of the ground, but appeared as a copper-coloured disc from the upper windows in the houses in the Oxford-street side of Hyde-park. The sky was comparatively cloudless, but there was no warmth in the sun's beams over London, no comfort in his aspect, and not a shadow of heat could be collected by a pocket lens, although outside the pall the sun was shining brilliantly, and the country enjoying a perfect summer's day. The air was warm outside, temperature 64°. The grass in Hyde-park was perfectly dry, as shown when the hand was passed over it. The particles of black matter, which were collected on a similar occasion, on a microscopical glass slide moistened with glycerine, shewed the same appearances in the field of the microscope as that exhibited by a similar slide designedly exposed to the smoke of a common chimney, viz., particles of unconsumed carbon and some oily matter, which was of a tarry nature. There was also the other accompaniments of smoke in the air,—viz., an acid gas, which acted upon moistened litmus paper, and which, by the irritating effect which it had upon the bronchial mucous membrane, was something more than carbonic acid. Other tests showed that this was sulphurous acid, which existed so abundantly as to counteract the naturally soothing effect of the carbonic acid, which was also largely in excess. I have sometimes found ammonia, but on this occasion it was neutralised, if present, by the acid, and yet left sufficient of free acid to decidedly affect the bronchial mucous membrane. The air was not tested for ozone, but that none existed was very manifest. The openings from the public sewers gave unmistakeable evidence of a greater warmth below, which, telling upon the contents of the sewers themselves, produced a fermentation, obvious as to its origin; but, curiously enough, the smell was not perceived a few yards away from the gratings. I may be allowed to mention, in passing, that the presence of carbon and sulphurous acid in the atmosphere appeared to be of great use, altering the character of the emanations from the public sewers, and giving the inhabitants of this great city a present protection from the effects of one of the greatest engineering errors of the present time—one of those great mistakes which engineers are constantly making under the name of sanitary work, whilst they are breaking a fundamental or canon law of sanitary science. I may, perhaps, be allowed to give the ground of that law. Any sewer which becomes a sewer of deposit, either by accident or design, has been constructed in defiance of sanitary law, and must in due course bring insanitary results to those exposed to its influence: it is wrongly constructed, and is a mistake. I mention this point now, to show that the smoke of a great town is not an unmitigated evil, but that it has a mission, so to speak, which is not yet completed. It is a truism, nevertheless, that two wrongs cannot make a right. The right to pure air

ought not to be sacrificed to the necessity for impurity, because other works have failed to effect the object for which those works should have been constructed.

I must, however, now give further proofs that smoke is the cause of the darkness which these fogs produce. Fogs of all kinds are limited in the extent to which they reach upwards. Natural fogs do not reach an altitude sufficient to shut out daylight, for as soon as their ordinary depth reaches a certain extent, the fog lifts and floats away, or the meteorological changes are such as lead to its dispersion. So also with smoke fogs; they do not reach any altitude, and very often scarcely rise above the chimneys which pour them out, yet they often produce complete darkness. This is never seen in day-time, as the result of a wet fog, when there cannot be a suspicion of fuel-smoke. Has a darkness ever been produced at mid-day on the Scotch moors or among the Irish bogs? Has it ever been seen on the great ocean between this and the Western Continent? Fogs there are, intense and deep; shutting out sight as far as distance is concerned, it may be even limiting vision to a few feet; but there is always a whiteness about it, quite different from the fog of a great town. A pocket lens will easily show that this whiteness is due to minute particles of water, capable themselves of transmitting light, but which transmission, whilst decomposing an individual ray, yet re-combines the elements into white light again, and when the particles are filtered out by means of pure cotton wool, are shown to be composed of water. Not so a large part of the particles which are found in the fogs of great towns; they consist, in great measure, of organic matter, capable of absorbing light, not transmitting it, and, when filtered out of air by means of cotton-wool, are black-looking matter, with oily particles of some hydrocarbon oil of a tarry consistence, which seems to envelope the atom of water which is with it. Sometimes the oily matter is in excess; sometimes it is the solid carbon which is more abundant. By long continued exposure of plates of moistened glass, some crystals of sulphate of ammonia may be obtained, and also occasionally other kinds of *débris*, but, on the whole, the sooty particles are largely in excess of everything else.

The other day I went down to Reading, by the Great Western Railway. At Croydon the air was clear, the sky bright, but it was cold. London itself was dull and somewhat foggy. After leaving Paddington, a dark bank of cloud, resting upon the earth and reaching to an elevation of some hundred feet, limited vision to within a few yards of the line on its left-hand, whilst on the right the view was uninterrupted as far as the landscape allowed. The bank followed a straight line; it did not follow the turns and windings of the river, as would have been the case if it had been due to water as a main cause. The wind during the morning had been quietly veering from north to east, and with it came the line of smoke as clearly marked as any cloud could be. That it was not due to Father Thames was clearly seen when, on another occasion, the wind changing to north, a similar dense cloud came with the change of wind, and hung over the Sydenham hills and the heights about Sutton and Banstead, whilst the valley of the Thames above London was comparatively

clear. I have often watched these changes of wind from different parts of the Surrey hills, and seen the Crystal Palace disappear from view, although, at the place at which I was stationed, the sun was shining brightly, and shortly before the eclipse of the palace took place, the sun's rays were reflected most brilliantly upon the glass of that building. These observations have been made when the thermometer has been somewhat falling, but the other conditions requisite for the production of fog have not been present in those parts of the country where fogs are usually found, and the soil, being gravel and chalk, cannot be accused of being fog producer.

In my own neighbourhood the densest fogs come from the north, and these consist of a dark pea-soup atmosphere, which renders our district most unsatisfactory, whilst it lasts, as a health resort. Similar conditions are sometimes to be met with in the most favoured places. I was at Brighton on last Lord Mayor's day. It was a beautiful day in the Weald district. The country looked lovely in the autumnal tints produced by decaying vegetation, brought out by a November sun. The north side of the South Downs were perfectly distinct in outline, without a trace of mist upon them. There was a lovely sunset as seen from the new pier; there was nothing to limit the sight seaward but the distant horizon. Not so in the town of Brighton itself. Just after sunset the lights on the north side of Regency-square could scarcely be seen from the Parade, whilst the lighted gas lamps were quite invisible at the northern ends of the streets which run at right angles with the King's-road. Yet the sky was clear, the stars shone brightly, and there was no reason for the heavy and murky atmosphere in London-super-Mare on that evening, beyond the smoky chimneys, the soot from which could be seen pouring down into the streets and squares of the place, and as these were at right angles with the wind, there was no easy escape. The wind was from the west; it freshened into a gale late in the evening, and cleared the smoke away. It is, however, a curious fact, that Brighton, which is a place beyond all others free from fogs, in the common acceptation of the term, suffers occasionally from coal-smoke and its consequences as much as any part of London, whenever there is a calm with the slightest possible amount of wind from the west. If the barometer is high, and the thermometer low, with a north wind, the setting sun is seen as a dull copper disk, which disappears from view long before it ought to be lost to sight; whilst if the wind blows on to the land from the sea, there is no interference with the beauty of the retiring orb of light. I have witnessed this phenomenon on several occasions, so that one may draw the inference that, with a still atmosphere, high barometer, and falling thermometer, with the wind from the west or north, there will be a murky cloud settling down upon the place at sunset, which, but for the sea shore, would soon render Brighton, as far as fog is concerned, little better than the East-end of London. How is this to be accounted for? I think that the 110,000 fires which are burning there, in a narrow band under the Downs, and which, as the shades of evening come upon the place, are thoroughly replenished with small

to dense volumes of smoke from almost innery, and produce this change in the cause is one which man produces in his own purposes, and which, therefore, he can remove.

It might be thought by some that smoke is only a minor evil at present, but there are other and irremovable evils. Smoke from coal is secondary only, and its removal would be useless. It is thought that we have only to put the Smoke Act in force and stop the discharge of the clouds of smoke from factory chimneys, to remedy the evil. But the main cause is in the marshes, and as far as the valley of the Thames is concerned, it is between its rise and its fall into the sea. I think that land drainage would remedy the evil, but others refer them to the clay soil which covers the London basin. The irremovable evil is not account for the darkness and as which, if such were primary parts of the cause, it would be felt most on the Scotch moors and fens, but which are in reality never found. One ever coughs up a quantity of matter like a decomposed leech when out of doors, or among the bogs of Ireland, but it has just come out of a coal-pit; one can be long in a real London smothered in Manchester fog, without expectorating a violently nasty bit of filth, which shows the cause upon its very surface. We should see the conditions most frequent in places likely to give rise to them, if water was the cause; but fogs, produced in such situations, are always white fogs, and cannot be mistaken for smoke-made fog. They may occur in London, or elsewhere; they do rise in London, and they do in all clay deltas, if the conditions are present which cause the descent of smoke, they add very much to the dangers of the culties of the occasion; but white fogs rise from the ground, and grow upwards, whilst smoke or yellow fogs come down. White fogs are bearable, if alone; they are not dangerous except in a very minor degree, which may be seen in the Welsh valleys, on the Yorkshire fens, and the lowlands by the sea.

Who think that an enforcement of the Act, as it now exists, would greatly remedy the evil, are not quite aware of the main cause of the mischief. There are no factories in London, there are very few at work in London, and yet some of the worst fogs I have witnessed have been on autumn Sunday mornings, between the hours of ten and two. The cause for Sunday fogs, is the fact that on Sunday the London poor, and a large part of the middle class, dine at home in the middle of the day, and at there is always a good fire prepared for the forenoon, by the almost simultaneous burning of loose Newcastle or other small coal, as a consequence of that simultaneous fire burning, there are dense volumes of smoke from every house fire in the metropolis, about the time which cooking commences, which slowly fills the air with some part or other of the district. It is a great part of the cooking is done on Sunday; but, on Sunday, it is in the morning, as a consequence, there is a capacity for more fog if the meteorological conditions

favour it, which is not found on any other day in the week. In Brighton, the simultaneous charging of fires occurs about sundown, and the greatest volume of smoke is visible soon after sunset, when the days are shortening and the air grows cold. In the metropolis it is at midday on Sunday that there is always, if the wind is trifling and the barometer high, in some parts of the forest of houses, a cloud of unconsumed carbon, which obstructs sunlight, and in the aggregate, produces as much evil as did the pestilence of former days. Sudden deaths from the rupture of blood-vessels in various parts of the body are not infrequent, and other illnesses are common, which, sooner or later, have a fatal termination, but which are not referred in the Registrar-General's reports to the real cause of the untimely event. The effects upon human beings are innumerable. The irritation set up in the eyes leads to much individual suffering, and a great aggregate loss, whilst similar effects upon an irritable mucous membrane causes pneumonia, bronchitis, asthma, and a host of maladies, both painful and weakening. The injury to the skin is not the least part of the mischief, blocking up the pores, and interfering with perspiration, doing for man, in a minor degree, that which produces a much greater loss, to plant life, in a pecuniary point of view, and which, in its effect, cannot be estimated. I lay great stress upon the Sunday development of fog, because it is very striking to those who observe it from the outer side of the great centre. I have done this for some years, and have marked the way in which the London pall has invaded my own district, producing now and then a necessity for gaslight at mid-day, when I have been dining with my family at a distance of ten miles from St. Paul's. I have gone up to London after that, leaving behind me a dense black cloud resting upon the earth, finding it less dense at New-cross, not much fog in the City itself, and the North of London has been comparatively clear. On these occasions the wind has been calm in the morning, and blowing slightly from the north towards mid-day, and I have been told that there had been a fog in London in the morning, but that it cleared off about the time at which it invaded our district. On these occasions the barometer has always been high. One day I went down to Greenwich when Croydon was enveloped in London fog. It was not one quarter so intense at Greenwich as at Croydon. On another visit it was slight at Croydon but intense at Greenwich. The wind in the first instance was north with a point to the east, in the second it was north-west by west. In both instances it is quite certain that the wind did not cross the Essex marshes or any other marsh land before it reached either of the places I have mentioned, but the fog had simply been brought from the forest of houses which constitutes the metropolis of Great Britain. My early impressions were that the main cause of London fogs was intimately connected with marsh or clay land, so no doubt wet fogs are increased by those districts which are yet undrained, notwithstanding the incubus of an easy money market. Observation, however, has told me that only a moiety of fog is due to this cause, and that that moiety is the least injurious part. I have seen the fog grow, as it

were, within the radius of houses, coming down upon the ground, not ascending from it, presenting its first indications in too close proximity to the chimney top to lead me to doubt as to the source. Those who always live within the radius of the producing cause are often unable to see the changes which take place within the influence of that radius, but which changes are distinctly visible to those outside.

If the Essex marshes were the greatest factors in the case, the fogs themselves, in their invasion of other districts, would always have a distinct reference to some part of the Thames delta. The invasion of the table-land about Croydon and the Surrey-hills is not traceable to that source. A north-east wind does not give us worse fogs than those we get from the north and west. Our darkest fogs come most distinctly from the north; never from the east or south or west. I can predict with certainty the presence of dense fogs in Bermondsey and the City without visiting those places. They are always bad on those spring mornings when with us the air is clear, the sun shining brightly, and not a cloud in the sky; there has been a morning frost, the wind being distinctly south, but moving very slowly; our season ticket-holders on the southern lines then know that, as soon as they get into the New-cross cutting on the Brighton line, they find a dense fog, which grows darker as they get to Bermondsey, and in the City the gas is necessary. A white and wet fog does not by itself ever produce a necessity for gas, but when the smoke comes down as the white fog rises, there is difficulty, danger, and darkness all around.

These fogs are perfectly free from any suspicion of mixture with air from the Essex marshes. The simple fact is, that the smoke shuts out the warmth of the morning sun, which is reflected back again from the cloud below the chimney-pots, instead of warming the earth. I have known, on several occasions, a complete change of wind take place towards the middle of the day, the course being from south to west, then to north-west, finally resting in the north. With that change the sun becomes obscured, and is only visible as a dull copper disc, a cold raw feeling pervades the place entirely banishing the genial air which had so delighted us in the early part of the day. The change has brought us London smoke and London air. The sun loses his beauty and his warmth much more effectually than when clouds of the proper kind obscure him. He only shows a dull, copper-looking disc, which is very conclusive as to the presence of particles of unconsumed carbon in the air. The copper-looking appearance is quite different to that which arises during its natural eclipse; it is somewhat like it, but it produces a much colder feeling in the air, and makes one feel positively miserable and wretched.

The moon also tells us very clearly when the air is loaded with fuel smoke; its colour is altered, its silvery appearance is lost. It is quite different to that appearance which it presents when simply obscured by light fleecy clouds, themselves a near approach to an ordinary fog.

I have a suggestion to make as to cause. I have not been able to prove the truth of the suggestion, for it requires electrical apparatus

which I do not possess, but it appears to me capable of explaining the development of smoke fogs. Diffused electrical charges, concentrated over a small area, must be taking place in large cities from chemical acts, from the various manufacturing agents always at work, from magnetic developments consequent upon the close proximity of 3,000,000 people, probably as many animals, and, in winter time, certainly as many fires. This electrical development may be suddenly manifested in one direction at one time, in another direction on another occasion. Is it not possible that it may produce those atmospheric calms which occasionally precede local thunderstorms over our great towns? Is it not possible that the 3,500,000 fires which are sometimes lighted in the metropolitan area, and which cause a rush of hot air upwards, being positively electrified, may have a repulsive action upon the unconsumed carbon, in a negative state, and cause its rapid descent towards the earth, but to which it is not attracted? This might account for the reason why these fogs arise when the barometer is high rather than when it is low. The surface of the earth is colder than the upper regions of the air, and that coldness is not dissipated because the rays of the morning sun are reflected from it by the surface of the cloud, or are absorbed by the particles of carbon. One would expect the exceedingly light organic particles to go up with the heated air; there appears to be a repulsion between the particles of carbonic acid and the soot particles, for the air which contains excess of soot does not always contain excess of carbonic acid. There does not appear to be more carbonic acid in that which floats away from a chimney-top, than in that air which is collected at a corresponding resistance (40 feet), from the chimney, but which is comparatively free from smoke. It might be thought that the largest quantity of carbonic acid would be found close to the surface of the earth, from the greater specific gravity of its particles; but this is not so. There does not appear to be more carbonic acid close to the ground, than when the air has been collected twenty feet from the surface. With soot, the rule is contrary, the densest parts of stationary smoke fogs are nearest to the ground. This density shows itself in several ways. It obliterates light completely; but the most curious effect is the obliteration of sound, which prevents one from perceiving the approach of moving objects until they are close upon you, and moving vehicles suddenly appear like ghosts upon the scene; a noise upon the top of a building is heard much more distinctly than one near the ground. On the September Sunday to which I have already alluded, the noise from the traffic in Oxford-street was heard much more clearly than that from the middle of Park-lane, although I was in a part of Hyde-park much nearer to the latter than the former; at the same time, vehicles passing by the Wellington monument, where the fog was thickest, could not be heard at all.

It is reported that a so-called dry fog is sometimes observed in Belgium, where it is called *bug* or heat smoke, and is imputed to its right cause, viz., the combustion of peat grounds. If we could eliminate the particles of solid matter from the atmosphere, London and other large towns would be no worse as regards fog than other places, and

districts which, like Croydon (in reference to winds), are to the leeward of the great would not suffer in the way we do now from perpetual burning. There are some points connected with the subject which have been raised by scientific men, into which I need not enter. I committed myself to the theory that it is caused by the destructive distillation of and other fuel which causes the greater part of it; that it is not a "radiation fog" or a "rich mist," or simply a mist from the bosom of the Thames or the Essex marshes, or the sea-breeze. The literature which has been written regarding fogs is not extensive. My

Mr. Dines, read some practical remarks on dew, mist and fog, before the Meteorological Society, which is published in that Society's Journal for July, 1879, and which contains almost as much information upon the subject as is generally to be found. Mr. Dines also says, in a letter to me, "It is now pretty certain that the fog grows denser, and that just above the fog the air becomes (rather abruptly) several degrees warmer." He also adds, "at present I cannot make up my mind whether the roofs of houses, slate and iron like grass, and so cause mist and fog; are bad conductors, and, therefore ought to be covered with radiators." Mr. Dines also adds, "that, in my opinion, the water has nothing to do with the fog." In this opinion I concur. It is not that the immense combustion which takes place from fire and gas in London, naturally produces an immense quantity of watery vapour, which is precipitated at times from the chimney as fog. Whether this is so or not, will in no way interfere with my conclusions, for that fog may be a white fog, like the steam from a locomotive, if no carbon or hydro-carbon were discharged. Dr. Frankland is of opinion that the water becomes coated with volatile hydro-carbon, rather than with soot. This cannot be borne out as true on all occasions. The matter filtered from air, such as that of September 26, contained more solid carbon than volatile oil, as a few experiments with cotton wool easily proved. The size of the particle of water in the mist or fog is of no consequence, because I contend that, if the destructive distillation of fuel, as now conducted in fire-grates, could be limited, the noisomeness of London fog would be done away with; and it is outside my point to take up your time with details. The radiation from roofs may be a determining point in changing the direction of a static current, and may, perhaps, produce static magnetic states in the air above our great cities, as compared with the mass of matter below, which is worthy of a thought. It may be a determining factor as to white fog or no white fog, but there is no actual result to be gained from considering the notion of some wise men ridiculed the notion that uncondensed carbon is the cause of a London fog, and write that the quantity of carbon in a cubic foot of air is so infinitesimal as to be almost negligible. Need I say that my engineer critic is fully not aware that a difference of only 200 parts in a million, or only one grain in 5,000, in the case of carbonic acid gas, and even a smaller difference in the case of oxygen, will make all the difference between a healthy and an unhealthy atmosphere, and on his own showing, the effect of

smoke in deteriorating the air is far greater than this. My critic convicts himself as being in the position he wishes to place me in, when he accuses me of ignorance of my subject.

Most elaborate tables have been prepared to show us the quantity of sunshine which Providence has bestowed upon us during the past year, and a good inference has been drawn, indicating that each hour of the sunshine has been worth "so much." Let me ask how much sunshine has fuel smoke deprived the Londoner of, during the past two or three years. How much sunshine has this country been deprived of, and how much has vegetation suffered from this cause. Let any one stand, as I have done this autumn, upon the Cumberland mountains on a fine day, note the position of the wind, and if it comes from one of our manufacturing districts, he will observe a haze which limits vision, and which an air filter will show to be due to organic matter, referable for its origin to the destructive distillation of coal and other fuel. I have watched the smoke from the Lancashire and Cumberland factories, finding its way across the sea, in a distinct cloud-like mass, which, impinging upon the distant hills, has shut out sun-light as effectually as if it were London fog. How much it interferes with vegetation is patent to every one; and one has only to walk through a field of cabbages, in the neighbourhood of London, when wearing a pair of white continuations, to get evidence enough to prove the truth of my proposition, without requiring philosophical instruments for the purpose. Is it not ridiculous for anyone to assert that this effect is a trifle? How little can such critics know of the economy of nature; how little can they appreciate the goodness of the Almighty, who has, in vegetation, given us a means whereby we may cause the removal of the natural impurities that must arise in air, viz., the carbonic acid and albumenoid ammonia, which must be produced where people most do congregate. We impede that vegetation by our carelessness or our cupidity, and that which might make our cities much more beautiful and much more healthy than they are, can scarcely get a footing in our midst. But it is not vegetation alone which suffers. As I have said before, the life of man himself is materially shortened, and much mischief results to him in various ways; not only man, but his own works are rendered less durable. The injury to works of art is manifest. The glass shades over the frescoes in the Houses of Parliament, the condition of the masonry of the houses themselves, the crumbling outer halls of Westminster Abbey, the roughness which has replaced the smoothness of works of art in the old Abbey, and even in St. Paul's Cathedral, all points to the presence of matter in our atmosphere which the chemist tells us to be sulphurous acid derived from coal. Then look at the hideous erections with which our houses, and especially our public buildings, are disfigured; smoke preventers, smoke curers, horrible contrivances put up in the higher regions, pretending to make the rooms below in a habitable state. It would be interesting to know how many architects have been consigned to lunatic asylums, in consequence of this incubus upon their architectural works. A survey of London from the top of one of the high buildings in its midst, is one of the most extraordinary spectacles which can be conceived.

Tubes of the most outlandish shape, and most peculiar construction, obtrude themselves everywhere, and can probably only be equalled by a similar state of things in the underground drains. The aim and object of these hideous excrescences, both above and below ground, would appear to be to make the atmosphere, subsoil and aerial, as unwholesome as possible.

There is an important point upon which men differ considerably, viz., are fogs worse now than they used to be in former times? Several correspondents have assured me that they are no worse now than in the early part of the century; but need we argue this point? Given a clear sky, a high barometer, a falling thermometer, with but little wind, and there is not any day in the whole year in which a dim atmosphere will not be found at sundown somewhere in or around London. Can any one assert that this has always been a feature of the metropolitan district? Dense fogs, no doubt, have at times always occurred, and are primeval; but there are no substantial facts to show that pea-soup fogs are so. They stick to the point of origin; they may invade other districts at a distance; but when London was only a tithe of its present magnitude, were scarcely perceptible ten miles away. This is borne out by a verse which Gilbert West put up in an harbour at West Wickham, a village four miles to the east of Croydon, and which I find in Garrow's "History of Croydon"—

"Not wrapt in smoky London's sulph'rous clouds,

And not far distant stands my rural cot;

Neither obnoxious to intruding crowds,

Nor for the good and friendly too remote.

And when too much repose brings on the spleen,

Or the gay city's idle pleasures cloy,

Swift as my changing wish, I change the scene,

And now the country, now the town enjoy."

This verse, put up a century ago, would hardly now apply; sulphurous clouds reach much further than West Wickham, and we in the suburbs cannot so easily escape from a nuisance even then recognised as peculiar to a great city.

Only a week ago, a veteran member of the Strand Board of Works is reported to have said that some fifty years since wax could be bleached at Hammer-smith and Shepherd's-bush, but that now wax-bleachers have to go much further away from London, before they can get sun-light sufficiently clear to effect their object; London smoke interferes effectually against the particular industry of wax-bleaching. Was there ever such a fog in South Kensington, before it became the dense suburb that it now is, as was seen there on the second of this month? I will, however, now leave the consideration of the cause, and try to suggest a remedy.

It is much easier to point to a nuisance than to get it removed; I always object to criticism, unless it shows a better way of doing things. I object to overthrow an institution, without being provided with something better to put into its place, even if that institution is a nuisance. The overthrow of the domain of fuel smoke might be purchased too dearly. There is something so endearing and so national about our domestic hearth, so captivating about the ability to poke a fire, that I should never expect to remove these comforts from our midst; neither is entire removal necessary. The ability to poke a fire is the one thing which preserves many a mind from downright insanity, and to take away the power would

consign many an unstable mind to a madhouse. The thing is not to be done, therefore, without due consideration. Thousands of fires, nay tens of thousands, would not produce a London fog, spread about, as they might be, over the 300 square miles which constitutes the metropolitan district. A few such fires would do harm, and if such fires, being a luxury, were made to assist in performing a duty towards those who could not afford the luxury, good might come out of evil; though I would not support the notion that it is right to do evil that good may come. The question is how are smoking chimneys to be got rid of. It is a process which the Society of Arts, with all its array of powerful names, will not be able to effect. An appeal must be made to the Legislature upon the point, and I suggest that the Society be foremost in making that appeal. Let us ask them to pass such laws as will help forward the object which we have in view, for public opinion, public spirit, and philanthropy will not alone be able to effect it.

I believe that a short Act would be sufficient. That if local authorities had the power to levy a tax upon every fire-place so constructed as not to consume its own smoke, the smoke nuisance would disappear in a very few years. They should have the power to use the proceeds of that tax in the purchase of the gas and water works of the district, and so enable local authorities to provide the capital necessary for the purchase of these works without having to add materially to the local rate. Gas, like water, has become a necessary of life; no large town can carry on its work in the world without gas. It is false political economy for dividends from gas and water to be paid out of the life-blood of the country. Its property should provide the capital for the purchase of such works. That capital should be sunk at once, and the consumers of both gas and water should only be called upon to pay the cost price of the product, with such other charges as might be sufficient for the maintenance of the works in an efficient state, and when extensions are required, the property requiring the extension should pay the cost.

The practical experience of large consumers tell us that gas even now can be produced in the neighbourhood of London at 1s. 6d. per 1,000 feet if the charges on capital account are kept out of the balance-sheet, and they publish the fact in their own accounts. I take it, therefore, that 2s. per 1,000 would cover the expense of production, distribution, and maintenance; and if gas was supplied at that price in London, it would soon find favour as a cooking and warming agent, and would greatly assist to extinguish the smoke fogs (provided means were taken at the same time to put an efficient law in force against some of the most notorious of the company offenders). There are, probably, 4,000,000 fire-places in the metropolitan district; an average tax of 20s. upon each of these, payable after two years' notice, would cause the removal of three-fourths of them, and the remaining million would provide a fund which would, for a time, go some way towards paying off principal and interest upon the purchase of the London companies' claims in their works. If three-fourths of the fires were deprived of their smoke, the atmosphere of London would be deprived of much of its noisomeness. This might be still further diminished by rendering it incumbent

pon those who continued to have open fire-places burn only that coal which had been partially deprived of its smoke-producing qualities. Indeed, the sale of any other coal to private consumers might fairly be prohibited, and a considerable cess might be made in the coal dues upon that part of the coal which continued to be distributed within the metropolitan district when that coal was intended for consumption in open grates. These charges would, in a few years, remove between twentieths of the noxious matter which is now discharged into the atmosphere of the metropolitan district. It is probable that the production of a fog is something like the production of a frost. The temperature must fall below  $32^{\circ}$  before a frost begins at all. If the temperature is high, the reduction for a degree or two of no consequence. It is only when near to the freezing point that it becomes important regarding the production of ice. So it is also probable that, to produce fog, there must be a concurrent smoke from a certain number of chimneys within a given area, and if that number not reached, there will be no fog, even when meteorological conditions are such as may favour its production.

My proposition will be met by innumerable objections; all great social changes are so met. It is only by answering those objections, or showing them to be unsound, that real progress will be made.

First, then, as to gas fires, which I suggest as alternatives for open fire-places. I am told that they are injurious to health, that they are comfortable, that they make the air of the room so dry, that they smell offensively, and that the heavy gases which are formed at the base of the fire-place will find their way into the room. These are air arguments against bad workmanship, but are not sound as against gas fires. I have had a gas fire for some years in my consulting-rooms and library, and no one, at first sight, can know it from an ordinary coal fire. It never smells, and warms a large room thoroughly; there is no dust, and no work for the housemaid to do, and no destruction of books and papers from dirt. But I must not poke it, and I must not burn rubbish upon it. These are, next to its cost, its only disadvantages. A gas fire cannot dry the air of a room to a greater degree than any other fire. If a smell comes from it, the fault is in the work or the stove construction, and would happen at the same place with any other material. If I had gas in all my rooms, I could do with one servant less in my household. Chimney sweeps, who are now necessary adjuncts to every house, would find their occupation gone, and the mischief which soot and dust produces in every house would not arise. This would effect an enormous saving in our domestic outlay, and our domestic works of art would last much longer than they do under our present régime. Common grates need not be removed, gas fires can be fitted to any ordinary grates, and the only expense need be the cost of laying on the gas. I shall be told that it will be quite impossible for the poor to do this. It is not a thing which the poor should be called upon to do. The tax upon open fire-places should fall upon the landlord, and in the case of weekly tenements, the landlord should collect the charge for gas when he collects his rent. If the rent is not paid, he should have the remedy in his own

hands, by at once cutting off the gas supply. I am so satisfied of the power of our stove manufacturers to meet this point, by constructing stoves which should give a maximum amount of heat with a minimum amount of gas consumed, that I should hail the change as one giving an immense boon to our labouring population, by providing them with warmth without waste, and taking from them that tremendous source of dirt which smoke produces among them, and which manifests itself upon the faces and clothes of the children of our poor population. The pocket saving would not be the least part of the work, for no one can watch the waste which the poor man has to suffer in his efforts to make a little fire to burn up, without feeling that the change would be very much to his interests. Whilst, as far as the gas rental is concerned, the poor should be called upon to pay the average weekly cost in advance, just as they now have to pay for the coal before it is consumed. There would be no injustice or hardship in this, provided the law gave them a right to a drawback upon that which they did not consume. The enormous advantage of a gas fire in a sick room has only to be felt to be at once appreciated. There is no waking up the patient by having to poke the fire and put on coals; there is no sudden discovery that the fire has gone out whilst the wearied nurse has slept, at the moment, perhaps, when it was very important that the air of the room should not get chilled. Indeed, the advantages of being able perfectly to regulate the heat of the room in such cases is immense. Those who do not like a gas fire need not be obliged to have one; they may find a much cheaper substitute in the beautiful slow combustion stoves which are now very generally manufactured. I would especially refer to those of Mr. Doulton, at the Lambeth Potteries, and which are formed of fire-clay; I prefer these to those made of iron. The fire-clay radiates heat much better, without depriving the air of its health-giving qualities. No one can have compared the heat given out by a common fire-place, having a fire-brick back, with one with only an iron plate, without at once giving the palm to the fire-clay material. These stoves provide that nine-tenths of the heat produced by the fuel consumed shall be utilised in the apartment, and not sent up the chimney, as is now done from ordinary fires. These stoves are a great advance upon the ordinary iron stoves. The air is not altered in its character by coming into contact with hot metal. The stove is not a nuisance in its appearance, but may be made an imperishable work of art, which will bear ill-treatment, and only want washing when dirty, instead of paint or blacklead, which, when used, smells most abominably all over the house. I think it very important that the use of fire-clay should supersede that of iron. Coal, as now burnt, is burnt to waste; in all other fire-places, and in great numbers of ordinary stoves, the heat generated is dissipated in the air above our houses. There was a scare some time ago regarding the exhaustion of our coal-fields. The bare possibility of such a thing should lead the Legislature earnestly to consider the fact that not more than one-sixth of the coal, now consumed, is usefully employed, and its waste might very fairly be prevented.

There is also another question which this change would solve, and which would be of immense advantage to the local authorities of the metropolis. Tens of thousands of loads of ashes which now block the dust-bins, and are such an incubus to the Vestries, would then have no comparative existence. The organic matter which the Vestries would have to collect and to dispose of could be easily dealt with by fire. There would be other changes besides a purer air; it would give relief to the traffic of our streets by taking out of them the long array of coal waggons and dust-carts which now delay other and more important traffic; and the Vestries would find a solution to a question which at this moment is exercising their ingenuity to a very serious extent, without their being able to find a solution for their difficulty.

Then look at the architectural advantage in an æsthetical point of view. Imagine London without those productions called smoke preventers, and those hideous chimney stacks which spoil all proportion. Think of the incubus which would be removed from the architect's mind when he felt satisfied that the chimney doctor would not be required for the purpose of spoiling the appearance of his edifice.

It will be urged that taxes of the kind proposed, are all wrong—that it is going back to a tax which, once upon a time, produced rebellion in our land. Then the window tax is instanced as one which had to be given up. But the window tax was quite the antipodes to the smoke tax; one was the means whereby light and air was shut out, the other is not for the purpose of raising a revenue, but to put down a nuisance, and to lead to the purification of the air. I propose a tax in preference to a penalty. Penalties require persons to enforce them. The infliction of a penalty is invidious, when it has to be enforced against our neighbours and our equals, and when it is possible that the magistrate himself may be an offender against the law. There are many difficulties which are shown in those places, in which the smoke nuisance from manufacturing premises is even now allowed to continue, in spite of the Smoke Act—and why? Because the members elected to serve on Local Boards are themselves offenders against the Act; and the magistrates who have to enforce the law, are themselves law-breakers in this very matter, it follows that in places like Warrington, Wigan, and Manchester, the law is defied and penalties not enforced. This would be even more certain to follow if there were to be penalties for smoking chimneys. But make it a heavy tax, which all who do not comply with the law must pay, and the difficulty vanishes, as far as the money question is concerned.

The power to proceed against the manufacturing offender should be placed in the hands of a public prosecutor, and should not be left with the local authority who, as at Bow and Stratford, allow the law to be a dead letter, because if enforced, it would be upon the members of the local authority or their friends that it would have to be levied.

Any law for the reduction of the smoke nuisance would only be partly effectual which did not touch most heavily the greatest offenders, viz., the railway and steam-boat companies. One great reason for the greater intensity of fogs

in the present day is the fact that, as soon as a white fog settles down upon the metropolis, if it be attended by a falling barometer, thousands of cages are brought out all along the railway lines, and are banked up with small coal and breeze instead of coke, and which give out dense clouds of smoke. They tend to render traffic on the railway more difficult than it is elsewhere. These cages contain fires ostensibly for the purpose of warming the watchers who signal the trains. I say ostensibly, but that they do not effect their object is but too evident from the appearance of the poor men themselves. If, instead of providing such fires, the companies would provide the men with proper dresses, such as arctic voyagers wear, there would then be no occasion for the fires, and the men would be much more comfortable. In addition to this change, which humanity ought to dictate, it should be a public prosecutor's duty to compel companies to run engines which really consume their own smoke, and the dense volumes of black smoke from steamers on the Thames should be ruthlessly put down.

I know that my proposals will raise up a host of antagonists, especially among those who believe that they are owners of a patent or a fuel which, if Parliament would but compel the people to use it, would stop the nuisance. I think my proposal will promote their interest much more than any legislation in the direction they contemplate. A still more powerful opposition will arise from those who believe that they have vested rights in the perpetuation of the nuisance, not the least of which ought to come from the sweeps, an honest and industrious set of men, who would suffer most from the change; but the most powerful opposition would be from those who are profiting by the mischief, and making immense sums of money by the perpetuation of the nuisance. I am in doubt as to the best mode of proceeding; but this meeting will, I feel sure, endorse Mr. Micawber's opinion that "something must be done," without following that gentleman's example, but will advise that action be taken of a determined character. I would propose that the Home Secretary be approached, and that he be urged to procure the appointment of a Royal Commission to inquire into the whole subject. I have put before you my own views under three heads. They are—

#### 1. The causes of the intensity of town fogs.

I refer these to fuel smoke, which I contend to be an unnecessary adjunct to fire. That the method now used for warming our houses and cooking our food is wasteful in the extreme, and five-sixths at least of the developed heat is lost, and much of the fuel passes away unconsumed.

#### 2. The means which should be adopted to prevent these causes continuing in operation.

These means should be the production of gas at a cheap rate, so that it might be used for cooking, and in many cases for heating purposes also.

In reference to this point, I would observe that the use of gas for lighting purposes will pass away; it would be to the interest of the companies that heating power should be developed in the gas manufactures rather than lighting, and that it would be promoting the object we have in view if the sale of coal was prohibited in the metropolitan district, unless it had been previously deprived of its smoke-producing

That a tax upon fire-places not so cons- as to consume their own smoke would be object, which might also be assisted by a tax upon the untreated coal when sold in consumption in the metropolis. That each of these taxes should be used by the authority in extinguishing the present companies who manufacture gas and dis- vater. That the use of closed stoves should be urged as much as possible. That the steps which should be taken to pro- ceed objects would be best met by urging a Government the propriety of appointing a Commission to inquire into the whole and who should formulate the grounds on which legislation should be established, and the way for the introduction of a Bill into Parliament for the purpose.

### DISCUSSION.

The Chairman observed that Dr. Carpenter, in his paper, had noticed the existence of fogs in the But for the existence of such fogs in the Legis- in 1855, the metropolis would have been, in fact, relieved of the evils in question some years ago if clear measures had been prepared, which, in fact, must be resorted to now. He (the Chairman) stated, as one of the first incidents of his sanitary work, a local officer pointing out to him from an estate, in a rural district, a white fog which at low tide was spread evenly like a blanket over a marsh. That regular fog, the medical officer covered the bulk of his patients. Outside of the estate he had scarcely any but midwifery cases and a few. Such fogs are always lowered and frequently cleared entirely by the process of land drainage. The drainage of the sewer gases and of soot to the rural district would compound a fog of much the same primary character as the London fogs. A great part of the uncovered site of London was supersaturated with sewage waste water, amounting to forty or seventy millions of gallons daily. The death-rate from attacks of zymotic disease in the lower levels of the metropolis would be double the rate of attacks in the higher levels, which, however, were subject to the ascending miasma from the lower levels, as well as from inter- mediate flat tables. Then there were the stagnant sur- face of one thousand miles of sewer deposits, as well as of bad house-drains. The whole of this contamination would have been removed by the option of the self-cleansing system of im- proved sewers proposed, and removed at half the cost of the stagnant system. The effect to be obtained by the substitution of a self-cleansing system would be the same as that produced by heavy storms, when the unusual freshness of the air they breathed, here was, outside the covered areas, extensive areas of marshy land, so named, the Essex and other areas, which would be benefited in increased pro- portion by subsoil drainage. Fogs occurred in the district amount when the wind was easterly; and on occasions, marsh diseases and ague were more common (for the most part in the portions contiguous to the marshes but extending to the western parts of the metropolis) than was supposed, as deaths, arising in the marsh diseases, where not entered in the registers. For the reduction of these diseases arising from supersaturated subsoils, the method of soil drainage, by pumping for the whole of the metropolitan area, the lower tracts in the uncovered area, and the subsoil drainage of the continuous uncovered area, the eastern and

other low-lying marshy land was prepared for that land at a remunerative expense, and for the inside or covered area at an expense of about 9d. per annum per house for the extra pumping, the effect of which would be the same as if the whole site were elevated a number of feet. The engineering principle of the arrangement was similar to those in the Fen districts for sending the rainfall to the rivers, one sanitary effect of which was that where pounds of bark were formerly used, only ounces were now used against ague. They had no experience of fogs in dry weather or from soot alone, without moisture or damp, such as arose from supersaturated soils, an evil they had always with them. Richmond-park was once the seat of heavy fogs, from which it has been almost entirely relieved by drainage, and the health of the deer and cattle improved, and it would probably be relieved entirely, as also the other parks and open uncovered spaces, by a better system and work. The subsoil drainage of the site of Birkenhead had cleared away fogs there. At Liverpool, the reduction of damp, by the reduction of the supersaturation, by the reduction of the waste of water, is reported to have caused a material reduction of the death-rate. The measure for the removal of stagnant sewage and its evaporation, and sending the sewage, not to the river, but to the land, had been started by the German engineers, and was now in the course of successful application there. The next evil of which an examination had been entered into, but not carried very far, was the smoke nuisance. For this, the use of smokeless coal, such as anthracite coal, was indicated, and on this topic the National Health Society had entered into a very promising course of inquiry, for which public support was needed. The Society of Arts had conducted an inquiry some time ago for the award of a prize for new inventions of grates and ranges that consumed the least quantity of fuel; but it was found that the new inventions did not excel, and were often the same as old inventions which had never got into use; and they never got into extensive use at all, on account of the first expense of change. The compulsory measure advocated by Dr. Carpenter would be available as a motive for the purpose, but the Board of Health contemplated also the use of half-coked coal, which would have the quality of anthracite. They also contemplated the extended use of coal gas in houses for warming as well as cooking and lighting. This extension appeared to turn mainly on the reduction of the price of gas, and that by putting the supplies upon a public footing and public arrangements. The first obstruction to the extension of the use of gas apparatus, as well as new fire-places, was the selection and the cost of the apparatus for distribution into houses. For remedy, it was contemplated that the company, or the lighting authority, should substitute the apparatus and keep it in good action, for a rent, as was now done with gas meters, and, indeed, as had been done with great success in a provincial town for the whole apparatus. Instead of having to pay at once some six pounds, the occupier would only have to pay a rate of some six shillings a year, with the security of attention to the fittings. Measures could not be expected to be adopted without examination and preparation, and for examination and preparation a competent service must be appointed, provisionally, for the examination of the subject, which was more complex than might be supposed. But then it had to be determined what apparatus was the cheapest and the best. The chief gas company in London, for its own interest in the extension of the consumption of gas, would have promoted competition for the cheapest apparatus, but it was decided by the Board of Trade that they had no power to do so, and the Metropolitan Board of Works opposed their obtaining power. Power was also required to get the cheapest apparatus for cooking, and for warming and ventilating by gas, for warming by an apparatus that warms the pure air

which it pumps in, and removes the vitiated air. One thing is attendant on the introduction of gas into houses for warming—that there is a considerable reduction of the smoke, dust, and dirt within the house. One thing has not hitherto been attended to on this subject of the smoke nuisance, and that is, the washing bill, which may be reduced, under good conditions as to smoke consumption, and the washing bill for the metropolis may now be estimated at full six millions and a-half. Dr. Carpenter had talked of the amendments proposed, as requiring much money. Now when fully examined, it would be found that the measures, which were sound in sanitary principle, really saved money. If he (the Chairman) were now in office, with full executive powers, he would set aside his own particular measures, and the measures proposed by others of his time, and re-examine them, and prosecute the subject *de novo*. He agreed entirely with Dr. Carpenter's conclusion for the appointment of a Commission to examine the whole question, as the speediest means of obtaining efficient relief.

Mr. Robert Rawlinson, C.B., had listened with great pleasure to Dr. Carpenter's address, and agreed in the main with his proposals. He had explained the existence of fog in a very lucid manner. It did not always arise from vapour, but it did frequently, and in those cases, the removal of subsoil water by drainage would often abolish it. They knew that large areas were often covered with dense fogs in autumn and winter, but when these were drained, the fogs diminished. Every cubic foot of water removed, which would otherwise evaporate as vapour, allowed as much heat to remain as would raise two million cubic feet of air 1°; and when land was effectually drained it had been asserted that the mean temperature was permanently raised from 4° to 6°, and consequently it was equivalent to removing it a certain amount farther south. Dr. Carpenter had mentioned a fact which he also had often noted, though he had not understood it, viz., that fogs commenced with a very high barometer. One would have imagined that smoke would rise more readily in a dense atmosphere than in a light one, but it was not so. As soon as he saw the barometer begin to rise in autumn and winter, he knew he must expect a thick atmosphere. He did not think the remedy proposed, of imposing taxation on fire-places, would be practicable. Englishmen were, very properly, irritable under taxation, and he thought the Legislature must find some other means of diminishing the consumption of coal and the production of smoke.

Mr. G. J. Symons, F.R.S., said this was the first time he had said anything about fogs, though he had studied their conditions for many years, having been all his life in a good position for such study. It was assumed that fogs were increasing, and were much worse than formerly, but he thought that was only another illustration of what was often found, that present evils always seemed bigger than past ones. We had just passed through half a dozen exceptionally wet years, and, consequently, the surface of the metropolis, which is yet undrained, had been in a wetter and colder condition than usual, and the result was to give an exceptional intensity to fog. He was quite prepared to say they had more fogs last year than usual, but as to their being very much worse, he doubted it. He would not occupy time by giving specimens of the fogs of bygone years, but he recollected some quite equal to anything we had had lately. Taking South Kensington for instance, he lived near there all the early part of his life, and his father went snipe shooting where Victoria Station now stood, and in that district, at that time, the fogs were quite as bad as they were now, though he was not prepared to say they were not whiter. There was no doubt that the carbon in the atmosphere did make the fog yellower, but he must leave it to medical men to settle how far that

carbon was really injurious. He was rather sorry to hear the reference made once or twice to the magnetic condition of the atmosphere, for there was a tendency, whenever we did not understand anything, to hook it on to either electricity or magnetism. He would suggest that when we did not know, it was better to acknowledge our ignorance at once. He was not by any means charmed with the suggestion of referring this question to a Royal Commission; he had, unfortunately, been a member of two or three deputations lately to different branches of the Government, and, really, if they were to take up all the questions which were brought before them, and which they were expected to settle off-hand, he pitied them. He feared the appointment of a Royal Commission was rather the way to get a thing shelved; you got a wonderful Blue-book, which hardly anyone read, and, as a rule, nothing was done. He agreed with the remarks about gas fires; but in connection with them he had one grievance, which he believed was common to all who used them. He was quite sure the gas companies did not consult their own interests in giving such a low pressure during the day-time, the consequence of which was that when you wanted a good gas fire you could not get it, though in the evening, when the room was warm, you had a very good one. There could hardly be two opinions as to the advisability of gas companies turning their attention to the supply of gas for heating instead of lighting purposes; and he was glad to find, when at Exeter recently, that the gas companies there were thoroughly alive to the importance of this matter. With regard to the relation of fogs to barometrical pressure, it was generally known to meteorologists that fogs were found in the time of an anticyclone, which meant a heaping up of the barometer, just as a cyclone meant a diminution of pressure. Of course London, like other places, got a greater prevalence of fog when it got a greater prevalence of a high barometer, and they had an anticyclone of that character last year, and it was accompanied also by a low temperature. You must have low temperature and high pressure to get fog, and still more, you must have a cold state of the ground. Mr. Rawlinson was perfectly right in laying stress on the question of drainage, because the drainage and consequent warming of soil must diminish the amount of fog upon it. He would suggest the possibility that the very large amount of ground which had been built over, paved and drained, and recovered from its natural state, must perhaps, to some extent, have tended to keep the amount of fog constant; because while, on the one hand, there was more smoke from the habitations, on the other hand, there was a smaller area of evaporating surface. The only other remark he would make was one, showing that London was not alone in its complaints as to the increased prevalence of fogs. The anticyclones of last year prevailed over the whole north-west of Europe, and he heard from a Parisian friend the other day, that of late years they had had a very remarkable development of fog in Paris. After a very careful investigation, the Parisians came to the conclusion that they had had it ever since the Prussians came there.

Sir Francis Knowles F.R.S., said this was a most important subject, affecting not only the pockets of the people, but their health and the length of their lives. He wished to support, as far as possible, the conclusions to which Dr. Carpenter had arrived. An ordinary coal fire was generally left to burn rather low, then the door was opened, letting in a fierce current of cold air, and the housemaid piled on a heap of coal, which left all the inmates of the room in the discomfort of a glacial period until it burned up. He had made some calculations as to the result of the coal consumption in London, which were as follows:—The annual consumption might be taken at about 8,000,000 tons, or a daily consumption of 22,000. The ammoniacal liquor from bituminous coal was about

per ton, and deducting 13 lbs. for ammonia, out 166 pounds of watery vapour per ton of 16½ gallons. In other words, there were 166 lbs. of ammoniacal liquor daily ejected into the sphere, with a due accompaniment of coal-tar &c. The injurious influence of this on the organs needed no proof, but prize cattle known under its influence. Turned into the watery vapour of this liquor amounted to 51,194,880 square feet, one-eighth inch in representing a most respectable daily rainfall; imputation did not show what was the cause he did not think anything would. The this ammoniacal liquor was most serious. Fields contained an enormous supply of nitro-sulphur, which, properly applied, would convert of England into a garden, and from a calca had made, he estimated that the ammonia on the combustion of coal in London alone was a production of six million quarters of coals. Extant to the whole country, would give some idea of this waste on our agricultural prosperity. Some ago he tried an experiment with carburetted from peat on red hematite ore, and, at the 10 hour and a quarter, when he drew the charge out, he found more charcoal at one side, and the carburetted hydrogen had reduced the almost to the condition of a metallic sponge. And how advantageous it would be partially to coal, employing the gas in this way, before it to London for use in fire-places. There are modes of avoiding the evil of fog, viz., hydrous coal, or anhydrous gas. In any burning apparatus which might be devised, suggest, lastly, that it would be desirable to some means for condensing and utilising the

gases thought the proper distinction to be kept was that between fogs and mists, the latter being of nature, and the former by man. Then it arose, was it possible to prevent London a great deal had been written in the papers on fog lately, and one correspondent had stated that more frequent now than they used to be in the shroud of Lord Holland's park than formerly, that park was not drained. Now, he disagreed, because the greater portion of the park was on a rise, and therefore drained naturally. The ground in the neighbourhood of Kensington had been so covered with mounds and roads that fogs there, and in the whole western suburbs, were nothing to what they were in recollection. Fogs existed all over Europe; collected about 30 years ago being in Paris, the densest fog he had ever seen prevailed for an week. Only last week he read in the Times that he, for several days, unable to get into Havre, out of the fog, and he had often been delayed and when coming up the English Channel by the same. He admitted the blackness of London did not think they were as bad as they used to be for the proposed remedies, he dissented entirely from Carpenter's conclusions. In the first place, the Secretary would laugh at them, if they went and proposed that he should put down fogs by a tax on fire-places, or by compelling people to use gas, whether they liked it or not. Gas was an as fuel at present for general use, for many years. In the first place, the mains would not be enough for the supply, and the companies would be to raise capital sufficient to relay the whole system; on the chance of the public using it when it came. He had had a gas-stove in his house for the years, but it was never used; and as for gas set of those who had tried them know that they gave was a minimum quantity. There was a great risk of smell, and danger from the

great difficulty in getting good gas-fitters. They had quite enough gas explosions at present to render it very undesirable that the risk should be further increased. With regard to cannel and anthracite coal, they had been tried in ordinary ranges for forty years, and were a complete failure, except in the case of a very large fire, and then it required to be lighted and supplemented with ordinary coal. Then they were asked to stop the smoke that came from locomotives and steamboats. If Mr. Bramwell were there, he would tell them, that any one who could devise a means of doing so, would make a million of money; but the ingenuity of man had not yet succeeded in bringing forward an invention which would answer the purpose, and therefore it was needless to approach the Government with any such proposition.

Mr. Bamber then exhibited and described the grate, with a solid dead plate instead of the under grating beneath, which had been invented by Dr. Siemens for burning coke, thus preventing smoke. The fire burned only in front, where the heat could radiate into the room, the heat being withdrawn from the back, where it was of no use. This was effected by means of a copper back, which conducted the heat to the under portion, and through a copper grill work, which heated the air passing up by means of a vertical passage in front of the copper grill work, and a horizontal passage below the dead plate, into the front of the fire, where was an iron gas tube pierced with holes inclining upwards at an angle of 45°. Through this the gas passed, and served to light the fire, formed of coke or a mixture of coke and anthracite, after which the gas was partially turned down, but still served to keep the fire cheerful. Another and cheaper form of stove, was made entirely of cast iron. The cost in fuel was about the same, or rather less than that of an ordinary coal fire. The last speaker had said it would be impossible to supply sufficient gas for general heating purposes, but with this arrangement only a small quantity was required, about 12 cubic feet the first hour, and six or seven per hour afterwards, for a room half the size of that hall. Coke was rather a drug with the gas companies, and this would enable them to get rid of it, so that he had no doubt they would be glad to take it up.

Mr. Mitchell said the discussion seemed to have wandered into all sorts of subjects except the one specially brought before them, which was the cause of London fog and the means of getting rid of it. He hoped before the discussion closed, a little more light would be thrown upon these important questions.

A Member asked the cost of Dr. Siemens's grate, which he had inspected and was much pleased with. The ordinary substance gas fire he considered a mistake.

Mr. Bamber, in reply, said that the cost in cast iron, was 25s.; in copper, about two guineas.

Mr. Tracey, having protested against the Society being made an advertising medium, said, according to his experience, London fogs were no more dense than when he first remembered them. Again, London smoke was anything but an unmitigated evil, for it greatly neutralised the noxious effluvia arising from our present system of drainage. After a heavy shower the air in London was purer than in the neighbourhood of a country house, where the smell of the drains was always very prominent at such times.

Mr. G. M. Shore, after complimenting Dr. Carpenter on his paper, read a letter he had received from Mr. Deacon, engineer, of Cardiff, praising a furnace of his (Mr. Shore's) invention, a model of which was on the table. By means of this apparatus, the principle of which was a down draught and hollow fire bars, he warmed his entire house and a large conservatory with a fire-place 13½ inches wide and 16 inches long.

Thorough ventilation without draught was easily obtained, and it could be adapted to coal mines, and prevent the sacrifice of human life.

Dr. Carpenter, in reply, said the discussion had been so discursive, that it was impossible to deal with the whole of it, and it was the less necessary to do so, as many of the points taken up were not strictly within the scope of the paper. The observations of Mr. Symons were very pertinent, and he agreed with him that the extension of the metropolis had reduced the amount of evaporation within the area. But the fogs which arise in connection with the moisture of the earth were not those which the meeting was convened to consider, as they were found everywhere. Great objections had been made to the proposal to put a tax on fire-places, as he had foreseen, and the appointment of a Royal Commission had also been objected to, but he still adhered to his opinion, that a subject of this difficulty would be better dealt with, in the quiet air of a committee-room of the House of Commons, than by any kind of discussion likely to take place in such an assembly as the present, where everyone had ideas of his own, not always based on scientific principles. Reference had been made by one speaker to coldness of the ground as a cause of fog, but he believed the soil of London was very much warmer than that of any other part of the British Empire, and it was possible that, instead of coldness, warmth might have something to do with it. He quite agreed with Mr. Symons that people often referred to magnetic influences when they were ignorant of a subject; he confessed his own ignorance, and he believed the majority of investigators were in a like position, though some might know much more about it than himself. He had, therefore, taken the liberty of introducing the reference to the magnetic state of the atmosphere as a thing worthy of consideration by those who were studying the subject. He hoped the suggestions he had thrown out would be the means of leading some of his hearers to think a little more about the subject than they had done hitherto, and to press it on the Legislature. He knew, from personal experience, and the records he had kept for many years, that fogs of this character were much more extensive, heavy, and frequent than they were 20 years ago, and extended to a greater distance from London.

On the motion of the Chairman, seconded by Mr. Higgins, a vote of thanks to Dr. Carpenter was passed.

#### CANTOR LECTURES.

Prof. A. H. Church, M.A., F.C.S., delivered the third lecture of his course of Cantor Lectures, on "Some Points of Contact between the Scientific and Artistic Aspects of Pottery and Porcelain," on Monday, 6th inst., in which he dealt with stone-ware, and other wares, glazed with salt.

#### THE PHONOPHONE.

In accordance with the notice given in last week's *Journal*, a selection of the more important diagrams used by Professor Bell in his paper are now published.

Figs. 1 and 2 show the form of selenium cell used by Werner Siemens; Fig. 1 shows the zig-zag

FIG. 1.

arrangement of the wires, and Fig. 2 the spi

FIG. 2.

Fig. 3 is the apparatus employed in annex

FIG. 3.

selenium cells by Professor Bell. The cell being plac

rior vessel, and surrounded by outer vessels containing oil, a suitable source of heat is applied below the whole arrangement. Fig. 4 represents the latest selenium cell, in which alternate plates of brass and selenium are placed on a central spindle, and held by rollers passing lengthways through the arrangement. The mica discs being slightly smaller than the discs, annular spaces are left, which can be

FIG. 5.

with selenium. Fig. 5 represents a cell as described in the focus of a parabolic

FIG. 6.

Fig. 6 shows one of the earlier forms of transmitter employed by Professor Bell, in which the diaphragm is caused to vibrate over a fixed grating, impulses produced by the voice impinging on a diaphragm, fixed to the movable grating. Fig. 7 shows the whole arrangement for sending and receiving. A beam of light is reflected on a mirror, the back of which the sender speaks. The rays reflected from this mirror pass through a lens, and are received at the distant station by the parabolic reflector, the selenium cell as its focus. Fig. 8 and 9 show

mirror for reflecting the light through the lens, *L*; *D* is the perforated disc; *C* is a lens, employed only when the apparatus is used to transmit signals, for which purpose the lever *S* becomes into play; *R* is the hearing tube, at the mouth of which can be placed any substance to be tested for its power of producing sound under the impact of an interrupted beam. Fig. 12 shows the sending arrangement for the articulating telephone. *M* is the mirror; *L* the lens; *D* the flexible mirror or diaphragm; *S* the lens through which the light passes to the distant station; *C* is the mouthpiece of the speaking-tube. The two pieces of apparatus illustrated by the perspective views were exhibited by Professor Bell during his lecture. The blocks, by which the last two illustrations are reproduced, have been kindly lent by the editor of *Engineering*.

### MEETINGS OF THE SOCIETY.

#### ORDINARY MEETING.

Wednesday evening, at eight o'clock:—

DECEMBER 15.—“The Use of Sound for Signals.” By E. PRICE EDWARDS, Secretary to the Deputy-Master of the Trinity-house. Dr. TYNDALL, F.R.S., will preside.

#### CANTOR LECTURES.

Monday Evenings, at eight o'clock. The First Course, on “Some Points of Contact between the Scientific and Artistic Aspects of Pottery and Porcelain.” Five Lectures, by Prof. A. H. CHURCH, M.A. Oxon., F.C.S.

LECTURE IV.—DECEMBER 18.

Soft paste porcelains, European and Oriental.

LECTURE V.—DECEMBER 20.

Hard paste porcelains, Chinese, Japanese, and European.

### MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 13TH. SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. A. H. Church, “Some Points of Contact between the Scientific and Artistic Aspects of Pottery and Porcelain.” (Lecture IV.)

Institute of Surveyors, 12, Great George-street, S.W., 8 p.m. A Discussion will be opened by Mr. Daniel Watson with a short paper, entitled “The Land Question in 1880.”

Royal Geographical, University of London, Burlington-gardens, W., 8½ p.m. Captain T. H. Holdich, “Geographical Results of the Afghan Campaign.”

British Architects, 2, Conduit-street, W., 8 p.m. Mr. John E. Price and Mr. F. G. Hilton Price, “Remains of Roman Buildings at Brading, Isle of Wight.”

Medical, 11, Chandos-street, W., 8½ p.m. London Institution, Finsbury-circus, E.C., 8 p.m. Mr. W. St. Chad Boswell, “The Kings of the Hittites—their Unburied Monuments and Civilisation.”

TUESDAY, DEC. 14TH. Civil Engineers, 26, Great George-street, Westminster, S.W., 8 p.m. Mr. T. Eyring, “The Different Modes of Erecting Iron Bridges.”

Medical and Chirurgical, 53, Berners-street, street, W., 8½ p.m.

Photographic, 51, Pall-mall East, S.W., 8 p.m. Anthropological Institute, 4, St. Martin's-place, 8 p.m.

Zoological, 11, Hanover-square, W., 8½ p.m. Secretary, “Additions to the Society's 3 during the month of November.” 2. Prof

Huxley, “The Application of the Laws of Evolution to the arrangement of the Vertebrata, and particularly of the Mammalia.” 3. Lieut.-Col. Godwin-Austen, “The Animal of *Ferussac's* Rizzo, from Mentone, concluding with a Classification of the above genus of Rizzo, and its Allies, by Neville.” 4. Mr. Arthur G. Butler, “A Second of Lepidoptera made in Formosa, by Mr. H. E. Royal Colonial, the Grosvenor Gallery Library, Bond-street, W., 8 p.m. Sir Richard Tennant, “Statistics of the Indian Empire.”

Royal Horticultural, South Kensington, S.W., 10 p.m. SOCIETY OF ARTS, Jc Adelphi, W.C., 8 p.m. Mr. E. Price Edwards, “Use of Sound for Signals.”

Meteorological, 25, Great George-street, S.W., 8 p.m. Rev. T. A. Preston, “Report on the Ph Observations for 1880.” 2. Mr. G. M. Whip

Variations of Relative Humidity and the Dryness of the Air, with changes of Pressure at the Kew Observatory.” 3. M. Whipple, “The relative frequency of given the Barometer readings at the Kew Observatory the ten years, 1870-79.”

Geological, Burlington-house, W., 8 p.m. 1. Arthur Phillips, “The Constitution and 1 Grits and Sandstones.” 2. Prof. P. Martini, “The Coralliferous Series of Sicily, and its with the last Upheaval of Himalayas.” Etheridge, “A new Species of *Trigonia* from beak Beds of the Vale of Wardour.” With the strata by the Rev. W. R. Andrews.

Bankers' Institute (in the Theatre of the London, Finsbury-circus, E.C.), 6 p.m. M. William Burnett, “The effect of the Devel Banking Facilities upon the Circulation of the Including (for the purposes of this Inquiry) term “Circulation,” Bank Notes, Country Bank Cheques and Bills. Being the prize essay for 1 year.

THURSDAY, DEC. 16TH. National Indian Association House of the Society of Arts, 8 p.m. 8 Temple, “The Effect of Western Education on the Natives of India.”

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. M. Darwin, “The Theory of the Growth of 4 illustrated by observations on the Bramble.

Col. E. Godwin Austen, “The Genus *Durges* Anatomy.” 3. Mr. Francis Darwin, “The which Leaves place themselves at Right Angles Direction of Incident Light.” 4. Mr. Wm. “A Revision of the Genus *Viburnum*.”

Chemical, Burlington-house, W., 8 p.m. 1. M. “The Estimation of Nitrogen by Combustion Nitro Compounds.” 2. Dr. H. E. Armstrong, “Naphthalene Derivatives.” 3. Dr. H. E. “Some Hydrocarbons Present in Resin Spirit London Institution, Finsbury-circus, E.C., 7 Oliver J. Lodge, “The Relation between and Light.”

Royal Historical, 22, Albemarle-street, W., 8½ p.m. Numismatic, 4, St. Martin's-place, W., 7 p.m. Philosophical Club, Willis's-rooms, St. James 6½ p.m.

FRIDAY, DEC. 17TH. Philological, University College, 7

# L OF THE SOCIETY OF ARTS.

No. 1,465. Vol. XXIX.

DAY, DECEMBER 17, 1880.

*Memos for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W. O.*

## NOTICES.

### ART-WORKMANSHIP.

#### I.

Society's Medals in Gold, Silver, and  
and Certificates of Merit, will be awarded  
mens of Fine Art applied to Industry,  
in 1881, by manufacturers, designers,  
men, or possessors of such works.

#### II.

Works may consist of illustrations of any or  
following processes, in combination or

ing in marble, stone, or wood.  
rusedé work in any metal.  
rured work in iron, brass, or copper.  
ing in ivory.  
sing in bronze.  
ing and engraving on metal—Niello work.  
nel painting on copper or gold.  
ting and modelling in pottery.  
rative painting.  
rs in wood (marquetry or buhl), ivory, or

so cutting.  
raving on glass.  
l mosaics.  
engraving.  
sinking.  
s-blowing.  
biding and leather work.  
roidery.

#### III.

Works the name of the designer and art-  
must be affixed. Further detailed rules  
ned later.

#### IV.

anged with the Council of the Royal  
all, that the place of exhibition for the  
ntioned works will be at the Royal Albert  
e time for sending in the works will be  
hereafter.

#### V.

ove regulations are issued subject to  
on.

### JUVENILE LECTURES.

The usual short course of lectures, adapted for  
a juvenile audience, will be given by Mr. G. J.  
Romanes, F.R.S., on "Animal Intelligence."

The dates for the lectures will be Wednesday,  
29th December, and Wednesday, 5th January.

The lectures will commence at seven o'clock.  
As in former years, admission will be by ticket  
only, and no member can be admitted without a  
ticket. A sufficient number of tickets to fill the  
room will be issued to members in the order in  
which applications are received, and the issue  
will then be discontinued. Subject to these con-  
ditions, each member is entitled to a ticket admit-  
ting two children and one adult. All members  
who require tickets should apply at once, as the  
greater part of the tickets are now disposed of.

### CANTOR LECTURES.

The fourth lecture of the first course was delivered  
on Monday, 13th inst., by Prof. A. H. Church,  
M.A., F.C.S., on "Some Points of Contact between  
the Scientific and Artistic Aspects of Pottery and  
Porcelain." The lecturer dealt with soft paste  
porcelains, European and Oriental.

### MUSICAL EDUCATION COMMITTEE.

A meeting of the Committee was held on Wed-  
nesday, 8th inst. Present—Sir Henry Cole, K.C.B.,  
Vice-President of the Society (in the chair), Mr.  
Alan S. Cole, the Rev. Thomas Helmore, the Rev.  
Newton Price, Mr. James Thomson, and Mr. E. C.  
Tufnell, with Mr. H. T. Wood (secretary). A  
meeting was also held on Wednesday, 15th  
inst. Present—Sir Henry Cole (in the chair),  
Lord Alfred S. Churchill, Mr. Alan S. Cole, Rev.  
J. P. Faunthorpe, Mr. J. Thomson, and Mr. E. C.  
Tufnell, with Mr. H. T. Wood (secretary).

### PRACTICAL EXAMINATIONS IN VOCAL AND INSTRUMENTAL MUSIC.

The next Examination in London will be held  
at the Society's House during the week com-  
mencing 10th of January, 1881.

The Examination will be held at three periods  
—morning, afternoon, and evening—viz., from  
10 to 1, 2 to 5, and 7 to 10 o'clock on each day  
of Examination. Candidates may select either  
of these periods, but, the number of candidates  
in these Examinations being large, no special  
day or hour can be arranged for. The numbers

will therefore be arranged in order of application. The Examination for the Organ and Harmonium will be held in the evening only, and special arrangements will be made according to the number of applications. No alteration can possibly be made in this arrangement.

The fee is 10s. for the Honours (including both vocal and instrumental Examination), and 5s. for the First or Second Class (vocal or instrumental) Examination. If vocal as well as instrumental music, or two separate instruments, be taken by the same candidate for the First or Second Class Certificate, a fee of 7s. 6d. must be paid. Candidates should send the fee in stamps, or P.O.O. payable to H. T. Wood at the Head Office. As soon as the arrangements are completed, a numbered card will be forwarded, notifying the day and hour at which the candidate should attend, and the production of this card will admit to the Examination. The candidate will be known to the Examiner by this number only.

Candidates must also send a written certificate from some person qualified to give an opinion, to the effect that they have a reasonable chance of passing. Candidates who have already attended these examinations need not again comply with this regulation, but must state the fact.

At the conclusion of the Examination of candidates for the First or Second Class Certificates, the Examiner will record the result, with the marks in each section, on the back of the card, and hand the same to the candidate. The examination of the worked papers in the Honours Grade will necessitate some delay, but the result of this Examination will be conveyed to the candidates in due course.

The Certificates will be prepared as soon as possible after the Examinations, and can be had upon application at the House of the Society of Arts, on or after 1st March, 1881, on presentation of the numbered card. Certificates cannot be forwarded.

The Council will provide a grand piano, harmonium, and an organ. Any other instruments must be brought by the candidates. The services of an accompanist will be obtained by the Society when candidates for singing are to be examined; candidates will, however, be permitted to bring their own accompanist.

The Examination for the First or Second Grade Certificates will occupy about a quarter of an hour. Three hours and a half will be allowed for the Examination for Honours, during which time the candidates will have to undergo the *viva-voce* and the practical examination.

No Certificate will be granted to any candidate for Honours who does not obtain a First Class in

the practical portion of the Examination, vocal or instrumental. Candidates holding of such Certificates, obtained in a former need not again undergo this portion of the Examination, but should bring their Certificate for Examiner's inspection. In such cases three and a quarter only will be allowed to the candidate.

The Examination of each candidate will be private; no one but the Examiner and accompanist being present, unless it be a member of the Society of Arts' Committee. Names of candidates will be published.

Particulars will be forwarded on application to the Secretary, Society of Arts, John's Adelphi. No names can be received after Dec., 1880.

## PROCEEDINGS OF THE SOCIETY

### FIFTH ORDINARY MEETING.

Wednesday, December 15th, 1880; Prof. TYNDALL, LL.D., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Andrew, Capt. C. W., 286, Kennington-park S.E.  
Bayliss, Samuel, 5, Victoria-street, Westminster  
Browne, Miss Annie Leigh, 53, Porchester-terrace, Johore, The Maharaja of, Singapore.  
Keymer, H. J. C., Marine-cottage, Gorleston-on-sea, Great Yarmouth.  
Reid, Arthur G., M.D., 24, Montague-street, W.  
Rigg, Arthur, 71, Warrington-crescent, Maidenhead.  
Taylor, George Noble, 3, Clarendon-place, Hyde-park.  
Wiseman, William Perival, Cumberland-house, Pennard, Glastonbury.  
Wragge, Clement Lindley, F.R.G.S., Farley Headle, Staffordshire, and Adelaide, South Australia.

The following candidates were balloted for and duly elected members of the Society:—

Begley, Mrs., 26, St. Peter's-square, Hammersmith.  
Fall, Thomas, 9 and 10, Baker-street, Portman-square.  
Fisher, Thomas, Church Entry, 75, Carter-lane.  
Horsman, Godfrey Charles, 22, King-street, Portman-square, W.  
Macaulay, Lieut.-Colonel George William, 43, Cavendish-square, W.  
Stubs, Peter, Statham-lodge, Warrington.  
Symmons, Edmund, Eagle-house, Hermon-hill, Warrington.  
Walker, Robert, J.P., Kidwells park, Maidenhead.  
Waterhouse, Sebastian, 37, Catherine street, Liverpool.  
Willans, William Henry, 23, Holland-park, W.

The paper read was on—

### SIGNALLING BY MEANS OF SOUND

By E. Price-Edwards.

In a recent trial it was argued that the mission of verbal sounds, i.e., of the

ed by articulate speech, should properly be d as signalling, but in connection with ervations which I shall offer to you this ; I prefer to accept the view of the learned on the other side, and to avail myself retort to the effect that, although my are in a sense transmitted to distant in this room, yet it would be an obvious lication of terms to say I was signalling e hearers. I think it necessary to make eliminary observation, because it is beyond urpose on this occasion to deal with ethods of conveying oral sounds which een so marvellously developed during the w years. The value to mankind of these hing discoveries cannot yet be fully appre- l. We are evidently on the threshold of changes, as regards means of carrying es; the steam locomotive, the penny post, e telegraph system itself, are threatened by ssibility of other more simple and direct ls being brought into practical operation, by of the telephone, the phonograph, the hone, and last, but by no means least, the hone, of which so brilliant a description was y given in this room by its talented dis- r.

these are not the instruments which minister practice of signalling, in the sense in which e to place it before you.

gnal is defined as a sign which has been upon to give notice of some occurrence, nd, or warning, to a person or persons at a e. The necessity for such means of con- intimations is too obvious to be dwelt upon. hardly recall to you the system of signalling con fires, which was so extensively in use in days; nor need I remind you that those ethods of ancient times have, in the process e, been generally superseded by simpler and ffective means. The splendid lighthouses coast, which convey guiding and warning s to the mariner; the coloured and other used for vessels at sea, and also for railway es; flashing signals, employed for com- ating between H.M. ships at night, and for purposes, are all suggestive of ancient prac- although more elaborate and perfect, and to modern requirements.

gs, again, have for centuries been used as ms and signals for the conveyance of es across intervening spaces. For military es they continue to be used, and for service hey have been so effectively utilised that now exists an international code, generally ed by all maritime nations, which permits ration to be carried on between ships of all ies, the combinations of eighteen flags and pennants being the signals whereby messages between mariners who do not even under- each other's language.

semaphore was once much used for military ling, but it is now almost entirely employed mecton with the railway service.

storm warnings, drum and cone shapes are d at prominent points on the coast, to indi- the approach of bad weather.

d I may allude to the valuable invention of eliograph, or sun-flashing mirror, which red such conspicuous service in the late wars

in Afghanistan and South Africa, by which signals can be flashed across an intervening space of from 50 to 100 miles.

Finally, signals of distress are made on board ship by the firing of rockets, and by flames on the deck.

It will be observed that the examples of signalling to which I have alluded are those which appeal to the sense of sight only. Signals, being intended for human purposes, are, of course, dependent upon human perceptions for their comprehension. Sight, as we have seen, is made available. I do not think any definite system has been developed by which signals can be transmitted through the medium of taste or touch; nor has science yet indicated any method of utilising the sense of smell for the conveyance of definite messages, although, in the vicinity of foul places and decomposing refuse, odoriferous signals are generally wafted abroad, plainly indicating the presence of germ-laden gases, and silently bidding us beware.

But the necessity for transmitting signals has been found to exist at times when sight is unavailing, and then the sense of hearing naturally suggested itself as the perception which should be appealed to.

Thus we arrive at the branch of the subject which I have ventured to bring under the notice of the members of the Society of Arts this evening; and I think it proper to say, that in preparing this paper, I have sought rather to make it a record of facts than anything like a speculative inquiry, and have encouraged myself to hope that my efforts may possibly be the means of bringing to bear upon the subject the scientific and mechanical intelligence of many, in such an audience as this, and who may assist in the valuable work of developing the means of making sound signals fulfil their purposes with accuracy and precision.

The effective employment of sound-signals appears to be chiefly dependent upon two factors, the facilities offered by the atmosphere as a vehicle of sound, and the human capacity for hearing and distinguishing sounds of different characters. It will, perhaps, be convenient to regard first these two points, and afterwards to deal with the application of sound signalling for various purposes, and the different kinds of instruments used to produce the sounds.

It is hardly necessary, before such an audience as this, to attempt an explanation of the general laws governing the propagation of sound; and, in the presence of so eminent an authority as the learned professor who has so highly honoured my subject and myself by presiding this evening, to do so would show some temerity on my part. It is, nevertheless, necessary for me to put before you briefly various considerations relating to sound transmission, which have a direct bearing upon the matter in hand, but it is only proper for me to observe that in this respect I must borrow the thunder of your learned chairman, and place before you results obtained through his patient investigation, judicial weighing of evidence amid conflicting theories, and unstinted expenditure of time and personal comfort.

The atmosphere is the vehicle for transmission of sound with which we are this evening concerned. Water is an excellent medium for sound travelling, and the possibilities which have from time to time

been suggested in regard to it, require only the attention of inventive genius to bring them within the range of practical reality and utility. But as at present the atmosphere is the only medium which is practically available for the transmission of sound signals, it becomes important to know whether some conditions are more favourable than others for its passage.

It is evident that there are various influences which may be supposed, in one way or another, to affect the transmission of sound. Wind has always been known as a most powerful agent in intercepting and even diverting it. Fog, snow, and rain, have also been regarded by many as serious obstructions, while it has long been popularly considered that a bright, warm, sunshiny day, with little or no wind, was exceptionally favourable for the travelling of sound. These views, it may be said, have grown up as the result of general expectation rather than of scientific observation; but the development of signalling by means of sound has necessitated a more exact inquiry, than has hitherto been made, into the general subject of sound transmission, and the result has been that some of the old theories have been considerably shaken, if not overthrown, while new ones have been set up.

In the years 1873 and 1874, an investigation was carried out, at the instance of the Trinity House, with the object of obtaining some definite information as to the relative merits of sound-producing instruments, and also of ascertaining how the propagation of sound was affected by different meteorological phenomena. Professor Tyndall, as the scientific adviser of the Trinity House, conducted the investigation, aided by a Committee of the Elder Brethren, and some officers of the Corporation. The experiments were extended over a lengthened period, observations being made in all conditions of weather, and repeated over and over again, in order to eliminate error; and the information gained thereby is of the highest interest and importance.

The results are stated at length in the third edition of Dr. Tyndall's book on "Sound," but may be popularly summarised as follows:—That neither rain, hail, snow, or fog, has any sensible power to obstruct sound. From this it is most satisfactory to know that, at those times when a sound signal might especially be of service, the sound is not likely to be obstructed in its passage. That the real obstructors of sound are—first, the wind; and, secondly, what Dr. Tyndall has named acoustic clouds. These clouds have nothing to do with ordinary clouds, fogs, or haze, and may arise from air currents differently heated, or from air currents differently saturated with vapour, and they often exist on days when the atmosphere is in a very transparent condition. The obstruction is caused by the sound, intercepted by the acoustic clouds, being wasted by repeated reflections. In short, it is now established that a bright clear day is not necessarily the best for hearing distant sounds, and that on a day of dense fog it is more than probable that no obstruction is offered to the passage of sounds.

I must not omit to mention that experiments of an elaborate nature, in respect to the propagation of sound in the atmosphere, have also been made under the auspices of the United States Lighthouse

Board, with results mainly corroborating those obtained in the Trinity House trials. In one respect, however, the late Professor Henry, who was at the time Chairman of the United States Lighthouse Board, differed from Dr. Tyndall, viz., in regard to the theory of acoustic clouds, and their resultant aerial echoes. Professor Henry's explanation of the obstruction of sound in clear weather, and the echoes, is founded upon the asserted existence of upper and lower currents of air, the tilting up of the sound wave, and the reflection of the sound from the surface of the sea, or the crests of the waves. From this last explanation, Professor Henry seems to have receded before his death. Into the details of this purely scientific controversy, it is not necessary to enter; but it may be stated, as a matter of fact, that the observations at the South Foreland, and the explanations given of them by Professor Tyndall, have been, one and all, illustrated and confirmed by strict experiment.

One other point may appropriately be alluded to here, viz.—as to the nature of the sound which is most readily propagated through the air, and which, therefore, is most effective for signalling purposes. It appears that what Mr. Alexander Beazeley (who very ably treated this subject of coast fog-signals some years ago) has termed "effective sound range," is made up of two factors, viz., intensity and pitch. It is tolerably well established that initial intensity is the first thing needful, and initial intensity depends upon the actual force employed in creating the sound wave. With suitable apparatus, and an effective application of very high power, there is little doubt that sounds of overpowering loudness may be produced. But the effective range of sound appears to be also controlled by its musical pitch. The short waves of a very shrill or high-pitched sound may appear extremely powerful and effective to observers in the immediate vicinity, but their energy seems to be quickly dissipated, and the sound fails to be appreciated effectively at a distance. Again, the long undulations of a very low-pitched sound do not apparently often reach great distances. It may be that this kind of movement is more readily acted upon by opposing influences, such as reflection or diversion. But, for practical purposes, it seems that the pitch best adapted for signalling lies about the middle of the scale of sound. With sound, as with light, there are wave motions above the highest pitch intelligible to the human ear, and below the lowest sound audible, and it may be, that the nearer sounds approach the limits of human apprehension, so they tend to become less appreciable. In addition to this, it has been found that the atmosphere exercises a selective influence, and, within certain limits, will, under some conditions, favour the transmission of the shorter waves, or high-pitched note; while, at another time, it may be found that the longer waves of a low-pitched note have the advantage.

Speaking generally, the range of sound seems to be attended with much uncertainty. It is popularly supposed that if a sound, at any one time, is heard ten or fifteen miles, it must necessarily be an exceedingly powerful sound. Now, this does not follow as a matter of course. The variability of the atmosphere will throw out any

ation made upon such an hypothesis. In the months at South Foreland, in calm, clear air, one of the instruments was, on a certain day, heard at a distance of 16½ miles, but on another day, with apparently identical weather, the instrument was heard at only 2½ miles off. Obviously, it is no satisfactory test of a signal that on one occasion it had a great—sounds comparatively small and weak have not been audible at long distances—and, here, I need not trouble you now with some of this kind. The true test of a sound appears to be that it shall, under all conditions of weather, be uniformly effective at a distance—say two miles.

Referred just now to what, perhaps, I may say of as the sound spectrum, and to the limits of human capacity in regard to hearing sounds, with the development of signalling by means of sound, I am not sure that the human capacity of hearing and distinguishing sounds of different kinds has received the consideration which it merits. It is granted that you have instruments capable of producing sounds of great power; let it also be said that the signals appear to be distinctive in every way of comprehension, you will, I fear, still find many people in the world incapable of understanding themselves of such signals, either by reason of some or partial deafness, or inability to appreciate differences in sounds. Now, the question that naturally asserts itself, cannot something be done to assist the ear, or, at any rate, the perception of sounds in the air. This seems to be the elementary side of the general question, to which but little attention has been given. In relation to visibility, you have telescopes and binoculars, by means of which a distant object can be brought more plainly into view. But nothing of real value has been done to assist the ear. The old-fashioned ear-trumpet for deaf people is little, if at all, improved. Some years ago an effort was made in this direction by a man from Glasgow, who devised what he named a phonoscope. This instrument consisted of a sort of metal helmet for the head, with an opening like the bent cowl of a steamship, which could be directed towards any sound required. This cowl was supposed to act as a collector of ingathering of sounds, which were conducted to the ears by two small tubes, each terminating in a button, intended to go just inside the ear.

The faults of this apparatus were, first, its clumsiness, and, secondly, the remarkable way in which all the ordinary small noises around the collector and magnified into large ones, and, combined with other sounds hitherto unheard, created a general uproar in the ears. The object this gentleman had in view deserved more success than it obtained. He wished to assist the mariner in picking up and locating a ship at sea; and, although his apparatus acted well that it picked up noises of all kinds, and what bewildered the sense of audition, yet I repeat to say that if any one were to accomplish successfully what this gentleman so perseveringly attempted, a very great public benefit would be gained about. I do not mean to convey that there is specially wanted is an improved ear-trumpet for deaf persons, but, rather, an instrument intended to aid people with fair hearing,

or to render sounds, in some way, more easily perceptible. The late Professor Henry, of Washington, in carrying out his experiments, devised what he termed an artificial ear, by which the relative power of different sounds could be determined at short distances. This instrument consisted of an arrangement by which sound, on a stretched membrane, assumed certain definite forms, or was more or less agitated, in response to different sounds. As a phonometer, at short distances, this instrument appears to have been fairly effective, but it does not meet the want which appears to me to exist. With the growing use of sound for various purposes, there is scope for inventive genius to produce a phonoscope, which shall be capable of assisting the listening ear in a manner analogous to that by which a telescope aids the seeing eye.

The following is a general statement of the chief purposes for which sound signals of different kinds are in practical operation:—

1. *Railways*.—Whistles of locomotives, and explosives as fog signals.

2. *At Sea*.—For merchant ships, the international regulations for preventing collisions at sea prescribe, as a compulsory requirement, that in fog, mist, or falling snow, whether by day or night, the signals described as follows, shall be used:—

(a.) A steamship, under way, shall make, with her steam whistle, or other steam sound-signal, at intervals of not more than two minutes, a prolonged blast.

(b.) A sailing ship, under way, shall make, with her fog-horn, at intervals of not more than two minutes, when on the starboard tack, one blast; when on the port tack, two blasts in succession; and when with the wind abaft the beam, three blasts in succession.

(c.) A steamship and a sailing ship, when not under way, shall, at intervals of not more than two minutes, ring the bell.

And, as an optional proceeding, that a steamship, under way, may indicate her course to any other ship which she has in sight, by the following signals on her steam whistle, viz., one short blast to mean, "I am directing my course to starboard." Two short blasts to mean, "I am directing my course to port." Three short blasts to mean, "I am going full speed astern." A gun fired at intervals of about a minute is one of the authorised signals of distress at sea. In the Royal Navy the above regulations are also in force, but, in addition, Captain Colomb's system of sound-signalling is employed in fog, for the purpose of communicating between H.M. ships. Guns were formerly in use as fog signals, but are seldom if ever employed now.

3. *The Army*.—The only sound signals systematically employed appear to be those made with the bugle.

4. *Coast Fog Signals*.—By far the most important development of sound signals is in connection with the lighthouse and coast-marking service. The most powerful lights are unavailing at night if enshrouded with fog, and, by day, buoys, beacons, and other marks and signs of the sea, are then rendered useless. The necessity for sound signals to do duty at such times for the obscured lights and hidden sea-marks, has brought

about the development of a system of coast fog signals, in which development, so far as the English coast is concerned, the Corporation which I have the honour to serve, aided by your distinguished chairman, Mr. James N. Douglass, the Trinity House engineer, and others, have had a large share. The Commissioners for Lighthouses in Scotland and Ireland, aided by their respective engineers, have also taken vigorous measures for guarding their coasts with fog signals when necessary. It is proper, however, to observe that the lighthouse authorities in the United States took up the matter practically before it engaged much consideration in this country, owing to the east coast of America being in an exceptional degree liable to the visitation of fog, by which the coasting traffic was seriously inconvenienced; and the necessity arose for something to be done whereby the difficulty might be obviated. The ready genius of the country was not long in coming to conclusions, and although some kinds of sound signals, such as bells, gongs, &c., were employed in Europe, the Americans first brought into use Brobdignagian trumpets, whistles, &c., to which I shall refer in due course.

We will now pass on to consider the different kinds of instruments employed in connection with the various purposes to which I have referred.

**Bells.**—Bells, from the earliest times, have been employed to convey intimations by means of sound. Their chief uses in olden times have been summed up in the following:—

*"Laudo Deum verum, plebem voco, congrego clerum,  
Defunctos ploro, postem fugo, festa decoro."*

In these days churches have not a monopoly in regard to the use of bells. The town-crier, the muffin-seller, the railway-porter, and many others signalise themselves by the ringing of bells. With these, however, we are not concerned, unless we may express an opinion that in some of these cases it would be an addition to the public comfort if they were suppressed.

The present regulations for preventing collisions at sea require that, in fog, mist, or falling snow, "a steam-ship and a sailing-ship, when not under way, shall, at intervals of not more than two minutes, ring the bell." These regulations are international, but the Turkish Government have objected to the use of bells as fog signals on board Turkish vessels, on the ground that it is against their religion to use bells on board ship; and, therefore, in all cases where the regulations require a bell to be used, a drum will be substituted on board Turkish vessels.

As warning signals, bells have been employed from a very early date. It is impossible to say when, or where, the first bell was put up to assist mariners; but we may quote the often-narrated tradition, handed down by an old writer, respecting the Bell Rock:—

"By east of the Isle of May, twelve miles from all land, in the German Ocean, lies a great hidden rock, called Inch Cape, very dangerous for navigators, because it overflowed every tide. It is reported in old times upon the said rock there was a bell, fixed upon a tree or timber, which rang continually, being moved by the sea, giving notice to the sailors of the danger. This bell, or clocke, was put there and maintained by the Abbot of Aberbrothock; and, being taken down by a sea pirate, a yeare thereafter he perished upon the same rock, with ship and goods, in the righteous judgment of God."

The story, it is true, is only supported by tradition, but it serves to show that the notion of marking a hidden danger by a sounding bell was certainly in existence—if not practically applied—at a very early period. We know it was practically applied at Poolbeg, in Ireland, in 1811, and at the Bell Rock, in Scotland, in 1812; and we also know that, up to the year 1860, bells were established, to be sounded in foggy weather, at many other lighthouses on the coasts of Great Britain and Ireland, and of France, the United States, and other countries, many of which continue to be sounded at the present day. These bells vary in weight

from 3 cwt. to 45 cwt., and are generally struck by means of clockwork. In no case does the bell itself move, the clapper, or clappers, alone being actuated by the machinery. It is well known that the sound of a bell is curiously fluctuating. In the open country or at sea, in the neighbourhood of church bells, the sound may be heard rising and falling, the peal swelling out as if close at hand—now fading into the thinnest sound, as if retreating far, far away. These effects are familiar to most people, and in themselves are really beautiful; but they come into play injuriously when the sound is wanted to be evenly distributed over a certain area. The truth probably is, that the vibrations from the largest bell are not of sufficient intensity to yield a sound capable of overcoming opposing influences, even of a slight nature. The sound produced in the immediate vicinity of the bell seems, no doubt, exceedingly powerful, the greatest energy of vibration being there exerted; but, at moderately long distances, this apparent energy is dissipated, and the bell ceases to be of use. It will be easily understood that little dependence can be placed upon bells as trustworthy sound signals for long distances. The effective sound range of the largest bell is at all times very doubtful; the wind may carry it to a distance even of 10 or 12 miles, but against the wind it may be inaudible at less than a quarter of a mile.

In one form the bell continues to be serviceably employed, viz., when fixed on the top of a large

with four hanging clappers around the out-  
of the bell, which alternately strike the bell  
buoy is moved from side to side by the  
of the waves. An incessant tolling is thus  
up; and at night, or in foggy weather, the  
is most useful to mark the turning points at  
entrances to important ports, and at other  
where the navigation is intricate, or to mark  
dangers. The number of bell buoys round  
ritish coast is considerable.

ags.—The next kind of sound-producer we  
to notice is the gong. To most of us, pro-  
r, the gong has an inviting sound, that is, as  
for signalling purposes in our households.  
strument has been appropriated for use on  
the light-vessels round the coasts, owing,  
bly, to its peculiar distinctive sound. The  
used in the Trinity House service are about  
et in diameter, of Chinese make, and cost

£4 each. They are struck with a stick  
a padded head, the strokes being very  
and delivered in quick succession, so as  
ing up the gong into a vigorous state of  
tion. The sound is undoubtedly distinctive,  
erviceable at very short distances; but, like  
und of a bell, is soon dissipated after leaving  
mediate vicinity of the instrument. Passing  
may approach nearer to a lightship than  
cky coast marked by a lighthouse; there-  
a sound with only a short range may often-  
be of great service. In many lightships,  
r, the gong as a fog-signal is now super-  
l by instruments of very much greater power.  
and Explosive Signals.—Guns are used for  
as purposes in connection with signalling.  
minute gun at sea," indicates that some-  
is in distress, and that assistance is required.  
s one of the authorised distress signals. On  
H.M. ships, guns have been employed for  
ling in foggy weather, in accordance with an  
ged code; and for salutes and other announce-  
s, they are used at military depôts and else-  
s. But their chief service has been as warning  
ls on headlands and dangerous points on a  
to assist the mariner in foggy weather. The  
ity for distinctiveness in the use of sound  
ls, and the loudness of the report yielded by  
ischarge of cannon, led to the adoption of this  
of sound producer.

re is no doubt that these gun signals have  
of the greatest value. Many and many a  
the warning gun has been heard by the  
dared seaman in time to enable him to alter  
urse, and probably save his vessel. Formerly  
uns were fired every fifteen minutes, but  
ly the interval has been altered to ten  
es. It would be difficult for two men to

clean, load, and fire, for a lengthened period—say  
even twelve hours—with less intervals than ten  
minutes between each discharge.

The piece of ordnance ordinarily employed was  
the old long 18-pounder, with a 3-lb. charge of  
powder; but in the Trinity House experiments at  
the South Foreland, it was found that a short  
gun, the 24-lb howitzer, gave a better sound than  
the long 18-pounder.

Professor Tyndall thus sums up his opinion of  
the gun as a fog signal:—

"The duration of the sound is so short, that, unless  
the observer is prepared beforehand, the sound, through  
lack of attention, rather than through its own power-  
lessness, is liable to be unheard. Its liability to be  
quenched by a local sound is so great, that it is some-  
times obliterated by a puff of wind taking possession of  
the ears at the time of its arrival. Its liability to be  
quenched by an opposing wind, so as to be practically  
useless at a very short distance to windward, is very  
remarkable."

Professor Tyndall continues:—"Still, notwith-  
standing these drawbacks, I think the gun is  
entitled to rank as a first-class signal."

In 1874-76, some experiments were made at  
Woolwich Arsenal, with the view of reducing the  
labour of firing, so as to enable two men to fire at  
more frequent intervals, and also to produce, if  
possible, a more effective report than had been  
obtained by discharges from guns of ordinary  
pattern. Colonel Eardley Maitland, of the Royal  
Gun Factories, Woolwich Arsenal, devised a form  
of gun, breechloading, with six chambers, similar,  
in some respects, to a revolver, and with a parabolic  
mouthpiece fitted to the muzzle. The experiments  
gave promise that this fog signal gun would prove

a success, and ultimately it was conveyed to  
the North Stack, near Holyhead, in order  
that it might have a practical trial. To reach  
the station, it was necessary to cross very bad  
mountain roads, and the gun received a severe  
jolting, and probably jarring, for it broke down  
shortly after being used. No further attempt  
was subsequently made to repair the damaged gun,  
nor to manufacture another, owing to the attention  
of the Trinity House being then diverted to  
gun-cotton as an explosive sound-producer. It  
should also be mentioned that, in the trials at  
Woolwich, one experiment was devoted to testing  
the comparative advantages of the various kinds  
of service powder for noise-making purposes. The  
powders tested were—(1), F. G. (fine grain); (2),  
L. G. (large grain); (3), R. L. G. (rifle large grain);  
and (4), P. (pebble). In point of effectiveness in  
sound-producing, the result of the trial placed the  
powders exactly in the order in which I named

them; the fine grain, or most rapidly burning powder, giving indisputably the loudest sound; while the report of the slowly burning pebble powder was the weakest of all. The 80 and 100 ton guns, fired with charges of 300 and 400 lbs. of pebble powder, do not make anything like so terrible a noise as the enormous charge would lead one to expect. The sound seems to lack intensity; and, in comparison with the sharp smack of the detonation of gun-cotton, or of a much smaller charge of more rapidly burning powder, appears to be more of a prolonged and somewhat soft roar.

While upon the subject of guns, I must not omit to refer to the very ingenious invention of the gas gun by Mr. J. R. Wigham, of Dublin, the advantages claimed for which are that, where a supply of gas is available, the apparatus is very easily applied, and that the gun can be loaded and fired at a considerable distance from the point of explosion. The gun consists merely of a tube about 18 inches bore and 12 feet long, placed at the point where the signal is required to be made, and connected with a gas main or gas-holder, by iron piping. The gun is loaded with an explosive mixture of gas and atmospheric air, by turning on a cock simply, and is fired by a light applied by percussion or otherwise to the shore end of the tube, the explosion taking place at the mouth of the gun almost immediately. Mr. Wigham states that a gas gun may be fixed at the water's edge, or on a rock in the sea, at half a mile from the loading and firing station. The idea, which is certainly one of originality, was conceived by Mr. Wigham when he was engaged in connection with the application of gas to the lighthouse at Howth, Bailey, and his experiments at that station have met with a very encouraging amount of success, but the system is not yet in practical operation as a fog signal.

In 1874, the Trinity House obtained the consent of the War Department to some experiments being made at the Royal Arsenal, with the object of ascertaining the value of the sound produced by the explosion of varying quantities of gun-cotton. The explosion of gun-cotton takes place so instantaneously, that an exceedingly sudden and sharp blow is given to the surrounding air, whereby a sound wave of great initial intensity is generated. A number of comparative trials were made at Woolwich and elsewhere, in which the superiority of gun-cotton over gunpowder was incontestably demonstrated. It was found that charges of gun-cotton, however fired, yielded reports louder at all ranges than equal charges of gunpowder; and further experiments proved that the detonation of half a-pound of gun-cotton gave a result at least equal to that produced by the firing of a 3-lb. charge of gunpowder. During these experiments, the various charges of gun-cotton had been merely suspended from a horizontal bar, or in the focus of a large parabolic reflector, and fired by means of electricity. To explode gun-cotton, it is necessary to employ a detonator, consisting of a small cylindrical copper case, resembling an elongated percussion cap, containing a certain quantity of fulminate of mercury. This detonator is inserted in the heart of the portion of gun-cotton to be exploded, and an attachment is then made with one wire, connected with a small electric machine, and with another attached to a conducting-plate embedded in the

earth. On turning the handle of the machine, current is induced sufficiently strong to generate a spark at the connection of the wires with the detonator, which, coming in contact with the minute of mercury, immediately explodes it, and instantaneously the explosion is communicated to the gun-cotton. If gun-cotton in a wet state is used, it is necessary to have a small plug or plug of gun-cotton, into which the detonator is inserted. Four processes then take place, viz.:—1. Generation of electric spark. 2. Ignition of detonator. 3. Communication of explosion to dry primer. 4. Communication of explosion of dry primer to wet portion. The entire operation is, however, perceptible to the human sense as one explosion only. It will be readily understood that the charge of gun-cotton in this way entailed some expenditure of time and trouble, and might be inconvenient, if required to be repeated every few minutes for many hours during fog.

But it being clearly demonstrated that the explosion of gun-cotton gave a very effective signal, a project emanated from the Deputy-Master of the Trinity House (Admiral Sir Richard Collins, K.C.B.), for making a rocket serviceable for conveying a charge of gun-cotton up to a certain height, and then causing it to explode. This project, with the aid of Mr. Brook, the well-known rocket technician, and, subsequently, Mr. Mackie, an officer of the Woolwich Arsenal, after numerous experiments, made a practical success; and at five stations on our coasts, we have rockets, either substituted for guns previously or established *de novo* for signalling in weather.

The following description of the rocket now

is given in the instructions issued to the fog signal attendants at Flamborough-head, where these rockets have been in use since January, 1878. The explosive used is a slight modification of gun-cotton, called tonite, which is said to be cheaper than ordinary gun-cotton, and as effective for producing a loud report.

**SECTION OF ROCKETS.**—For purposes of safety, test is supplied, and is to be kept, in three parts,

**The Rocket.**—This is a case charged with the y rocket composition, and is intended merely to p the explosive charge to the required height, so to ignite the detonator which is to explode in.

**The Detonator.**—This is an enlarged percussion-fused with fulminate. Its duty is to cause an m to take place in the heart of the tonite , whereby that charge is exploded. The de- r is ignited by the burning of the rocket dition.

**The Tonite Cartridge.**—This is the explosive produces the report, and which, with the de- r placed inside it, is to be fitted in the head of the, when immediately required for use."

Fitting together of the three parts can be plished in less than a minute; the rocket is ighted by applying an ordinary fuse to a of Bickford fuse, communicating with the . composition. The whole operation occupies an two minutes. The cost of the rocket is la. 3d., whereas each discharge of the gun la.; and in foggy weather a rocket is sent up ten minutes. The advantages gained by the action of the sound rocket are indisputable, particular more especially.

requently happens that the sound of a signal led to be spread over an arc of, say, 180 as to seaward, is obstructed, or deflected, by ening obstacles, so as to cause certain parts e arc to be immersed in sound shadow, into . the sound penetrates with very feeble effect, ften not at all. This difficulty the rocket has nited most successfully.

explosive charge is carried up to the height out 800 feet, and is there caused to explode e air. From the height at which the explo- takes place, the direct sound is sent down- e into places which would be completely n from the level at which a gun could be , and which would seldom be reached by the d of its discharge. At Flamborough Head, gun was placed on the extreme edge of the t, the cliffs being about 100 feet high. But in lington Bay, at a very short distance to the i-westward, the gun was invisible at the sea

on account of intervening faces and edges of iffs. A practical trial of the rocket versus the t this station clearly showed the value of the r. One man walked along the edge of the keeping the gun in sight, and several observers below on the rocks at the foot of the cliff, it low water at the time. It had been arranged upon intimation from the observers below,

an above should signal to the people at the station to fire, first a rocket, then a gun. At a er of a mile from the point, with a light wind et the sound, the first experiment was made. ocket gave a loud and sharp report, the gun a heavy thud. At half a mile the rocket was lead, the gun very faint. At  $1\frac{1}{2}$  mile the t was loud and distinct, the gun heard only o observers, and then only with the most ed attention. The fact of the explosion of what having been visible and audible on each en, shows that it was clear of the obstructions ; quenched the sound of the gun, and hid its gns from sight. It should also be mentioned

that the charge of the gun is 3lbs. of powder, and that the explosive charge of the rocket consisted of 4oz. of cotton powder.

The sound rocket is now in use at Flamborough Head, at Lundy Island, the Smalls Rock, in St. George's Channel, at Heligoland, and at the Tuskar Rock, on the south-east coast of Ireland. The system offers the means of placing an effective fog-signal at a rock lighthouse station, where limited space and accommodation would prevent the establishment of a gun, or signal requiring furnace and machinery.

The development of explosive coast fog-signals has not gone beyond this point. Gun-cotton and cotton powder (or tonite) may be handled and stored with quite as much safety as gunpowder; in fact, they are really less dangerous; but it has not yet been shown that other explosive compounds, such as dynamite, lithofracteur, blasting gelatine, or any other nitroglycerine mixture, can be made practically serviceable. Some freeze at a temperature a little above 40° Fahr., and others do not lend themselves to manipulation, and to safe storing for lengthened periods. There is, however, every probability that further advances will be made.

One other form in which explosive signals are now used may here be mentioned. I have alluded to the gun fired at intervals of about a minute being the authorised signal of distress for ships at sea. Mr. Gardiner, of the Cotton Powder Company, has sent me particulars of a kind of signal which may be fired more easily, expeditiously, and effectively than the gun, thereby obviating loading every minute, an important consideration with a vessel in distress. This consists in a small charge of tonite made up into a sort of cartridge. When required to be used, one of these cartridges is dropped into a socket, and by pulling a lanyard attached to a friction tube, a small quantity of powder at the base of the signal is ignited, which blows the charge up into the air about 600 feet, where it explodes. At the moment of explosion some brilliant stars are also shot out, and thus the signal represents either a gun or a rocket, both distress signals. I am informed that many vessels have been supplied with these rocket signals, that their effectiveness is undoubted, and that the Board of Trade have sanctioned their use in lieu of either guns or rockets.

One further application of explosives requires attention, one probably more familiar than agreeable to most of us. I allude to the use of exploding signals on railway lines, to convey signals to engine-drivers and guards in foggy weather, and to do duty for the semaphores and coloured light signals when they are obscured. The system appears to be, that a signalman, furnished with a supply of detonators, places himself near to the signal-box or semaphore in connection with which he works, and uses the detonators to stop a train, if the line is blocked by the fixed signal. The detonator consists of a small quantity of coarse gunpowder, tightly bound up with three percussion caps; it is fixed on the rail with lead clamps, and is exploded by the wheel of the engine going over it. The system is said to be fairly effective; but it is probable that the British public generally would not endorse that opinion, for most people are fully aware of the annoying delays involved by the system, and certainly do not relish

the sudden explosions to which they are treated, while chafing under enforced detention in the train. There seems to be plenty of room for improvement; the system is cumbersome, and admittedly expensive; and we may well hope that a more effective and less objectionable method of signalling in fog may be devised for our railways.

**Whistles.**—The next instrument which claims our notice is the whistle. We will first regard it in connection with coast fog-signals. For this purpose, whistles, whether operated by steam or compressed air, do not appear to have found so much favour in this country as in the United States and Canada; indeed, with the exception of one station in the Clyde, where two small whistles, sounding different notes, are in operation, there are no fog-signal whistles on our coasts. In the United States they have been employed at various points since the year 1851. The first was set up by Mr. C. L. Daboll at Beaver Tail Point. In Canada, also, whistles have been in use for some time, the type adopted being that invented by

Mr. Robert Foulis, of St. John's, N.B., and known as the Vernon-Smith whistle; and in this country, Mr. W. H. Bailey, of Salford, Manchester, has given much attention to the manufacture of whistles suitable for sound signalling. Steam whistles are simple enough in their arrangements, requiring only a boiler for generating steam, and a simple mechanical arrangement for opening a valve for the periodic passage of the steam to sound the whistle.

For air whistles, it is necessary to have some motive power to compress air, and also some mechanical arrangement to regulate the admission of the compressed air to sound the whistle.

In the Trinity House experiments of 1873-4, it was shown that the sound of the most powerful whistles, whether blown with steam or air, was generally inferior to the sound yielded by other instruments, and, consequently, no steps have been taken to extend their use in this country. Various reports have been circulated as to the great distance at which whistles have been heard on the American and Canadian coasts, but no such results as those claimed were obtained in the very careful trials, made with both American and Canadian whistles, at the South Foreland, in 1873.

The sounding of a whistle is caused by the vibration of the column of air contained within the bell or dome, the vibration being set up by the impact of a current of steam, or air, at a high pressure. It is probable that the metal of the bell is likewise set in vibration, and gives to the sound its *timbre*, or quality. It is to be noted that the energy so excited expends its chief force in the immediate

vicinity of its source, and may be, therefore, regarded as to some extent wasted. The sound of the whistle, moreover, is diffused equally on all sides. These characteristics, to some extent, explain the impotency of the sound to penetrate to great distances. Difference in pitch is obtained by altering the distance between the steam orifice and rim of the dome; when brought close to each other—say within half an inch—the sound produced is very shrill, but it becomes deeper as the space between the rim and the steam or air orifice is increased.

The most recent adaptation of the whistle as a fog-signal is shown in an automatic signal buoy,

devised by Mr. J. M. Courtenay, of New York, by which a powerful whistle, fixed at the top of a buoy, is sounded automatically by the action of the sea. The apparatus consists of a buoy, 18 feet in diameter, with a tube 33 inches in diameter, and 32 feet in length, passing vertically through the centre, and descending below the bottom of the buoy to a depth of about 20 feet, the object of this length of tube being to reach a depth where the water is not subject to wave agitation. The bottom of the tube is open, and freely admits a column of water, which is maintained at a constant level, and is not affected by the external superficial wave motion. The buoy, however, to which the tube is fixed, moves with the surface undulations of the water, and, of course, carries the tube up and down with it, thus establishing a piston and cylinder movement, the column of water in the tube forming a piston, and the tube itself being a moving cylinder, the weight of the buoy and the tube exercising a considerable pressure. By means of the motive power so established, air, which is admitted by stop-valves into that part of the tube which is above the level of the water, is compressed and forced through a pipe 2½ inches in diameter, communicating with and sounding the whistle at the top.

One of these buoys has been practically tried off the Goodwin Sands for some months, and has proved a success; two more are about to be placed at other points. On the coasts of the United States, France, and Germany, they have also been in successful operation for several months.

Whistles are supposed to be the best medium for making signals by sound on board steam-ships. The regulations which I have previously quoted,

he whistle for steamers; but it is necessary precaution should be taken to ensure sties giving effective sounds. Many stened to appear to me to be dismal more especially when first sounded, for y the condensed steam causes so much the pipe, that when a sound signal is re- be made in a hurry, only a rush of water rough, without any effective sound.

ard the *Duke of Leinster* steam-ship, run-ween Glasgow and Dublin, a novel form le consisting of an organ pipe fitted on to sm-pipe, is said to give very superior

It is said that it does not get choked ary whistles; and that the sound emitted and resonant, without the shrill distone of many whistles. This instrument ed by Messrs. Hannan and Buchanan, of

regard to the use of whistles on locomones, I have endeavoured to ascertain from entlemen connected with railway engineer-whom I beg to offer my best thanks for rtesy in replying to my inquiries), whether l of signal is the best for the purposes re-and from the replies I gather that the s, "Well, it might be better, but it just " It does not appear that much is known by engineers about the construction or shape of and they seem to share the popular notion shriller the sound the more effective it is. I may here venture, in the general interests avelling public, to utter a protest against siderate and often unnecessary manner in histles are sounded in the great railway of this country, and London in particular. It probable that this meeting will sympa-th me when I say that, in these days of susceptibility, and when so many thousands le travel daily by rail, something ought to by the railway authorities to abate the e of unnecessary whistling, and certainly to n the sudden, shrill, ear-piercing screeches, ake a strong man's nervous system tingle nd which echo from roof, wall, and ground berating shrieks. There is enough hubbub et at all stations, caused by the bustle of e, the arrival and departure of trains, the g and banging of doors by porters; and all this may be called exhilarating, yet the of whistle screeches is too much to im-on an enduring public. Drivers and stokers, air deadened perceptions, are probably not f the real pain they often inflict on many by their thoughtless use of the whistle. i-signals are so necessary, let them be low, nds, or a full-toned bell. Such as are used motives in the United States would be a lief.

**Horns.**—The next class of instruments to reference should be made is the horn, or t, in which air or steam pressure is em-to set in vibration a metallic reed, or tongue, vibration is communicated to air inside the t, and also to the molecules of the metal of he trumpet, or horn, is formed.

J. L. Daboll, of the United States, to whom e has been previously made, introduced, an instrument of this kind to the notice of ed States Lighthouse Board, and a trial

was made at Beaver Tail Point, Rhode Island. This instrument was sounded with air condensed by two air pumps, worked by a horse, the compressed air being stored in a receiver, and the trumpet sounded at a pressure of about 40 lbs. to the square inch. Ultimately, Mr. Daboll employed Ericcson's caloric engine as the motive power for condensing the air, and an automatic arrangement for regulating the blasts, and in 1862, he introduced his improved signal to the notice of the Trinity House Corporation, who gave it a practical trial at Dungeness. The results being very satisfactory, the Corporation placed other instruments of the same kind at several places round the coast, and one was fitted up on board the *Newarp* light-ship. The experiments at South Foreland showed such instruments to be, under some conditions, very efficient, but they suffered from several disadvantages, which have led probably to their disuse of late years. I have alluded to the fact of some of the initial power being wasted in the case of whistles, by the metal of the dome, or bell, being set in vibration; this occurs to a greater extent with the huge brass trumpets which have

generally been associated with reeds. In a paper read before the Royal United Service Institution, in May, 1875, Admiral Sir Richard Collinson, in speaking of these horns, says that "there are objections to the trumpet being made of brass, and also to the necessity which exists for tuning the reed in unison with the fundamental note of the trumpet." Sir Richard goes on to remark, "the use of a trumpet consists chiefly in concentrating the sound into a beam, and thus causing it to be projected through the air with greater force in any required direction. The brass trumpet, no doubt, does this to a certain extent; but as the molecules of the metal are also set in vibration, sound waves appear to be generated from all parts of the external surface of the trumpet, so that, although a very loud sound may be produced in the immediate neighbourhood of the instrument, it is open to doubt whether that sound is transmitted with force to any great distance, its strength being, so to speak, dissipated in the space close to its source." The local noise occasioned by the vibration of the trumpet would be intolerable for any length of time. At the present time there are very few reed instruments with brass trumpets in operation, many of those originally established having been superseded by the siren, an instrument of which I shall speak presently. In connection with the development of reed horns very much is due to Professor F. H. Holmes, whose energy in connec-

tion with the electric light is well known. Under his immediate superintendence and advice two reed horns, sounded directly by steam, were fitted on board two light-vessels sent out to China, and have worked very satisfactorily.

Reed horns are also used on board ship, chiefly sailing vessels, in compliance with the compulsory fog-signals, and the optional sound signals, in connection with the "rule of the road" at sea. The horns now exhibited are lent for this evening by Mr. Nathaniel J. Holmes, of Holmes' Marine Life Protection Association (Limited). They are said to be very effective, but in a seaway, with the vessel rolling heavily, the seaman has some difficulty in working the instruments. It is air pressure which sets this reed in vibration, and produces the sound. In some trials recently made by the German Admiralty, these horns held a commanding position.

Recently, there has been brought into this country, from the United States, an apparatus known as Barker's marine safety signal, intended for use on board ship, to make sound-signals. The apparatus has many merits, one of which is its simplicity in working; a second is that every signal is sounded automatically when once set, and a third is that, with the horn attached, it gives a very good sound. Compressed air is employed at a pressure of 6 lb. to the square inch, and the sounding principle is a reed for the horn; but the inventor says, it can be equally well connected with the steamer's own whistle. The main object of the inventor appears to be to bring into use a short code of compass signals, by means of which vessels can indicate to one another their respective courses, the signal system consisting of eight combinations of long and short sounds. But it may be observed that the adoption of his code would make it necessary for the law to be altered, there being no permission or obligation to employ such signals in the rules now in force. And, again, the principle of long and short sounds which has been adopted, does not command itself for service at a moment when there is no time to lose in deciphering the meaning of a sound signal from an approaching vessel. Captain Barker, however, has evidently had these considerations in his mind, for, in his descriptive pamphlet, he remarks that, though numbers of practical seamen consider the suggested code to be the simplest and best as yet brought forward, its adoption is by no means a *cine quæ non*, since the machine can, with equal facility, blow any code which may be decided on. Captain Barker would probably do well to adapt his machine to sound only those signals provided for in the regulations.

**Sirens.**—We now come to the instrument which has been authoritatively described as "beyond question the most powerful fog-signal which has hitherto been tried in England." In 1872, a Committee from the Trinity House, who went to the United States, witnessed the performance of an apparatus known as the siren, and patented by Messrs. Brown, of Progress Works, New York, and in the experiments at the South Foreland one of these instruments was sent over to be tried.

The instrument sent from America could be sounded either with steam or compressed air, made to pass through a fixed flat disc, fitted into the throat of a long trumpet, connected with the steam or air pipe. This disc has twelve radial slits, and behind it is a rotating

disc, with twelve similar slits, the being effected by separate mechanism. Then, the pressure of steam or air to be a disc fixed, and the other rotating; it will stand that the slits in each frequently in fact the twelve slits in one revolution

Enlarged view of Siren Disc.

twelve times, and at each coincidence steam or air, at great pressure, escapes into the trumpet. It is the rapid succession of these puffs which form the sound of the disc is rotated so as to make 2,400 rotations a minute; and as there are twelve coincidences in each revolution, it follows that the number of puffs passing through in a minute would be  $2,400 \times 12 = 28,800$ .

It can readily be understood that a surpassing power is thus generated, and the vibrations produced are not taken up by the iron trumpet, the sound issues from the a condensed beam of great intensity.

It is not of importance to record the distances at which the siren has been heard, sound-range under different atmospheric conditions being so exceedingly variable regard to its superiority over other means, we may say that, under meteorological conditions unfavourable to the transmission of sound, the voice of the siren had a greater range than that of any other sound-producer; when local noises—such as those of waves, rattling of rigging, breaking waves, surf, paddle-wheels, and the working of machinery have to be contended with, "its dense pitch, and penetration, render it dominant over such noises after all other signals have succumbed." It is obvious that this overcomes obstructions is the true test of the value of a sound signal, and it is surprising that the experience of the South Foreland should have led to the extensive adoption of this form of fog signal on the coast of Great Britain. Since 1874, 22 sirens have been placed at the most dangerous stations on our coast, and 16 on board ships, moored in positions where a guide of the greatest service to the passing vessels. It should be added that, in the experiments alone was used for sounding the sirens, the instruments now in operation on our coast are sounded with compressed air, the motive power being calorific engines of greatly improved construction, examples of which are given at the Lizard, both for the electric and the fog signal. Steam is not used at many lighthouse stations, owing to a lack of fresh water; and the calorific engine, v

the siren disc, is regarded as safer and economical in working than a high-pressure siren, and is independent of water supply. It has been employed with considerable success in the United States, Canada, and some other countries. With Bailey, a gas-engine is employed as for compressing air for the siren now in use there. This arrangement is due to Mr. W. J. Bailey, of Dublin, and is said to work very

Stevenson, of Edinburgh, have proposed Perkins engine should be employed as a siren for siren signals, but I am not aware suggestion has yet been carried out.

The Siren as the most efficient signal for use in foggy weather, may be regarded as an important epoch in the history of development of the use of such signals. Instruments have been made by Mr. James N. Smeaton, engineer to the Trinity House; and Mr. Smeaton, superintendent of the Trinity House works, has invented an improved arrangement instead of flat discs being used, the siren consists of two concentric cylinders, with slits in both, the inner one being fixed, and the outer one revolving, with the smallest possible clearance between them. The advantages of this arrangement are, that the suddenness of letting off the pressure is much increased, and the successive blows upon the air are much sharper, and the sound intensity increased. It is also considered an improvement mechanically, by somewhat lessening the friction; Professor F. H. Holmes has succeeded in rendering the rotation of this siren automatic, with perfect control of the speed and consequent pitch, and an apparatus of this kind has not long since been fitted on board the ship at the Seven-stones.

It seems probable that before long the siren will come into more general use for maritime purposes. Already it has been introduced into the Royal Navy, for which service Professor Holmes has applied three small-sized instruments. Messrs. Sautter, Lemonnier, and Co., of Paris, have produced a steam siren, which they can be used not only as a fog signal at sea stations, but also for ships, and, in a land form, for locomotives, in the place of the bell.

Mr. Wigham, of Dublin, has also devised a form of siren for steamships, driven by a steam engine, actuated by the current of steam or air, which the instrument is sounded, the rate of being controlled and rendered uniform by a governor.

Messrs. Sautter, Lemonnier, and Co. have more recently introduced a double siren, in which two cylinders, having different numbers of orifices in their ends, produce simultaneously two tones, the trumpet, and by this means the power of the instrument is more than doubled, and a distinctive feature is given to the sound. I remain to offer a few general remarks on the subject.

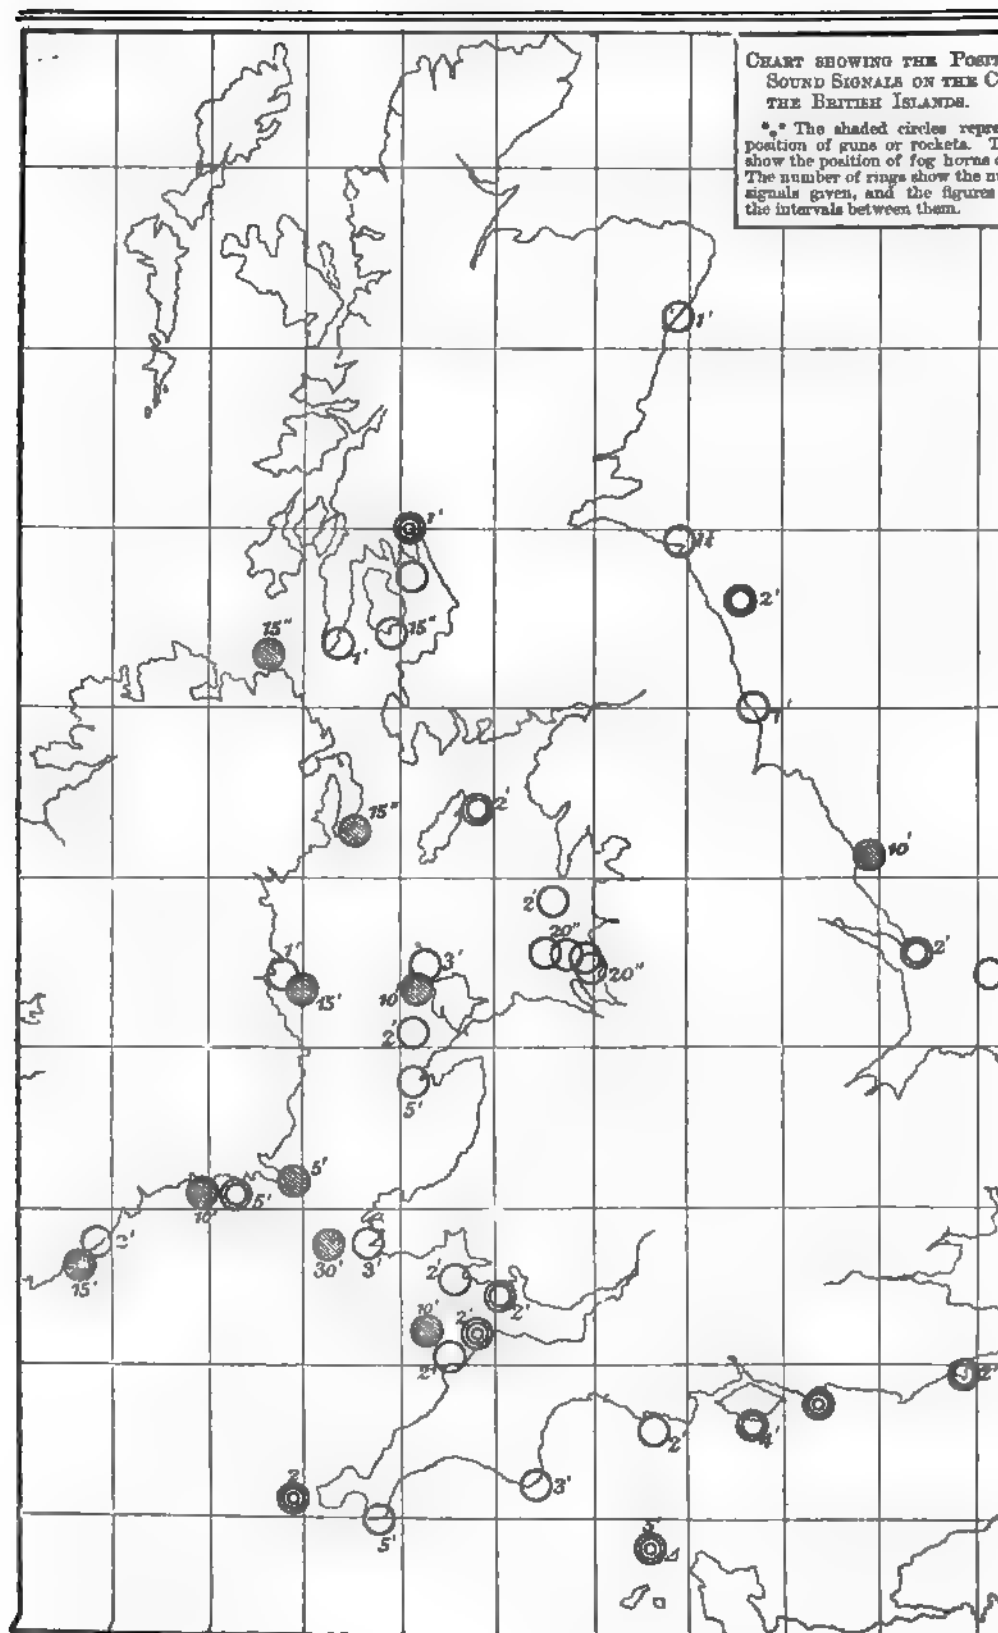

It is obvious that, with the increasing use of steamships, there is an increasing necessity for fog signals. Something must be done to prevent one from being mistaken for the other. In fact, it is necessary that every steamship should have its own characteristic. This

essential element, as regards coast fog signals, has by no means been overlooked, and as each light-house is made to proclaim its own individuality, so every fog signal established on our coast has been made to particularly indicate itself by some distinguishing feature. One great reason why explosive reports, whether from guns or rockets, are made use of, is because their sound is so entirely different from that of the blast of a siren, a reed horn, or a whistle. Indeed, the three latter strongly resemble each other, and can only be distinguished by trained ears. It has also been found useless to attempt to get differential signals by means of pitch of the note alone. To employ a high note at one station, and a low note at another, would, in the present condition of the musical cultivation of mariners generally, be more likely to lead to confusion and disaster; although, as Sir Richard Collinson observed, in 1875, it might be possible to obtain an effective distinction by sounding a high and a low note in direct contrast. It has been frequently proposed to introduce long and short blasts; but here, again, experience has shown that many difficulties and risks would attend such an arrangement, and might result in conveying wrong information to the mariner, and lead him into danger. For real practical utility it has been found that, for the present, it is best to trust to the distinctions which may be obtained by varying the number of blasts, and the length of the silent interval. This is a system which is intelligible to the most ordinary understanding; and, accordingly, it is on this basis that the characteristics of sound signals are founded. By making the blasts to occur in groups, and varying the length of the intervals between the groups, on the same principle as that now applied to the new class of group-flashing lights, sixteen fundamental distinctions may readily be obtained, thus—commencing with an interval of half a minute:—

1 blast every $\frac{1}{2}$ minute	3 blasts every $\frac{1}{2}$ minute
" " 1 " "	" " 1 " "
" " 2 " "	" " 2 " "
" " 3 " "	" " 3 " "
2 blasts " $\frac{1}{2}$ minute	4 blasts " $\frac{1}{2}$ minute
" " 1 " "	" " 1 " "
" " 2 minutes	" " 2 minutes
" " 3 " "	" " 3 " "

The introduction of compulsory and optional sound signals in the new regulations for preventing collisions at sea, has naturally much extended the use of sound signals on board ship, and there can be no doubt that such signals should be entirely different from those made at fixed fog signal stations. It is said that already some difficulty has arisen in reference to the clause in the regulations, which enacts that in foggy weather a steamer shall sound a prolonged blast at intervals of not less than two minutes, the fact being that several coast fog sirens sound the blast every two minutes. Unless checked, this, perhaps, is a danger likely to go on increasing as ships' sound signals become more powerful and more generally used.

One point occurs to me, in connection with those gentlemen who give much time and trouble, and, probably, spend much money, in developing sound signals. I observe that they all take up some special code of signals, and then show how well their instrument is adapted for it. Now, if I might

ness of advice to those gentlemen it would look at the law, and see what signals are, then adapt your apparatus, whatever it is, to making those signals. Don't require it to be altered to suit your instrument—that is a real difficulty in the way; but make instrument suit the law as it now exists.

It is not easy to see how the system of short sounds can at present be brought into satisfactory operation. Such distinctions are very pretty and simple upon paper, but they are a very different aspect in the mind of an uneducated man, not over intelligent master on board his vessel, say in the Downs, in the fog. All around he hears horns and whistles, and all he attempts to do is to keep clear of vessels which, by the sounds, appear to be in the way. Of what use, then, would be the command of long and short sounds? Would he, in a bewildered state, care to try to distinguish them? I venture to say he would have the time nor the inclination to do so; and not be forgotten that, in making provisions for the fog, it is not the skilled, clear-headed, educated, Royal Naval or merchant captain, but the weather-beaten master mariner, as well how to navigate their vessels under circumstances, but whose minds are not for comprehending any system requiring exact and attentive observation, to which is the necessity of finding out the meaning of the observation is made.

As regards the present development of our signals, there is every reason for confidence. A glance at the map will show how severely they have been applied. This method of coast marking has been brought to a very effective condition; no efforts have been spared to cope with the seaman's greatest danger, and the remarks which I have had the pleasure to address to you indicate with what success the matter has been attended. By the aid of the fog, the mariner is now enabled to conduct a voyage with comparative safety, even when the vessel is enshrouded with a thick pall impenetrable by the keenest vision; and there is little doubt that those who have their business in the sea are ready gratefully to acknowledge the spirit which has prompted the development of these signals, as well as the practical value which they derive from them.

#### DISCUSSION.

(Mr. Richard Collinson, K.C.B. (Deputy-Master of Trinity House), congratulated the Society on having Mr. Edwards to prepare this paper. Mr. Edwards was the predecessor to America, and ever since had been, as his private secretary, more or less with all the experiments which had been made, was, therefore, eminently fitted to explain the merits of this system. It was not as yet possible, he had been said, they had still to bring to light and low notes, with which experiments were to be made. The recent rule of the road required steamers to make certain signals in the fog resembling the fog signals on shore; but a difficulty, and it would be necessary to make some distinction. They had received suggestions on the subject of these fog signals, and they were in their favour; but

when a man had successfully made his voyage, he did not think it necessary to say that he had been aided by the fog signal, whereas if he got on shore he was pretty sure to say he did not hear it. The air was such a subtle element that he hoped no seaman would ever put his faith in fog signals, but always have recourse to the lead. What he wished to impress on the seafaring people of the world was, that the fog signal was an auxiliary to navigation, but that it could not always be depended upon. Last year he received a very pleasant letter from Captain Schultz, commanding the Danish frigate *Sjælland*, dated from the Sound, Copenhagen, in which he said, "One, amongst thousands, I offer you my best thanks for what the Corporation has done for mariners in giving them fog horns, especially those at Dungeness and the South Stack light." He then went on to give the details of a voyage he made, starting from Portsmouth in a fog, which showed that he took all the care in sounding which a navigator ought. He concluded by saying, "The end of all this minute description is to show that by going back through the reckoning from our position at half-past seven in the morning, I found we heard the first sound of Dungeness fog-horn to windward at 7½ miles, and lost the sound on the lee side at a distance of 2½ miles." This was gratifying testimony to the value which these signals were to ships. Mariners were now becoming more accustomed to them, and no doubt they would enable vessels to shorten their voyages, but he would again repeat that they should not trust to sound alone.

Admiral Sir Erasmus Ommanney, C.B., F.R.S., mid steam whistles and fog horns had been introduced since he was on active service, but he was glad to learn they were now being reduced to a system, and becoming of such great service to seamen. Living near the Solent, he frequently heard the sound of these horns, and they often puzzled him in listening to them, for he had great difficulty at times in knowing in which direction the sound came; especially in calms. He would, therefore, join in the caution uttered by Sir Richard Collinson, not to trust to sound alone. His only experience of them at sea was as a passenger, but it was enough to show him that if not used with great care, and if there was too much similarity between them, they might lead to confusion and danger.

Captain Sir George Hares, K.C.B., F.R.S., remarked, that speaking, not as a sailor, but as one living for the present on land, it seemed very desirable, while giving the navigators the sound, to screen it from the shore; for they were now creating rather too powerful a sound for the neighbours of the lighthouses and signalling stations. The whole subject of sound signalling was brought about by the question of time. In the old days, they could trust to the lead, turn the vessel's head off shore, and as the depth increased, the mariner knew that he was taking care of himself and his ship, but nowadays they must make their 10 or 13 knots an hour, and, therefore, they must have siren signals to run up St. George's and the English Channel; indeed, these were called for to an increasing extent. Mr. Edwards said he could give 16 different sounds; and that was all very well, but every year the number of ships was increasing; and it was not only the fog signal on shore which sounded, but those from all the ships in the neighbourhood; so that something more than 16 signals was required. They wanted a diversity of sounds, and it had been stated that that was what the Trinity House were now aiming at. They would probably have to introduce different musical notes, and the time might come when every lighthouse would be playing a different tune.

Mr. James Douglass (Engineer to the Trinity House) said he could not add much to what had been said by Mr. Edwards. His part in the matter had been connected with the mechanical develop-

ment of the system. But with regard to Sir E. Ommanney's remark about the difficulty of determining the direction of the sound, he might say that he (Mr. Douglass) had been tested by the Chairman on that special point, he had been desired repeatedly to tell, blindfold, the direction of the sound, and he generally came within half a point of it. When that could be done, he thought you might depend pretty fairly on the direction of a fog signal. It was quite true that echoes sometimes interfered; and when hearing the secondary sound, you might be baffled as to which was the primary one. When you heard vessels sounding horns in all directions, and in addition to that, got echoes from the sides of the vessels and the sails, you had a perfect Babel of sounds, and certainly a coast signal would require a distinct code of its own, which should be unmistakable. He had lately had the honour of discussing the matter with Professor Tyndall, and he then thought there was a possibility of a code being formed, perhaps by a combination of high and low sounds, succeeding each other in rapid succession, by which light-houses and light vessels would give perfectly reliable signals. With respect to the siren, when the original form, with the disc, came into their hands, it was found to be the most efficient signal then known, but they were now able, by Mr. Slight's improved form with cylinder, to economise the quantity of air or steam used, so that the same result was obtained with one-third the quantity, and, consequently, with a like economy of motive power. There was, further, the application of the controlling power or governor, invented by Professor Holmes, so that they could now make an automatic siren, requiring none of the gearing used in the old form. This could be constructed so as to produce any given number of vibrations per second, and, consequently, either a high or low pitched tone.

Mr. Cooke said he had seen a bell buoy off the coast of Cornwall, and also in the Mersey, near Liverpool, and heard sailors speak in favour of them.

Dr. E. J. Mann having expressed his high appreciation of the able manner in which the subject had been treated, said there was one remark in the paper which was of particular interest to him, viz., the peculiar way in which differences of sound often failed to be distinguished even when the sound itself was distinctly heard. He was now realising that fact himself. He had fortunately a keen and excellent hearing, which had served him well all his life, but latterly he had been told that he was getting deaf. He was rather surprised at this, and had been observing carefully to find what was the real fact. He found this peculiarity, that while he could hear sounds quite distinctly, even light sounds in the street, yet when his wife spoke to him he did not hear what she said. This seemed to show that the peculiar deafness which came over a man in advancing years was due to a want of power to distinguish sounds, and he believed that was the form in which the deafness of advancing life primarily showed itself. Every syllable uttered by Mr. Edwards he had heard most distinctly, but it sometimes happened elsewhere that he failed to distinguish a good deal of what was said.

Mr. W. H. Preece was rather surprised that no reference had been made in the paper to the proposal which he knew had been put before the Trinity House by Sir William Thomson, that a system based on that of telegraphy should be applied to the light-houses, so that they might speak in signals to the mariner in such a way, that wherever he might be he should know where he was. The map on the wall showed, that on entering the English Channel, there were three prominent points, the Lizard, the Start, and the Caskets; and it was perfectly clear that if each of those light-houses were supplied with a siren, which should shout, in stereotyped tones, "I am the Start," or "The Lizard," no one could possibly make a mistake, if he understood English,

though a Russian or Danish sailor might still be. To make this system still more universal, Sir Thomson proposed that every light-house should use its position in telegraphic language, which was instead of using common words, the name spelled out in high and low tones, or by in short sounds, or by dots and dashes, but by long and short sounds, which were to be graphically as clear and distinct as language. Every telegraph station in the kingdom had its particular name—Liverpool being Lv., Edinburgh, and so on—and these codes were used by telegraphists in communicating with each other instead of the full names. These codes were of precisely the same signals as were used by Trinity House, to distinguish their different light-houses. Trinity House's code was composed of a short sound, followed by an interval by four other short sounds. By this light-houses might be flashing out its name all night in this telegraphic language. And not only could it be done by means of light, but it could do so by means of sound. They only need arrange the fog-horns, or whistles, to repeat these signals after each of certain preconcerted way, so that whether by night, in clear weather or fog, a mariner who had learned this language, when he came within sight of a light-house, could not fail to know where he was. He knew there were serious objections to the application of this method to light-houses, but the Elder Brethren were not likely, in a light case, to set aside a plan proposed by so high an authority as William Thomson, and which had been previously adopted at Belfast and at some place on the Clyde, was, therefore, rather anxious to hear from Mr. Edwards what practical objections there were to the use of it, which, in the ears of any one trained to telegraphy, was as distinct as if each light-house were to be boldly out of the water and cry out its own name. With regard to Mr. Courtney's automatic buoy, he had to be in America some three or four years ago, was being tried off Sandy Hook, and although four or five miles from it, he heard a loud roar, wailing of a melancholy buffalo, which reached great distance, much to the annoyance of the land men, but to the great comfort of mariners. People not be selfish with regard to horns and the whistles of locomotives, which were the language used by them to communicate with the signalman. He could not say, from long experience, that the whistle was never used as it was required; the driver suffered from it as much as anyone else, but it was essential to the safety of the train. So with regard to fog-horns; they ought to be used in a system which secured the lives of so many people.

Mr. S. J. Mackie wished, in the first place, to give credit which was due to Sir Richard Collinson of being the first to apply explosive signals, for he was the first who sent up an explosive signal rocket. Some years ago, he was making his first attempt at explosive signalling, he received the greatest assistance and kindness from Sir Richard Collinson; he wished to add a few words on the merit of guns for signalling purposes. Guns required to be ordered, and from the time taken in loading could not be fired oftener than once in ten minutes, whereas cotton signals could be fired with certainty every minute; they could also be made, by using double single ones, to represent the dot and dash telegraphic code. There was also this great advantage that gun cotton could be used for what he called "ground signals." He preferred these for many reasons. You could regulate the height according to the height you wanted the sound to travel; and in some experiments made at Folkestone it was found, when the height above the pier was properly calculated, and the weather was stormy, and the passengers were lying on deck, it was distinctly heard by the crew at a distance of five miles. There was also this advantage

in the explosion was produced in the air alone : affect the stability of the ground or foundation of the lighthouse, as might be the case with firing repeatedly. Gun-cotton could be used in all, not being affected by damp, and the sound equally in all directions, when fired from the pier it was heard at Dover pier and at whilst the lighthouse at the back assumed the air in the town.

Mr. Edwards said he had been accustomed all his life to the English and St. George's Channels, and to mention one or two circumstances which the advantage of sound signals. The last bell he saw was one which he remembered being set by his late friend, Captain Pencock, and at the time he saw it, the sea was so calm that it did not move, and, consequently, the ball did not move.

That showed the advantage of having one of the automatic buoys. On another occasion, the English Channel on a calm summer's day in boat from Calais, they almost ran upon the South L, and had only just time to stop the vessel and turn to prevent running on the beach. If there was a loud siren blowing such a thing could not have happened; but this was about 20 years ago, before such were introduced. On another occasion, he was in a mail-boat going down the Thames, and the Red Sea in a severe snowstorm. It would be prudent not to go beyond the Nore, but so were the directors to get the new ship round to say that they ran the risk. The sea was soon so high, and they were in the greatest jeopardy, a most remarkable thing occurred. They desired a signal gun, and they had two nine-pounders on board. He himself saw the red-hot poker put to the deck, but neither he nor his friend by his side saw the sound of the gun. Whether the severe weather had their sense of hearing, or the snow prevented hearing the sound, he could not say. Happily, they were not by a man, and were soon got out of the sea. There were many difficulties in the way of putting Mr. William Thomson's suggestion, it was often difficult to see the glimmer of a light at all, and at all, the most-anchored of the mariner in time of fog on the coast.

The Chairman having complimented Mr. Edwards on his paper, and the perspicuity with which he had treated the subject was only a prolongation of the same intelligence, and fact which he showed when he was at the Chairman's side, day after day, during those memorable experiments which the Elder Brethren instituted at the South Foreland. The causes which obstructed sound in the atmosphere were mainly the wind, in the first instance; and secondly, the distance from what he had called acoustic clouds. Mr. Stokes's explanation of the influence of the wind, which had long been a perplexity to scientific men, was that, when an explosion occurred, the wave moved in all sides, so that it might be conceived as forming an arch over the earth's surface. For the sake of simplicity, we may take a typical case of that wave near the surface, and consider it might and vertical, it would move on horizontally, supposing nothing occurred to make it move up or down than the bottom, or vice versa. But in the case of the wind blowing in an opposite direction to the sound. The wind above was not so affected by the friction of the earth's surface as below, and, therefore, the wind above would quiver, and, consequently, the sound wave, through it would be tilted backwards, and in a slightly slanting direction. Now, the case of a sound wave was always at right angles to the face of the wave, and, therefore, according to Professor Stokes—and it had been since—when the wave was thus tilted

backwards by the wind, it gradually ascended, and passed over the head of the observer instead of coming to his ears. The acoustic clouds had been sufficiently described by Mr. Edwards, who, with himself, had made some remarkable observations upon them. They could be imitated. That room was now filled with acoustic clouds. From each mouth issued a column of warm air, and in passing from one portion of air to another of different temperature, or differently saturated, a certain portion of the sound wave was always reflected, and when this occurred extremely often, the sound was entirely wasted in these echoes which occurred in the air. Hence there might be invisible acoustic clouds, which behaved towards waves of sound as an ordinary cloud did towards waves of light. Various observations had been made upon the sound sent back from these invisible clouds, and he well remembered, one perfectly clear day, the surprise Mr. Edwards experienced when he heard the trumpet above them sending forth its powerful notes, and those notes coming back from the air in front of them. They seemed to come from the wide expanse of ocean, for there was nothing apparently to yield an echo. With regard to the experiments with gun-cotton, Mr. Edwards had mentioned the cause of its efficacy, which was this. If you pushed your hand through the air there was a tendency to produce a wave, but no sound was audible, because the air was so easily moved that there was none of that condensation and rarefaction behind, which was necessary to form a sound-wave; the air slipped away in front, and closed in behind as you moved your hand. Hence the importance of imparting a sharp shock to the air, in order that it might not thus exercise its mobility. This was what gun-cotton did, and that was the advantage of using gun-cotton, or the cotton powder to which Mr. Mackie had referred. In these matters, he believed a most important step had been justly referred to the Deputy-Master of Trinity House, the use of a rocket to carry a mass of gun-cotton 600 ft or 900 ft into the air, where it exploded. You could in that way get the sound into alcoves and bays, which were entirely shut off from a signal fired on the ground. If he dared speak further on the subject, he must say that it was pleasant to him to think of the days he spent beside that distinguished Arctic navigator, who was the inventor of this gun-cotton rocket. The manner in which he held on to those laborious experiments at the South Foreland, always at hand, commanding the vessel, moving her about, making observations with the sextant, he should never forget, for a better or nobler fellow labourer he never had. The subject Mr. Preese had brought forward had already occupied the attention of the Elder Brethren, but in dealing with sound it was not really so easy as one might be led to suppose, and he believed his remarks were chiefly addressed to light. But, no doubt, in the investigations which were about being made, no trouble or labour would be spared to get to the bottom of the question of differentiating one sound from another, and, if possible, arriving at the ideal state of things when a signal station should by means of its sound tell its name. That was the ideal to aim at, and the man who aimed at the sky, as Chesterfield said, would, probably, reach higher than the one who only threatens a tree. So, by aiming at the ideal Mr. Preese had put before them, the Elder Brethren might attain a degree of perfection, which otherwise they might not accomplish.

Mr. Edwards, in reply, said he would only refer to Mr. Preese's remarks. Mr. Preese said that every man who could speak English would be able to read the long and short sounds or lights signalled at sea; but he should have added—if he knew the Morse alphabet, which was itself a difficult thing to learn. He, as a distinguished telegraphist, of course had it at his fingers' ends, but it would not be so easy, say, to the master of a collier, who had not very much intelligence.

He knew how to navigate his vessel, but if he were put to analysing these sounds, he would be saying to his mate, "Bill, was that a long or a short one?" and, if he had not a watch, was he to fetch a clock from the cabin, and calculate how long a flash lasted, whether it was half a minute, or a quarter, or ten seconds. It was not reasonable to suppose that a captain of a collier, and many other men of even less mental calibre, could appreciate what Mr. Preece thought so easy.

The Chairman then proposed a vote of thanks to Mr. Edwards, which was carried unanimously.

## CORRESPONDENCE.

### PREVENTION OF FOG AND SMOKE.

It is with much satisfaction that I observe that Dr. Alfred Carpenter is to read a paper on this important subject before the Society on the 8th of December. At the Great Exhibition of 1862, Mr. George Devey, architect, and I, had a joint exhibit in connection with the subject. Since that time I have had occasional letters thereon in the pages of the *Journal*, and also in the *Times* newspaper, and it seems to me desirable to present your readers with a brief review of this matter as a preparation for the discussion which will follow the reading of Dr. Carpenter's paper.

A summary of the facts connected with this smoke question will be useful. There are about 550,000 houses in London furnished with about 5,000,000 chimneys. Of these chimneys, in winter, probably about 2,000,000 are daily vomiting visible smoke into our atmosphere. The calculation is, that this smoke by its effect on house paint, furniture, works of art, and body linen, costs the inhabitants of London £2,000,000 sterling a year. There are about 6,000,000 tons of coal consumed annually in London, of which it is calculated that about one-tenth part escapes as smoke, that is, unutilised carbon, the estimated value of which loss is £600,000 a year. The density of London smoke fogs arises from the presence of moisture in the air, which moisture is partly occasioned by the damp clay of the London basin, but chiefly by the large volume of river water meeting the sea water at a different temperature, and hence condensation of watery vapour takes place in the valley of the Thames, but particularly at the mouth of the river, and hence our great smoke fogs chiefly occur when the current of air comes from the east.

Paris not being in the proximity of large masses of water enjoys a comparatively dry and clear atmosphere. Our geographical and geological position cannot, of course, be altered, but we can do much, so far as the smoke nuisance is concerned, to amend our unhappy condition. Beyond the 2,000,000 house chimneys which in winter pollute our atmosphere, we have the chimneys of several thousand factories. With regard to the smoke produced by these factories, including bakeries, and I may add the chimneys of the kitchens of the West-end club-houses, the remedy is quite within the scope of the Smoke Nuisance Acts passed by Parliament. All that is required, is that these Acts be somewhat extended, and the machinery for carrying them into execution be simplified and rendered more peremptory.

At present, the police only can lodge complaints, and the practice is to give two warnings previous to issuing a summons before the magistrate, while the average fine inflicted does not exceed 30s. Were any two householders in the neighbourhood permitted to

inform, and were the average fine raised to £5, of which informers should receive one half, a few weeks could suffice to extinguish all factory smoke from London, because it is perfectly well known that by careful stoking, or by properly constructed furnaces, or by the use of smokeless fuel, such smoke can be abolished, and that to the pecuniary advantage of the manufacturer.

With regard to the abolition of the smoke proceeding from the two million household chimneys in operation in winter, the remedy is very much more difficult, but the smoke of ordinary fire-places could be abated or abolished by any of the following plans:—

1. By aggregating, say, every five hundred chimneys in one tall chimney, and then by a descending shower of water washing the soot into the sewer there to act as a deodoriser and disinfectant.

This method was proposed by myself and Mr. George Devey, by an exhibit at the Great Exhibition of 1862, but I readily abandon the plan as an interference with the freedom of street architecture, &c.

2. By the use of properly constructed grates—that is grates composed almost entirely of fire clay, with ornamental metal fronts—a great economy of fuel and more powerful combustion is obtained. Grates with perpendicular bars are said to be better than those with horizontal bars. If grates were all fitted with blowers, to be used on first lighting fires, much smoke would be prevented, as it is on first lighting, or mending fires, that most of the smoke is produced. Dr. Arnott's grate with a closed bottom, where the fire is lighted at the top and burns downwards, produces a less smoky fire than an ordinary iron grate, but the appearance of the fire is dull, and the ventilation of the room imperfect. Dr. Siemens' coke and gas grate, as described in *Nature*, 11th November, is an excellent grate, as I can testify from examination. It produces no smoke, and heats a room 7,200 cubic feet at a cost of 4d. for nine hours, notwithstanding that probably three-fourths of the heat produced is lost in the chimney.

3. By the use of coal-gas it is well known that cooking can be beneficially and economically managed in large establishments; but under the management of ordinary cooks, gas is an expensive cooking power. Were cooking by gas universal, as in summer kitchen fires only are in operation in our houses, the four months of the London season might be enjoyed in a perfectly smokeless atmosphere. Gas, as a heating power, can be economically used, provided the entire heat produced by its combustion is utilised, because, although gas, as compared with coal, cost for cost, is much inferior to the latter; yet, as three-fourths of the heat produced ascends the chimney, gas, under the above conditions, becomes cheaper than coal. If the demand for gas, for cooking and heating purposes, became much extended, the price of gas could be reduced, and also the price of coals, and thus the gas and coke fire might be cheaply produced.

4. By the exclusive use of anthracite and other smokeless coals, the smoke nuisance of London could be entirely abolished. It is stated that in Wales there are fields of smokeless coal, calculated at ten thousand million tons, equivalent to more than fifteen hundred years of our present London consumption of coal. This coal is perfectly adapted for all furnaces, and can be easily burned in all stoves and fire-clay grates, or in iron grates with blowers. Its freedom from sulphur is a further advantage, and in South Wales it is the usual fuel, both of cottages and towns, and where it is used there is no smoke. It is also used in New York and other towns of the Eastern States, and New York has a brilliant atmosphere, even in winter.

5. Lastly, I draw attention to the American method of warming houses, and as in America, the mercury often falls to zero, it is evident that the best heating apparatus becomes necessary to life. The American

is to heat the entire house from a furnace in the nt. The furnace is placed in a small chamber, h the external air is freely admitted; which air, ag heated by contact with the external surface of re, ascends through pipes to the top of the house, sing openings in these pipes into each chamber; ening being closed at pleasure. Thus it may be at is laid on like gas or water, to be used as re-

By this method the heat produced is, or might ily utilised, while a continual current of fresh, ir is admitted to the house. The hot chamber be constructed as a Turkish bath, and thus ly heat the entire house, but act as a most os and hygienic domestic arrangement. By g a house from a central fire, the dust and black of our ordinary fireplaces are avoided, and the e are saved the labour of carrying scuttles of coal. merican furnaces are chiefly of iron, and the duced is sometimes excessive. I should reed fire-clay stoves, with fire-clay brick flues, as Turkish baths. As this central fire has a furnace t, any kind of coal can be used with smokeless

he smoke produced by our factories could be at olished, and that with advantage to the manu- rs.

y the general use of gas, coke, and smokeless he smoke of London could be abolished, and thus ,000 saved to the inhabitants.

y cooking with gas and coke, and warming our y by a central furnace, the smoke of London could liated.

o secure these advantages even in part, the public, er with surveyors, architects, builders, and grate cturers, should act in unison with the producer , coke, and coals. But as the smoke nuisance of n is a rapidly increasing evil, Government may one nd it necessary to place the regulation of our tic hearths, and our gas, coke, and coal supplies, some central and paternal government.

GEORGE WYLD, M.D.

rest Cumberland-place,  
28 November, 1880.

is letter was in type before the reading of Dr. ster's paper, but was not published owing to want ee.]

time did not allow me to join in the discussion r. Carpenter's paper I now send you a few ts upon it. I have been writing about he fire-places for seventeen years past, at a great f time and money. If I have not succeeded ing a recognised public service, it is because e not received the assistance from the press which t to have had. They have been willing enough ive me money for advertisements, but have not he trouble to read and understand my books. re that the subject has come prominently forward, y hope that it will not be left till a thoroughly ing reform has been commenced.

ill first of all allude to the extraordinary and daring sions of carrying off smoke by some thousands y chimney shafts, with immense furnaces burning hem, supplied with the air and smoke from our s. Those who have brought forward such pro- ons can have no adequate conception of the ous cost, the overwhelming difficulties, and of the nty that, after all, the smoke would not be con- l, unless it was done in every separate fire-place.

w, as regards gas. I do not wish to prejudice, or anything that may prevent a fair consideration . Siemens's contrivance, but I must tell you that, than twenty-five years ago, my firm entered y on the manufacture of gas-stoves, and that we omed it entirely, in consequence of its bringing ntantly into collision with our customers. The

cost of gas was too great, and, in a large number of instances, the products of combustion did not pass effectually away by the chimney. These remarks do not apply to the use of gas for casual purposes, especially those of cookery.

Now, as regards anthracite coal. It is used in Wales, not from choice, but from necessity. It is nearer people's doors, and is very cheap. In using it here, we are asked to use a blower to make the fire burn cheerfully. By this you carry off the air of your room with great velocity, which air must be replaced from your doors or windows, or you will have a sluggish draught in the chimney itself, with a return of offensive products of combustion. If you propose to mix anthracite coal and bituminous coal in equal proportions, you must have machinery for breaking the coal into small pieces, and for mixing the two. You must also be prepared to pay the expenses of scientifically breaking and mixing. If this is not considered to afford a satisfactory solution, we must ask what may be done if we continue to use bituminous fuel. Dr. Arnott pointed out, many years ago, the proper way to use bituminous fuel was by introducing the fresh fuel below the fire instead of at top. A little consideration and observation will show us the utility of this. It is when fresh fuel is thrown on the top of a fire that a quantity of vapour, darkened by particles of carbon, escapes from the fire, and is what we call smoke. If, however, we introduce the fresh fuel below the fire, or burn a body of coal from the top downwards, like a torch or a candle, the vapour passes away invisibly through the hot stratum of coal, and the particles of carbon are consumed. Dr. Arnott's grate had certain defects, through which it never became popular. The objections were the sunk ashpit, the use of machinery, and the heavy appearance of the grate. I have not the slightest hesitation in saying that these objections may be effectually overcome, and, as regards matters of design or taste, Mr. Ernest Turner has kindly consented to give his valuable assistance.

Notwithstanding the objections, the grate has been highly appreciated for a long number of years by highly accomplished men. Sir William Gull has used it, and recommends it to his patients. His own grates were used by his predecessor, Dr. Todd. Sir Roderick Murchison used it with great satisfaction, and Mr. Thomas Burgoyne, a well-known solicitor, changed in the course of ten years the whole of the grates in two large houses in Stratford-place, and told me emphatically, that he had been repaid the cost of the grates by the saving of fuel, over and over again.

Now, as regards the kitchen department, we waste, undoubtedly, an enormous deal of fuel. We produce a large quantity of smoke, and we so fill our flues with soot that they require clearing every week. The matter, however, may be dealt with in a highly satisfactory manner, but only by following Count Rumford's advice, and avoiding the open fire altogether for nearly all the purposes of cooking. For the whole of the hot water required by a household we ought to use a closed fire and burn anthracite coal. This should enable us to have a warm bath at midnight without disturbing servants. For our ovens, used for baking, or ventilated when used for roasting, we should have a separate fire, never to be lighted except when absolutely required, and in this we may burn anthracite coal or coke. For our hot plate we may use gas or anthracite coal. In using gas, we must take care to provide means to carry off the fumes by the kitchen chimney, and in using anthracite coal we require a closed fire-place, and that the hot plate should be made in one piece, with only a round cover over the fire, so that we may get the full benefit of the laws of the conduction of heat, having no heated flame to depend upon.

I am sure that these arrangements can, with a little ingenuity, be combined in the basement of nearly all modern houses. It may be, however, that for very

small households an American stove, to burn coke or anthracite coal, and a little gas boiler, would meet all requirements, and give no smoke.

Now, can we reconcile our servants to this system? I believe we can, but we can only do it by training them. We must provide them somewhere in the basement, with an economical open fire-place, at which they can warm their fingers, and do little domestic offices; such as toasting bread, cooking a chop, boiling a kettle, &c., instead of using the gas hot-plate.

I have now given an outline of the way in which the smoke question, so far as domestic fires are concerned, may be effectually dealt with. We may not get rid of smoke entirely, but if we get rid of nineteen-twentieths, as we may unquestionably do, we shall do as much as can be expected, as long as we retain the use of open fires and bituminous fuel.

I will only add that I hope, after the close of this winter's discussion, to have the privilege of bringing forward the whole subject of the domestic uses of fuel, when I trust I may be able to deal with it more elaborately than at the present time.

FREDERICK EDWARDS, Jun.

Great Marlborough-street.

At the discussion on the prevention of smoke fogs in the metropolis, and in large towns generally, it was my intention not only to trace out, as far as possible, the true source of the evil, but to point out the limits within which the remedies obtainable would appear to lie. As it happened, however, I had only time enough to give a brief outline of the first topic, the claims of other speakers to a hearing not admitting of more than a general reference to the second branch of my intended communication to the Society. I wish now to supply that unavoidable omission.

As the report of the paper and speeches delivered at the meeting will show, I succeeded in proving, from the official returns of the annual consumption of coal in London, and from the admitted data of gas manufacture, that the quantity of water generated by the combustion of raw coal amounts daily to a mass equivalent to a rainfall of one-eighth of an inch over an area of 20 square miles; or, if a smaller surface be taken, of a quarter of an inch over an area of 10 square miles. This aqueous mass, converted into vapour in certain favourable states of the atmosphere as to pressure and temperature, &c., would obviously occupy an enormous volume, and would be sufficient to spread over the whole of London, if limited in height as Dr. Carpenter demonstrated it to be.

I alluded incidentally to the shameful waste of ammonia accompanying the general waste of fuel, due to imperfect combustion in our ordinary fire-grates. This waste will be best appreciated when I state that, assuming the gluten of wheat—the nourishing element in it to be on an average 26 per cent. of its weight and the nitrogen 15 per cent. of the gluten, 13 lbs. per ton of coal being the ammonia, the production of 8,000,000 of tons would be equivalent to 5,200,000 quarters of wheat, taking 60 lbs. as the weight of a bushel. In first quality wheat the gluten is 35 per cent., which would give even a larger number of quarters. This conclusion might seem to be irrelevant to the main question of the fog nuisance, but if we reflect that this important element of fertility is the invariable concomitant of the general waste of fuel, due to imperfect combustion, and withal, an element injurious to the respiratory organs, and to the mucus membrane, we shall perceive that it strengthens, under its double aspect, the claim of the public to a reformed system of heating their dwellings.

At this point it is proper to observe that the most perfect combustion of bituminous coal could do no more than remove the hydro-carbons in their gross and unconsumed state, the ammonia and the aqueous vapour in the purer fog still remaining unsubdued.

If the hot products of combustion were to be condensation through the tubes of a tubular boiler full of cold water they would be condensed, heating the water in passage, while the resulting liquid would pass to a receiver, thus collecting the ammonia present. If the boiler were to be constructed with two pipes, communicating with a cistern of water at the top of the house, the warm water would ascend, while cold was descending, until the temperature of both vessels should be the same. The hot water would be conducted from the cistern above by pipes, to the upper apartments of the house, and used for heating and other domestic purposes. This, it is needless to say, applies to only the better class of houses, manufactories, &c. The working classes, lodgers, and others who are restricted to the use of coke, or of anthracite on stoves suitable to their combustion. In this case coke must be manufactured somewhere, in or near London, or near the pit's mouth, and then the question naturally arises—"What would be done with the gas?" The answer to this is simple—"The application of the gas would be to heating purposes of all kinds, by means which should ensure perfect combustion, and utilise the heat of the products of combustion." It is implied that the ammonia would be collected in the cooking process yielding the gas. Iron works the gas could be used in cementing the ore preparatory to charging the blast furnace. A simple calculation determining the weight of iron reduced by the gas due to a ton of coals would satisfy most readers. I only indicate this process as an element of economy.

I now come to an application of both coke and anthracite coal to the production of carbonic oxide gas, which could be conveyed by pipes, like the present lighting gas, to every fire-grate in London. I advocate this with much hesitation, well knowing the fears and prejudices which I have to encounter. It is a deadly poison, but, so is carburetted hydrogen, a certain proportion to air of respiration, besides being explosive and dangerous to life as gunpowder, common with nitrogen, both gases asphyxiate; water as a true poison, or by deoxidising the blood, is equally fatal. But is not carbonic oxide, as is carbonic acid, at present evolved in great quantities, passing, with nitrogen, sulphurous acid, and carburetted hydrogen, up our chimneys, especially red hot grate full of coals?

More than this, it is to be noted that carbonic oxide would not be consumed like the present lighting gas in the midst of our apartments, by burners such as above our heads, and free, in case of escape, to mix with the air which we breathe. It would be burnt as it is at present—in the grate, with a current of heated products of combustion passing up the grate, and even if escaping unburned, being specifically heavier than air, it would ascend. With anything like a well-constructed and well-ordered apparatus, the gas led indirectly to the grate from without the walls, and its use would not be more frequent than at present from the incautious use of carburetted hydrogen gas burners. The heat given out by a grate filled with pumice stones, or balls of fire-clay, submitted to burning carbonic oxide, would be very intense, giving out, too, a bright light, and could be regulated to suit by the jets. There are two modes of generating gas from limestone or chalk, by passing its carbonic through red hot coke or anthracite coal, or by passing steam through the same heated fuel. I prefer the former, because when spent, the produce in lime can be sold to advantage.

But there is a second application to which I invite special attention. By slaking the quick-lime (above if spent steam be used for the purpose) in cylinders placed in large reservoirs of water, at least as much heat would be evolved as was originally employed

the carbonic acid. The water so heated could be used in well-fitted pipes to a great distance for houses, as well as for domestic purposes. The use of fuel thus attainable in the great city of London would be enormous.

object is to ventilate the above suggestions, in hope that their publication may lead to their adoption by that large class of ingenious and well-meaning habitually devoted to kindred objects, and competent judges of the merits of my plan. I trust that I have succeeded in proving that the thing was more than complete combustion is required.

F. C. KNOWLES.

18th Dec., 1880.

my interest some of the members of the Society to know that it is quite easy to burn a mixture of gas and coke in an ordinary domestic grate, without the expense of fitting Dr. Siemens's regenerative apparatus to it.

we done so for some time, and first described my plan in a letter to the Fog and Smoke Committee, 17th October last. Dr. Siemens first described my suggestion in a letter to the *Times*, dated 2nd Nov. A drawing and description of my grate is set in the *Sanitary Record* of 15th December; but my idea is that the whole thing consists in lining the grate with fire-brick, and introducing small gas jets upon the front of the grate, through perforations in the gas-pipe laid at the bottom of the grate in

we fitted an "experimental gas meter," by Messrs. & Co., to one of my grates, and carefully adjusted the coke supplied to it, and find that the cost is never more than one halfpenny per hour, which is not far from burning a mixture of gas and coke in Dr. Siemens's grate, as given by himself. I find the smokeless, convenient, and economical, but so pleasant in any manufacture, or sale of any article connected with it. I hope, for the sake of the people of London, that it may be extensively adopted, and any person who thinks of having it fitted to his house, is quite welcome to call and see mine.

COMING LYNCH, C.E.

London, Adelphi.

point was granted in 1873 to the Rev. Thomas Arnold, rector of Morton, near Manchester, for the purpose of warming dwelling-houses by the improved method of warming dwelling-houses by the buildings, economising fuel, burning slack, and the bulk of the refuse, improving draughts, and the smoke chimneys.

point consisted in closing in the space between the grate and the hearth by an iron plate, or back of an ash-pan, forming a chamber beneath the floor, thus preventing dry draught from the room below, so ventilating it; this air was controlled by a valve, which regulated the draught. In burning coal, a saving of 25 per cent. was effected, while with careful stoking, 45 to 50 per cent. was easily reached. With this stove, coke was a better fire than coal, as an intense glow or a big fire may be had as desired.

hundreds of the grates were fitted in the neighbourhood of Manchester, and satisfactorily; but through the means to work the invention (which also included the use of a sole manufacturer), the business was collapsed.

action may be applied to most grates by an workman.

THOMAS WOLFEHART.

Green-square, E.C.  
Nov 16th, 1880.

I was rather surprised to find an old popular error cropping up in Dr. Carpenter's interesting paper upon Fogs; and was the more surprised that it should occur there, because Dr. Carpenter has evidently made a careful study of the subject of fog. Near the bottom of the second column, on page 52, Dr. Carpenter observes, that the most curious effect of the fog "is the obliteration of sound, which prevents one from perceiving the approach of moving objects, until they are close upon you, and moving vehicles suddenly appear like ghosts upon the scene; a noise upon the top of a building is heard much more distinctly than one near the ground." He then goes on to remark, that where the fog was thickest, the sounds were most indistinct. Now, if there is one fact more certain than another about fog, I take it to be the fact that fog is rather a conductor of sound than an obstacle to it. This has been proved by the long-continued observations carried on by Dr. Tyndall on behalf of the Trinity House, and has been further verified by a series of experiments made by the same distinguished philosopher. It is now a received axiom that sound is not impeded by a homogeneous layer of air or fog, but that it is obstructed when it has to pass through layers of various density. It is also, I believe, accepted, that sounds are heard further in dense solid fog than they are in a clear day, when the air, though optically clear, is very likely to be acoustically impervious. It is curious that the error—for error it must be admitted to be—should be so deeply rooted. I have tried on one or two occasions, but in vain, to convince signalmen on a railway that they were able to hear as far in fog as on a clear day; but I have never succeeded in inducing them to believe me, or even to make careful observations after I had talked to them.

H. T. W.

[Since the above was written, the subject has been further elucidated by the paper read last Wednesday by Mr. Price Edwards, and by the remarks of the Chairman of the meeting, Dr. Tyndall.]

Now that strenuous exertions are being made to mitigate the evil of London smoke, it is but fair that some notice should be taken of the endeavours made more than two centuries ago, by a distinguished Englishman, with the same end in view. John Evelyn published, in 1661, his "Fumifugium, or the inconvenience of the Aer and Smoke of London dissipated," in which he proposed two presumed remedies. One was, the banishment of noxious trades (such as brewers, dyers, soap boilers, and lime burners) from London; and, the other, the encouragement of plantations. He particularly recommended the plantation of lime trees as an antidote to the evils of London smoke, and it is supposed that the trees in St. James's Park were planted there in consequence of this suggestion. In accounting for the origin of his book, Evelyn says, that while walking with Charles II. in Whitehall, his attention was attracted to the clouds of smoke that issued from chimneys close by Northumberland-house, and adds, that the king commanded him to draft a Bill for presentation to Parliament, by means of which the nuisance should be abated. The author subsequently conferred with the Attorney-General, but nothing came of the suggestion, in spite of its having been made by a king. "Fumifugium" was re-issued in 1772, when the editor referred in a preface to the smoke made by the York Buildings Waterworks; and, in 1822, an analysis of the tract appeared in the *Journal of Science, Literature, and the Arts* (vol. xii. p. 343).

X.

The following letter was addressed to Mr. E. Chadwick, C.B., Chairman of the meeting, on the 8th inst. :-

I regret that an engagement, already made, prevents my being present at the meeting of the Society

of Arts on the 8th inst., to hear the paper on smoke abatement in London. I may say that I am sure that the metropolitan gas companies would give cordial assistance in the matter, if from no higher than selfish reasons, because the employment of gas for the purposes of warming, ventilating, and cooking, as well as for motive power, would induce an increased consumption, the effect of which would be to add to our shareholders' profits, and, as under the existing sliding scale of price and dividend the companies are actually in partnership with the consumers, further reduction in the already low price of gas must needs follow.

The gas companies have, thus far, not had very much cause to thank the local authorities, whose object appears recently to have been to prevent the proper lighting of the streets, but you may take it from me that the use of coal gas is, at present, only in its infancy, and it not only can, but will be applied with as much success towards the object you have now in view, as the companies have already shown it to be capable of for the mere purposes of illumination.

J. PHILLIPS, Secretary.

The Gas Light and Coke Company,  
Horseferry-road, Westminster, S.W.,  
7th December, 1880."

### HOUSE-DRAINAGE TESTS.

The system of testing drains by the use of peppermint or Mitcham oil, as used by the Boston Board of Health, as explained at page 16, and by Mr. Innes, as per page 45, is rather indefinite, I consider, for general use. In this case one has only the sense of smell to be guided by, whereas by the smoke test the more definite sense of sight is added to that of smell. The sulphur which I use to raise the smell is also a good disinfectant. Sometimes there are people, too, who have "no noses," and who refuse to believe the smelling evidence as to the drains, &c., leaking, but when the smoke is seen pouring out they cannot get over that evidence. The smoke test is also the most practical one to apply when laying new drains. In the smoke tests I speak of, the smoke is blown into the pipe by means of a fanner. I have used this mode regularly for some years back.

W. P. BUCHAN.

21, Renfrew-street, Glasgow, 4th Dec., 1880.

It seems to me a pity to waste a good, honest, anti-spasmodic, like oil of peppermint, down soil-pipes, reversing the adage of putting the beggar on the gentleman. Instead of using "an ounce of the Mitcham oil for each house, that costs 2s. 6d.," I utilise the remainder fluid drawn from my gas carburetter, which, though not "like the sweet south that breathes upon a bank of violets," as a detective, will knock oil of peppermint into a cocked hat.

P. HINCKES BIRD.

1, Norfolk-square.

### CROYDON BOURNE FLOW.

The following letter from Mr. Baldwin Latham, M.I.C.E., F.G.S., appeared in the *Daily Chronicle*. It refers to the underground river that rises at certain times after a period of considerable rainfall:—

"Under the head of 'Local News from Croydon,' I find it stated in your issue of to-day, that, in the course of a few days, the Croydon Bourne will rise in Marden-park. As the author of the prediction of the rise of the Bourne in Croydon, will you allow me to state that, although Marden-park is, traditionally, the place in which the Bourne rises, the Bourne recently predicted by me will not rise here, and it is very improbable that it will flow at all this year in Marden-park. The predicted Bourne will commence as a small Bourne, flow very much lower down the valley than Marden-park, or immediately below the 'Rose and Crown,'

under Riddlesdown, and about 1,500 yards Kenley Railway Station, and will not commence flow until after December 11.

"These Bourne flows, which have for many a past troubled superstitious persons, have been upon to presage 'war, pestilence, and famine' there are numbers of instances where a Bourne flow accompanied great outbreaks of disease, as a case in the great epidemic of fever in Croydon broke out in the latter end of the year 1852; the Bourne flow was not the cause of this epidemic; the other hand, as a rule, the healthiest years are in which there is the largest quantity of water in our subterranean reservoirs, but generally the conditions, antecedent to a great Bourne flow, have been favourable to the development of fever and diseases.

"This occasion will make the fifth year in which I have predicted the date and volume of these my Bourne flows, and up to the present time each prediction has been verified, showing that the cause of these flows has been taken out of the region of conjecture placed within the range of scientific demonstration.

"The predicted Bourne will commence to flow at an earlier period than usual, and, in consequence, the probable future volume cannot be predicted with accuracy. Present indications show that it will little exceed the volume which occurred in the spring of 1878. If there be a large rainfall between the present time and the end of February the predicted Bourne may develop into a large flow and break out in Marden-park, but should be the case I should be able to predict its occurrence even in that locality before it occurred, as the one which broke out there in the early part of 1878. I am, Sir, yours faithfully,

"BALDWIN LATHAM.

## REFORM OF THE PATENT LAWS.

ouncil adopted the following Petition to  
e of Commons, at their meeting on Mon-  
inst.:—

RIGHT HONOURABLE THE COMMONS IN  
PARLIAMENT ASSEMBLED.

*umble Petition of the Council of the Society  
Manufactures, and Commerce, incorporated  
Charter,*

ITE,—

the Society is deeply interested in the  
w, and submits that it ought to be made  
s, as far as possible, to the progress of

the Arts, Manufactures, and Commerce of this  
country, so as to allow the inventions of the  
United Kingdom to compete fairly with those of  
all the world.

2. That the Society, in the years 1850, 1851, and  
1852, published reports on the Patent-law as then  
existing, and that those reports were instrumental  
in inducing Parliament and the Government to  
pass the Patent-law Amendment Act, 1852, which  
completely reformed the law.

3. That the effect of such reform has been greatly  
to stimulate invention, and has so increased  
the amounts derived from Patent fees, that they  
have now reached the sum of £180,000 a-year, of  
which only about £40,000 are expended in con-  
nection with the administration of the law, leaving  
£140,000 as a tax on the progress of invention.

4. That your petitioners are of opinion that the  
law still retains some antiquated fictions which  
should be abolished; that it should be greatly  
simplified; and that, as Patents relate to Arts,  
Manufactures, and Commerce, all matters connected  
with them should be administered by persons  
having knowledge of Arts, Manufactures, and  
Commerce, and not by legal functionaries, how-  
ever eminent.

5. That your petitioners desire to call the atten-  
tion of your Honourable House to the Patent  
Museum, which is in an unsafe, overcrowded,  
building, although it contains unique and valuable  
specimens of those early mechanical inventions  
which have revolutionised the Arts, Manufactures,  
and Commerce of the civilised world; that such  
Museum is quite unworthy of the Nation, and  
ought to be replaced by a suitable building, con-  
taining accommodation for a Reference Library.

Your petitioners, therefore, pray your Honour-  
able House to cause the present Patent-law to be  
amended, and its administration to be entrusted  
to the Lords of the Privy Council for Trade.

And your petitioners will ever pray.

Signed on behalf of the Council of the  
Society for the Encouragement of Arts,  
Manufactures, and Commerce,

H. TRUEMAN WOOD, *Secretary.*

The Council also appointed a Committee to  
draft a Bill for submission to the Government.

## PROCEEDINGS OF THE SOCIETY.

## CANTOR LECTURES.

SOME POINTS OF CONTACT BETWEEN  
THE SCIENTIFIC AND ARTISTIC ASPECTS  
OF POTTERY AND PORCELAIN."

By Prof. A. H. Church, M.A. Oxon., F.C.S.

LECTURE I.—DELIVERED MONDAY, NOVEMBER  
22, 1880.

*Terra-cotta, Bricks, Basaltes, Earthenware, and  
Unglazed Bodies in general.*

There are several opinions now current as to  
the effect of scientific knowledge upon the artistic  
value of the products of manufacture. Some  
persons argue that the evidence afforded by the

consummate beauty of certain Greek vases of the "period of perfection" will suffice to prove not only that a rational, an intimate, and an exhaustive knowledge of the chemistry and physics of ceramic materials and processes is not needed, but also that it is certain to end in what we may term artistic disease, and the death of true beauty. They deem that knowledge, full, exact, unbending, fetters the imagination, and crushes the poetry out of the handiwork of man. Quite on the other side are ranged the devotees of science. Science, say they, must be master. Nothing is satisfactory but mathematical precision. Not content with explaining, by means of all kinds of analytical processes, the causes of the beauty of any product of human skill, these rigid disciplinarians permit no departure from established rule. But, happily, there is a third, and, we trust, an increasing, group of persons concerned with manufactures, who take a broader view of the requirements of the day. They are prepared to welcome every kind of aid, from whatever quarter it may come. They call in the assistance of the chemist to analyse old materials and to search by synthesis for new. They appreciate highly the hereditary and traditional knowledge and skill which, rightly directed by a sense of fitness and beauty, have often in past times been alone sufficient to produce results of the highest excellence. But they will be always on their guard against—they will not permit—the dull uniformity and the complete stagnation consequent upon a mechanical routine, however perfect. They may temper the individual originality, which cannot bear to be always producing the same pot, just as the true painter will not endure the too easy labour of continually painting replicas, even of his best picture. But the judicious director or manager will be ever on the search for new developments in art. He will strive to learn from, rather than to imitate, the productions of other countries and other times. He will press into his service every improvement in machinery, in grinding and washing the raw materials, in enamels and glazes, in kilns and the use of fuel; but he will not allow the accuracy of his processes to exclude the charms of variety and tenderness in his products. He will recognise the importance of the fact that such a thing exists as harmony between the material and its decorative treatment, both as to form and colour. He will not insist upon the application to the finest egg-shell porcelain of designs characterised by rugged picturesqueness, nor will he diaper a piece of rough-marbled clay with delicate reticulations of coloured golds.

But, after all, is it not clear that, if an excellence of result that will bear the test of time is to be achieved, the highest art-knowledge and the highest art-power must be affiliated to our potteries? The perpetual experimenting (untrained as much of it was) of Wedgwood, would have led to no very adequate realisation in actual ceramic products, had not the sweet and careful neo-classical art of Flaxman been available. With wider research, with profounder insight, with more numerous and more varied available examples of excellence; in description more full—in explanation more exact, in analysis more thorough, in suggestion more fertile, in taste more eclectic—the spirit of to-day, if more exacting than the

spirit of yesterday, should at least make the attempt to secure, in some measure, that quality of rounded perfection which inspires our efforts, though, alas! too often only to condemn them. We enjoy greater and more varied opportunities of knowledge, and training, and execution, than Wedgwood, and we shall fail of our duty to ourselves and to our country, if we do not take full advantage of them.

Such views on the connection to be established between the sciences and the arts, which can be enlisted in the service of ceramic manufactures, have long been mine. Thirteen years ago, in an address to the Cirencester School of Art, I used similar language, dwelling with special emphasis upon the right use of the large resources which chemical knowledge bestows upon the art of pottery, and urging temperance in the employment of strong colours and showy glazes. These should be used to decorate and develop the beauty of fine contours and good forms, not to obscure them.

My special object in these lectures requires a few explanatory words. The general title of the course indicates its character, but not the limits which many causes combine to place upon my treatment of the subject which is to engage our attention. What then I propose doing in the present and subsequent lectures, is simply this—to note the relations existing between the chemical and physical qualities of some kinds of earthenware and china, pottery and porcelain, or whatever names we may use for these products, and their artistic qualities, as apprehended by the trained eye. On the one hand, I shall not attempt to offer instruction in practical potting, of which I know far too little for my own satisfaction; on the other hand, I shall make no pretence of scientific completeness in what I say on the chemistry and physics of my subject. From time to time circumstances have led me to analyse, or to examine microscopically, the raw materials and the finished products of certain ceramic wares, and I purpose dwelling upon the connections thus unravelled between texture and composition on the one side, and artistic effect on the other. Thus, it will happen that many important matters will not be so much as named, and that some trivial details will be thrust into places of undue importance.

As neither my knowledge nor your time would admit of a complete discussion of the large subject before us, you will, I trust, pardon the imperfections incidental to my treatment of relationships at once numerous and obscure. And now that I endeavour to place in orderly sequence some of the main features of to-night's subject, I feel perplexed by the difficulty of marshalling my facts. Perhaps my best plan will consist in first offerings kind of conspectus of the contact points on which I wish to dwell. We may set this down, then—

Physical Structure	} virtually inseparable
Chemical Composition	
	affect
	1. Form,
	2. Surface,
	3. Colour.

Form is the primary necessity of all good wares. If beauty of form be attained, the eye is satisfied; it demands nothing more. In the entire absence of

on, whether of surface gloss or of colour, it is felt. The satisfaction furnished by form may be examined critically with care, but I do not propose to consider this of the subject now. I want to draw your attention to the two questions of surface and colour. Unglazed wares are concerned, adding to them a few observations on peculiarities of pottery, which, though glazed, owes its lustre to the body rather than to the glaze. I am in order some of the specimens before me, which such products afford of physical and chemical qualities of their materials. Plasticity, insolubility, contractility, and chemical interaction, may be included amongst the qualities thus to be considered.

is a specimen of common brown earthenware of Japanese manufacture. Three hemispherical cups of different sizes have been attached, not thrown, by pressure to one another, in which their form has been modified by pressure and contact, exhibits at once plasticity and plasticity of the moist clay. An example is furnished by this Japanese ware, which, in lieu of a handle opposite to the rim, has two depressions for finger and thumb on opposite sides—depressions made in the clay without breaking the continuity of the fabric. True, such unsymmetrical cavities upon the grotesque; and so, when workers have knowledge utilised such capacities of the clay, they added two or more further depressions, seen in many vessels of Greek and Roman

ware, modelled from the cypress of Japan, the unchangeable character of a refractory material. Upon all the minute and intricate details of this ware, has rested for hours the molten surface of the sharpness of every original impression could have remained intact. Neither fusion nor fusion has occurred.

compactness attainable with unglazed bodies is fully shown by these specimens of earthenware, which were polished, partially on the outside and inside, on the lathe, to give a rich reddish brown hue, and bear as fine as the jasper and basalt wares of the East, which they antedate by fifty years or more. But this mode of achieving a fine surface is to be commended. It brings out no device, and though it does illustrate a physical property of this ware, intelligible under the microscope. At the high temperature employed in the manufacture of red ware, the alkaline matters have formed a slightly fusible silicious film, in which the clay of the paste is firmly held; the resultant texture approaches that of porcelain, and may be justly considered as such. Yet, on examining the extent of this ware, often of large size and common, one cannot help regretting that so much has been bestowed on this compact, but uninteresting, body—labour which might have been more profitably given towards development of the hidden beauties of some hard stone, such as agate or jasper.

Wares, similar to the Dresden "red china" which were made, at one time, to a large

extent in China, and, during the present century, in Japan. Here are half-a-dozen specimens, illustrating easier and more legitimate modes of decoration, than that originally devised by Böttcher. We notice upon these examples ornaments and devices worked in the unburnt ware. The methods employed are four, and we may characterize the several decorations as (1) incised; (2) inlaid; (3) onlaid, or applied; (4) impressed. Should the resources of these methods be deemed insufficient, the ware, after firing, may be adorned with coloured enamels; some beautiful examples of Chinese origin exhibit blue, green, and white enamels, which, by their surface lustre, as well as by their colour, contrast charmingly with the matt or half-dead ground. The so-called Mishima ware of Japan affords further illustrations of the inlaying of one clay with another, and recalls, in a measure, the chief characteristic of the *faience d'Oiron* or *Henri Deux* ware. In the East, as in Europe, the range of colours in the body and its ornaments included, besides many shades of red and brown, buff, drab, and yellow.

No ware made in England, save that of John Philip Elers (1693-1710) and of his imitators and successors, quite equalled the "Eastern red dry china," as Wedgwood called the Oriental fabric to which I have been just referring. Wedgwood's own attempts in this direction were not equal to Elers's work, in fineness of paste or tone of colour.

The red tint of the greater number of the wares which I have described brings us to the consideration of its cause. Iron here, as elsewhere in the products of art as well as of nature, is the cause. This metal exists in clays burnt or unburnt in at least six states of combination:—

1. Anhydrous sesquioxide—causing a red or pink colour.
2. Hydrated sesquioxide—yellow or brown.
3. Pyrites—grey or blue.
4. Glauconite—grey-green.
5. Ferric silicate—yellow, buff, or fawn.
6. Magnetic oxide—neutral grey.

But it is not a mere question of the presence of one of these, for often two or more in the same body influence its colour. Through different amounts as well as qualities of iron compounds are the resulting colours influenced—further effects being produced by the several undermentioned conditions or materials:—

- a. Heat of greater or less degree.
- b. An oxidising atmosphere during burning.
- c. A reducing atmosphere; or, carbonaceous matter in the ware.
- d. Presence of lime or magnesia.
- e. Presence of alkalies.
- f. Presence of very fine ferruginous particles.
- g. Presence of soluble alkaline and earthy salts.

By the consideration of the states in which the iron existed in the clay, and of the changes wrought by the conditions and materials just named, it is easy to explain and produce at will a very great variety of colour-effects in unglazed ferruginous pottery. Many examples illustrating this fact may be cited. Such are the buff and red terra-cottas of Watcombe, and those made at Copenhagen by Ipsen and Ahrends; the body and decorations of many Greek and Roman wares; the black ware once so abundantly manufactured in

Roman Britain; and a large variety of Japanese products, amongst which the mottled clays of the Imado and Banko wares should be particularly noted. But no better illustrations of the varied functions of iron in earthen bodies can be furnished than those which bricks supply. We have thin Roman bricks burnt right through, and completely oxidised; we have the thicker bricks of to-day, varying between brown and orange, according to their position in the kiln. Then there are the plum-coloured bricks of the Tudor times, and the orange-red of the close of the seventeenth and commencement of the eighteenth century. The sickly yellow bricks, blanched by added chalk, made from the London clay, are a good instance of the curious effect of lime upon ferric oxide, neutralising its redness, and even replacing it by a dull pale green. The Dutch, two centuries or more ago, made excellent impressed bricks, with good ornamental details; some are to be seen still at Walsingham and Ley. And the exquisite terra-cottas of the time of Donatello, still extant in Florence, show what forms of beauty can be realised in common and simple clay. It would be as well for me to draw attention here to the peculiar defective surface tint which some terra-cottas exhibit. If one portion has been more compressed than another, or if one part has dried first, there is great probability that the part so pressed or so dried, will be covered, after firing, with a firmly-attached film of irremovable pale-coloured silicate, formed by the union of calcareous and other soluble salts (present in the water moistening the clay) with silica in the body. You thus get a sickly pallor where it is not wanted, as on the cheeks; while lights appear on edges and in shadows, and distort the modelling.

Thus far, I have spoken chiefly of colour stains of earthenware bodies attributable to iron, and yet I have by no means exhausted the subject, for I have not even alluded to these agate wares of the eighteenth century, made at Staffordshire and at Apt. But I must, at least, mention the coloured glazes which Mr. G. Maw and the Campbell Tile Company use so successfully in their encaustic tiles. Here we have the oxides of cobalt, manganese, copper, and chromium tinting the unglazed clays throughout their substance, and yet, in most cases, not modifying the hardness of the body. One of Mr. G. Maw's specimens seems to owe its spangled touches of puce to the partial combination with the paste of minute fragments of pyrolusite.

Leaving for future consideration the characteristic capabilities of many other kinds of earthenware bodies, I may conclude the present discourse with a few words on the subject of texture. Many ingredients may be (and some have been) introduced into a paste or body, rather to influence its texture than its colour. The satiny aspect of wares containing abetiform minerals, though developed by a glaze, is perceptible without such aid. Laminated and acicular minerals and artificial compounds lend themselves more readily to this end than do substances presenting greater solidity. The difficulty which the association with the clays of dissimilar compounds involves, is due to the unequal expansion and contraction on being heated or cooled, which the different substances suffer. But the Japanese, in the specimens which I brought here to illustrate this matter, seem to have over-

come this difficulty, at least, to a considerable extent.

It would be wrong for me to conclude my lecture this evening, without special mention of the kindness with which my request for the loan of specimens has been met. With a single exception, to ask was to obtain. To Messrs. Mintons, of Stoke-upon-Trent, Messrs. G. Maw and Co., of Broseley, the Campbell Brick and Tile Company, and Messrs. Londres and Co., the extensive importers of Oriental wares in London-wall, I must express my large obligation for many of the illustrative examples to which I have been directing your attention to-night.

## MISCELLANEOUS.

### NOTES ON USEFUL PLANTS.

(From the Kew Report for 1879.)

The report on the Royal Gardens, Kew, for 1879, which has recently appeared, contains some notes on the introduction and acclimatisation of useful plants into India and the Colonies, which may be interesting to the readers of the *Journal*.

With regard to those important medicinal plants, the Cinchonas, Sir Joseph Hooker deals firstly with what are known as Columbian barks, namely, those producing the Calisaya of Santa Fé, and the hard Carthagena barks. Both of these are of an extremely valuable kind, and only a few plants remained at Kew at the close of the last year. One of these was sent to Jamaica, from whence the Superintendent of the Botanic Garden reports:—"Our specimen of Carthagena bark is in splendid condition. We have now seventeen well established cuttings, with promise of more." The remainder of the plants were sent to India, and a subsequent report from Calcutta says that they are doing well, and there is every probability that they will soon be successfully propagated.

Regarding the extended cultivation of the well-known species of Cinchona, *C. succirubra*, *C. officinalis*, and *C. micrantha*, reports are given from several countries. Thus, from Assam, Mr. Mann says, with respect to the small patches of Cinchona plantations below Nungklow, in the Khasia Hills:—

"*Cinchona officinalis* appears to be healthy, the other two species (*Cinchona succirubra* and *Cinchona micrantha*) all present a sickly appearance, and most of them have only a few leaves at the extremities of the branches. Both species flower sparingly and form no good seedpods. This condition of the plants is ascribed not so much to the climate and altitude as to the very steep slope and shallow surface soil resting on rock, which does not retain sufficient moisture to suit these plants. The plants of *Cinchona succirubra*, near Jurang, look very much better, and both altitude and situation, as well as the soil in that place, seem to be more suited to this species than in the Nungklow plantations."

From Burma, the report of Major Seaton is not very favourable on the prospects of Cinchona cultivation. The plantations seem to have been made so far back as 1879. He says:—

"All things considered, the Cinchona experiment does not promise well. The oldest trees dying off, and the trees of very small size flowering and fruiting freely, are only too sure signs that the tree finds itself in a site not adapted to its requirements." It appears, however, that a Ceylon planter has made inquiries about a grant of land in the neighbourhood. It is possible that with the technical knowledge as to the methods of cultivation of Cinchona, and of obtaining a speedy financial return from it, which have been worked out in Ceylon, a better fate may be put upon the experiment in Burma."

At Gaderif, near the frontier of Abyssinia, *Cinchona succirubra* is said to do well. In Ceylon, it is stated that—

"The enterprise of the planters, and the necessity of obtaining a speedy return for invested capital, has led to much more rapid

of harvesting the bark crop being adopted in this island the first commencement of the enterprise would have been possible. The following statement appeared in the *Observer* for September 12th, 1878:—"Over large areas it seems as if *Cinchona officinalis* came to maturity in four years, while if trees begin to show signs of canker or even two and a half years, the bark ought at once to be taken off such trees will pay well for the gathering. We to Messrs. Howard a specimen of bark from three and a half old trees. The verdict was, 'good marketable bark as usual.'"

**Jamaica, the Superintendent of the Botanic Garden:**—

"I had one of the *Cinchona* plantations in the establishment open an extensive instead of the glass propagating houses found here. I sowed the seed under thatched sheds and the plants into beds shaded by ferns. This is a simple system, which is universally adopted in Ceylon, but here I fear that the system of glass houses and propagation by cuttings has done much to frighten people in Ceylon here, and besides the Government plantations have been able to distribute more than a few hundred they had not enough for their own use. In a few years next planting season, I shall have 60,000 which I can supply, and by the end of the year, possibly 100,000. Unless the trees are planted thickly, however, the ground, as the planters say, the cost of manure £4 per acre per annum. By the third year the soil planted and well supplied, ought to cover the ground all subsequent weeding."

**Mauritius:**—

"*Eucalyptus* have grown but slowly. Few experiments made with the plants, owing to more pressing work in the forests at a greater altitude than that of the lowland, have not proved satisfactory, but it is hoped some growing this useful plant, which will give beneficial effect to be hit upon, only it must differ considerably from other countries."

**Singapore:**—

"*Cinchona* (Superintendent of the Botanic Gardens) reports:—"I am to grow this here have proved fruitless, but *Cinchona* and *Cinchona* *concolor* are likely to do well at a elevation in Perak."

**a from Tinnevely:**—

"*Cinchona* reports:—"A few plants were sent from the tinnevely in this district (1878), and the *Cinchona* *concolor* were put down at an elevation of about 5,000 feet, in a valley in the high forest, they have been left entirely to the mercy of the weather, the growth continues steadily with that of *Noddingia* or *Amorpha* on the hillside. During my last inspection I found one of the largest to be nearly 50 feet high, it had three large stems at about 10 feet from the base, the leaves having, it was said, been broken away when young."

"The cultivation of *Cinchona* in Sikkim, the of Dr. King, published in the *Journal* for September last, p. 509, is of a subsequent date to that in the Kew report."

"The subject of *Eucalyptus* planting, Sir Joseph reports as follows:—

"of species of this Australian genus are continually added supplied from Kew. The following nations represent the made in the cultivation in various parts of the world:—

1. *Mr. Oudart* reports:—"The *Eucalyptus* *globulus* is the fastest growing species cultivated in the Khid Hills, it is to it comes *Eucalyptus* *rostrata*."

2. *Dr. King* remarks:—"The *Eucalyptus* from Queensland is more hardy of success than the more southern species, planting of which in the plains of Bengal requires people a special manner."

3. *Mr. Macrae* reports:—"The *Eucalyptus* from Queensland is more hardy of success than the more southern species, planting of which in the plains of Bengal requires people a special manner."

4. *Mr. Macrae* reports:—"The *Eucalyptus* from Queensland is more hardy of success than the more southern species, planting of which in the plains of Bengal requires people a special manner."

5. *Mr. Macrae* reports:—"The *Eucalyptus* from Queensland is more hardy of success than the more southern species, planting of which in the plains of Bengal requires people a special manner."

6. *Mr. Macrae* reports:—"The *Eucalyptus* from Queensland is more hardy of success than the more southern species, planting of which in the plains of Bengal requires people a special manner."

7. *Mr. Macrae* reports:—"The *Eucalyptus* from Queensland is more hardy of success than the more southern species, planting of which in the plains of Bengal requires people a special manner."

"The healthy appearance of some of the kinds, and the rapid growth they are making are sufficient reasons for encouraging their extensive cultivation in India." This is in accordance with what is known of the climate of that (extreme-tropical) part of India.

**Singapore:**—*Mr. Marton* reports:—"When sown in situ they seem to thrive fairly well in Singapore, but do not appear to stand transplanting. *Eucalyptus* *globulus*, *E. rostrata*, and one or two other species are growing well in the nursery."

**London:**—*Dr. Kirk* informs me:—"The *Eucalyptus* *globulus* from Queensland is now in less than two years from seed about 15 feet high, with wide branches."

On the very important subject of fodder plants, the Kew authorities have a great deal of information, as the following extracts will show:—

**Guinea Grass** (*Pennisetum purpureum*).—This, it appears takes the place of all other fodder grasses in Dominica, as it is hardy and requires but little cultivation.

**Dr. Murray** says:—

"By keeping the heads down and a little manure occasionally, it may be cut down, crop after crop, for many years. I have had a Guinea grass piece treated in this way for full twenty years."

**Prickly Comfrey** (*Synphyllum peruvianum*).—From various trials that have been made, it has been shown that this plant, although of great utility as an early fodder crop in cool and temperate countries, is not adapted for cultivation in hot countries:—

**Madras:**—The Agri-Horticultural Society report:—"Experiments with Prickly Comfrey have failed, the plants which were in the gardens, though receiving rather more than their fair share of attention, having one by one perished."

**Bombay:**—*Mr. Duthie* reports:—"I do not believe that the conditions at Saharapur, as regards either climate or soil, are favourable for the profitable cultivation of this plant. At Chajuri it thrives fairly well. Three crops were taken during the year from 35 roots growing 3 feet apart. The average weight of each crop was 30 lbs."

**South Australia:**—*Dr. Schomburgk* reports from Adelaide:—"Prickly Comfrey has again had a thorough failure, and it is now a fact that this plant is of little use; at least, on the South Australian plains."

On the *Téouinté* (*Euchima laurina*), *Mr. Woodrow* reports as follows from Bombay:—

"*Euchima laurina* produced a heavy crop of fudge when treated as a garden plant, but not better than would be given by sugar-cane in the same circumstances. When treated as a field crop, under the same conditions as *Jowara*, the produce was inferior to that crop."

**Queensland:**—*Mr. Walter Hill* reports from Brisbane:—"The seeds received by me were duly planted, and grew both strong and healthy, flowering about the month of May. From the opportunity I have had of judging of its nutritive qualities, I am not of opinion that it can be grown to much advantage in this colony; the stalks appear to be too fibrous and hard to possess much nourishment. I shall, however, make further experiments."

**Bombay:**—*Mr. Duthie* reports:—"As far as cultivation is concerned, success has been complete. The majority were fine, healthy plants, and an abundant supply of excellent seed was produced."

**Singapore:**—*Mr. Marton* reports:—"This grass, although useful, does not bear out its reputation in the Straits. Large quantities of seeds have been distributed, but all accounts from the Native States state that it pays far better to grow maize, as the same ground that will grow *Téouinté* will produce excellent maize."

**South Australia:**—*Dr. Schomburgk* reports from Adelaide that, notwithstanding the disastrous drought of the early part of 1878, "the prevailing dryness did not injure the plants, showing not the slightest effect on their leaves, which preserved their healthy green, while the blades of the other grasses suffered materially."

At the Government garden, at Palmerston, in the Northern Territory, the growth of the *Euchima* has been surprising. In the course of five or six months the plants reached the height of 12 to 14 feet, and the stems on one plant numbered 55. The plants, after mowing down, grew again several feet in a few days. The matter delight in it in a fresh state also when dry. Undoubtedly, there is not a more prolific fodder plant known.

I can recommend it as a most valuable summer fodder plant in any dry climate, especially if it can be planted in a moist soil. The only drawback with us will be that the ripening of the seed crop will be problematical, as early frosts will kill the plant."

The most recently introduced fodder plant is known as the *Tageanate* (*Cytisus prostratus* var.).

"It is a shrub indigenous to the Canaries, the leafy branches of which are said to be a useful fodder. It requires a light dry soil, and is rather intolerant of frost in winter. The plants should be planted 4 to 10 feet apart, may be cut two or three times a year, and will last 10 to 20 years. Thirty-five pounds of fresh-cut *Tageanate* mixed with 50 lbs. of chopped straw is said to be sufficient for the daily nourishment of a horse or cow. The seed,

to very slow in germinating. The seed was pretty widely distributed from Kew. It is too soon to expect the results of trials at present.

**MADRAS.**—Most of the seedlings died off after germination. Colonel Grant reports at commencement of present year:—"At present only two or three are looking healthy, and from them I should think very little fodder could ever be obtained."

**ROUTE AUSTRALIA.** Dr Schomburgk reports from Adelaide:—"The seeds were sown, and all came up. The growth of the plant is vigorous, some of the plants having reached 2 to 3 feet, looking healthy, not in the slightest degree affected by the severe dry weather we have had to contend with. I have many plants for distribution."

The supply of India-rubber, or Caoutchouc, is a question that has of late years occupied the attention of commercial as well as scientific men. It has received a good deal of attention at Kew, as the following extracts from reports from various parts of the world will show:—

1. **CANTILLAS**—SINGAPORE.—Mr Merton reports:—"The plants of *Hevea* and *Cassia* in the gardens are now large plants, but hitherto propagation from the strong growths they are making seems rather difficult, whereas they used to propagate freely from the weak wood produced while in pots."

2. **CHANGA BERAP** (Moulouk Gharu).—BURMA.—Major Sutton reports:—"A quantity of seed of this India-rubber tree was sown during the latter part of the season from the Botanical Gardens, Prome, Ceylon, and at the request of Dr Thwaites, an intelligent lad was deputed to Ceylon to receive instructions in the cultivation of India-rubber plants."

**CALCUTTA.** Dr King reports:—"The Ceara rubber promises to grow well in Calcutta. The seedlings received from Kew have thriven vigorously, and some of them are now 10 feet high. The Director of the Botanic Garden in Ceylon, having at the request of the Secretary of State for India, undertaken the propagation of this species, a quantity of seeds of it were distributed by him to Indian officers during the year. Supplies were, I understand, sent to the Conservator of Forests in Burma, and Amoy, and to the Inspector-General of Forests for Madras. A large supply was received at this garden, and a thousand seeds were sent, at the request of the Conservator of Forests for Bengal to the officer in charge of the forest plantation near Chittagong. The seeds received have been begun to germinate, and I expect before long to be in a position to issue supplies of seedlings for trial in different parts of the country. The plant appears to thrive very well in Upper India, and if the quality of rubber yielded by it in this country turns out to be good, its introduction may prove of much importance."

**SINGAPORE.** Mr Merton reports:—"Ceara Berap rubber must be omitted from the list of rubbers adapted to the climate of the Malay Peninsula, as it has invariably rotted off during continual wet weather."

**SARAWAK.**—Dr Kirk informs me that with him the Ceara rubber yields most abundantly, but the seeds are slow to germinate.

3. **HAVRA**—BURMA.—Major Sutton reports:—"At Mergui eight *Para* India-rubber trees, the survivors of the batch of seedlings received from Dr King in 1877, continue to do well in the office compound, and vary in height from 8 feet to 20 feet. They are large enough to admit of a considerable number of cuttings being taken from them."

**CALCUTTA.** Dr King reports:—"Para rubber, of which 14 plants were alive in the garden at the date of last report, continues to be as disappointing as ever. Most of these 14 plants are still alive, but they have not grown much, and it is quite clear to me that it is vain to hope that this species can ever be cultivated to profit in this part of India. Plants may be raised into growing in conservatories, but the species is by far too thoroughly tropical to withstand without protection the vicissitudes of the climate of Northern India. As I have before reported, I believe it is useless to try it anywhere in India, except in the south of Burma or the Andamans, and perhaps in Malacca. I learn from Dr Thwaites that in the Botanic Garden at Prome, in Ceylon, there are plants of *Hevea* of about 20 feet high, and that these are of the same age as the plants here, the highest of which is barely 5 feet in height."

**JAMAICA.**—Mr Jemman reported:—"I regret to say that there are only two plants of the Para rubber in the garden, one which I brought with me, and which is now a vigorous young tree 10 feet high, the other, the only one saved out of a case of 18 plants sent from Kew Gardens over two years ago, but which unfortunately on its arrival in Kingston was locked up in the Customs house for over a fortnight, to the influence of which, after the voyage, all but the one succumbed. The atmospheric conditions of this district appear favourably adapted to the successful cultivation of the Para rubber."

**SARAWAK.**—Dr Kirk states:—"The Para rubber is a less quick grower than the Ceara, and does not branch. It is 10 feet high."

Like India-rubber, Liberian coffee, about which so much was written and expected a few years since from its introduction and acclimatization into many of the British Colonies, has received a considerable amount of attention in the present report. In Burma it is said to

be thriving, and showing signs of flowering, as is hoped some opinion of the economic value of coffee may soon be known.

From Dominica, the late Dr. Imray follows:—

"I am glad to say that the Liberian coffee cultivation has fairly commenced as established in this island. Healthy, luxuriant trees on my small plantation, with berries on many of them, afford sufficient evidence of it being congenial to the plant. The cultivation is now only awaiting extension by others taking it up. I have thousands of seedlings planted out in the open, and thrive best a good many seedlings, however, by putting them, too small. To ensure their staying they should be sown before they are transferred to the soil. Protection, kind or other is also advisable at first, as well from the rays of the mid-day sun as from strong winds. When free and growing, the plants are hardy enough, and will to deal of exposure and neglect."

Dr Imray further remarks on the coffee-land of Dominica (*Coffea arabica*), which is now being cleared off the old *Coffea arabica* but which it was hoped would not find a rest on the new plants, that it really had attacked it in their very young state, and only on the early leaves. The leaves were cleared by hilling it and brushing off the chrysalis wherever it appeared after this the seedlings steadily increased, throwing out fresh leaves, after which most were planted out in the field, and were thick with not a speck of the blight on them. Dr Imray says:—

"This, however, is not the only attempt the insect has made to footing on the Liberian coffee. On carefully examining large trees some six or eight months ago, a few leaves were where the insect really had established itself, but in a manner. Some of the larvae were lively enough, but all small and weak, and the skeletons, if I may so speak of them, were found in the brown patches of the leaf, when and under which were separated. Very few were observed, and these were smaller than usual."

This report from Dominica, which is given in the Kew report, concludes with advice as to the absolute necessity of protecting the seedlings from the ravages of the white fly, without which protection few of the plants will be saved.

In Jamaica it seems there is a great demand for this kind of coffee, but attempt part of private persons to import other plants have failed. The plants, however, in the Botanic Garden, have ripened their seeds, which have been sown to increase the stock.

From Seychelles, Mr. E. S. Salmon, the Commissioner, writes:—

"About 100 plants of Liberian coffee—mostly raised by me—have been planted at Mahé Island, at elevation from the shore to 1,000 feet above sea-level. It is apparently so far, in the open without shade. One of elevation of about 300 feet, without any shade and granite rock giving out considerable heat, has about looking flowers on it. This plant is 18 months old."

From Singapore:—

Mr Merton reports:—"The Arabian coffee here is attacked by the disease (*Hemileia vastatrix*), which has so far been able to supply seeds for planting in Java. The Liberian coffee has not yet shown any signs of attack, although some Java plants have been raised here on the younger parts of the branches." (They have no connection with the disease.) "The species is very impatient of deficient drainage. The plants raised from Kew in May 1878, are now bearing light hundred fruits from our plants have been sent to Mount Hill Ponnang, and sent to Penang. Very reports have been received from the Native States regarding the plants of this species there, and there is no doubt that the Liberian coffee has found a congenial soil in the Malay Peninsula and adjacent islands, and its future cultivation may now be left to planters."

In Queensland, Liberian coffee is said to have been thoroughly established on the Herbert river, promises to attain complete success; while from the plants are reported to be in flower.

a subject of mahogany cultivation in the Old Sir Joseph Hooker writes as follows:—

It may be regarded as an accepted success. The tree is a native of India and in Ceylon, and in the latter a local demand for the wood. In this country new demand for it, one of the most recent being for the lining of railway carriages instead of teak, which is now only used for ship building. It is not easy to see any valid objection to the cultivation of a tree, the timber of which admits of use for a variety of purposes, and the growth of which is attended with little difficulty. As late as the Government of Bengal was adverse to mahogany plantations. The plan is now, however, been modified, and in his despatch Mr. Brandis, the Inspector-General of Forests, speaks of the trees which are cultivated by way of experiment, mahogany is the most important, and its success is anticipated, though it is too early yet to form final conclusions. Mahogany is also cultivated as an export to Europe and the Chittagong district of Bengal. The Government have a large well near Calcutta, and every effort should be made to increase it in those forest districts where climate and soil are favourable.

In Banky, Berma, Saharanpore, and Singapore seeds have been received of the cultivation mahogany, while in Queensland, seeds have been sent for sowing.

In the lead of "Food Products," attention is drawn to the desire of the Indian Government to introduce *chestnut*, a South American plant, productive of a root. A reference is also made to the use of chestnut as an article of food in the Apennines. Made from chestnut-flour which had been presented to the Kew Museum were found upon analysis to contain over 40 per cent. of a matter soluble in pure water. Professor Brandis, therefore, that chestnut-flour should be regarded as a valuable article, and suitable for children's food. A great deal of consideration is given to vegetable substances suitable for paper-making, besides useful and ornamental woods. The length of the article, however, precludes any detailed notice of them.

#### INTERNATIONAL WOOL EXHIBITION FOR 1881.

This report on the American textile industries which has been received from the Foreign Directors of the Crystal Palace.

The State of the City of Philadelphia is very interesting. One thousand mills are kept running on the Schuylkill, employing over 100,000 persons, and producing thirty-one millions sterling of woolen, cotton, and silk manufactures per annum. The wool for manufacture in Philadelphia and its vicinity, for the year ending April 1st, 1880, was 1,000,000 lbs., and the production of manufactures, of fine woolen and worsted yarns, carpets (and wool), clothing, blankets and fibrous manufactures and knitted goods, amounted to \$100. The wool production in the United States is 200,000,000 lbs., and the manufacture thereof is valued in value to one dollar per pound of wool. The importation of wool is from 30,000,000 lbs. to 1,000,000 lbs. Thus there is a manufactured product from the wool growth and importation of 200 for the United States.

The consumption of cotton in the manufactures of the Republic is equally remarkable. About one-third of the American crop is consumed in Pennsylvania, 1,000,000 bales of the annual crop having been spun by the Philadelphia spinners. Of the 570, which was 5,200,000 bales, the exports 4,220 bales (up to August 25th, 1880), and the consumption in America, 1,125,000 bales. The crop of so far as the returns of the gathering have amounted to 4,700,000 bales, which, at 50 cts. gives up a value of \$235,000,000. One-fourth

of this product, manufactured in Philadelphia, shows an industrial total of \$13,320,000. The wool production for 1880, is estimated at 300,000,000 lbs., at a value of \$1,875,000, and the exportation of 65,000,000 lbs., valued at \$406,200, added thereto, give a stock for manufacture in the States, equal to \$62,000,000 of manufactured products thereof.

The manufacture of three textile articles in the United States can safely be placed thus for the year 1880:—

	Dollars.	£.
Cotton ....	250,000,000	52,000,000
Woolens ....	300,000,000	62,000,000
Silks ....	30,000,000	6,200,000

The leading American manufacturers have expressed their willingness to take a prominent part in the forthcoming Exhibition, by showing wool, woollen manufactures, and machinery.

A large number of applications have also been received from British engineers and machinists for space to exhibit machinery in motion, and a committee of advice, consisting of official representatives of the Colonies, and foreign States, and gentlemen interested in International Exhibitions, has been formed.

#### TECHNICAL MUSEUMS.

A paper was read by Mr. Alderman W. H. Bailey, on "Technical Museums and Libraries," at a late meeting of the Scientific and Mechanical Society, Manchester. He said:—"If it be proper to establish free libraries for the benefit of the people in order that general knowledge may be acquired, it seems but reasonable that if it can be shown that there are certain trades on which the bulk of the people of a town are dependent for bread, and that full knowledge of those trades can only be imparted by means of models and drawings, that it is quite as legitimate to have free trade or technical museums as free libraries; the sole object being in both cases to increase the prosperity of those who pay the public rates. Foreign competition is becoming keener every day, and we must recollect with all seriousness that we have not always been the leaders in manufactures; indeed, before the invention of the steam-engine it would be difficult to name any great industry in which we were superior to other nations. The Dutch, the Spaniards, and the French and Italians were infinitely superior to us, and when all the world become proprietors of steam-engines, which is an exaggerated way to put the question, only those who can use the forces of Nature with the highest wisdom will be able to be first in the race. To the members of a Society like this it requires very little argument to illustrate the value of models and drawings over mere descriptions of machinery or processes. Our great inventors at the commencement of this century have nearly all been men of ancestral power—some call it natural ability in contradistinction to that ability obtained by education—and by that high skill called culture, these men, not having much to do, made single great discoveries. I say this because there exists a popular delusion that inventors very often are lucky guess-work men, who have been accidentally successful. My experience of men who have risen to positions as foremen and managers is that they have their positions because of their integrity, industry, and, to use the phrase again, natural ability. This class of leaders in our works are the very pick of the working classes, who have risen to their positions by reason of the qualities I have named, and it is for such who thirst for knowledge, as I know they do, and for young men who wish to aspire to similar positions, that I would advocate the establishment of technical museums. Now, what is wanted is a

museum in which first principles can be illustrated by means of models and sectional drawings. Let me speak with some diffidence, when I recommend that the cases of stuffed birds which exists in our museums be removed, and that their places be filled with objects of greater interest to those engaged in the trade of the district." The reader of the paper proceeded to state that in his opinion, the museum should consist of models as well as books, that it should be a technical museum and library, the models should be of interest to those engaged in the trade of the district, and each district would of course require a different style of museum. One at Halifax would be different to one at Bolton. The various industries, silk, cotton, flax, wool, being too vast for one museum, it would be less costly and more beneficial to let each have its speciality. The science examinations, the Whitworth scholarships, and the whole educational work of the country all do good work, indeed, far better work than had ever been done in this country before, but a great deal yet remains to be accomplished in every direction.

### COLOUR RELATIONS OF METALS.

In a paper on the colour relations of copper, nickel, cobalt, iron, manganese, and chromium, lately read before the Chemical Society, Mr. T. Bayley records some remarkable relations between solutions of these metals. It appears that iron, cobalt, and copper form a natural colour group, for if solutions of their sulphates are mixed together in the proportions of 20 parts of copper, 7 of iron, and 6 of cobalt, the resulting liquid is free from colour, but is grey and partially opaque. It follows from this that a mixture of any two of these elements is complementary to the third, if the above portions are maintained. Thus a solution of cobalt (pink) is complementary to a mixture of iron and copper (bluish green); a solution of iron (yellow) to a mixture of copper and cobalt (violet); and a solution of copper (blue) to a mixture of iron and cobalt (red). But, as Mr. Bayley shows, a solution of copper is exactly complementary to the red reflection from copper, and a polished plate of this metal viewed through a solution of copper salt of a certain thickness is silver white. As a further consequence, it follows that a mixture of iron (7 parts) and cobalt (6 parts) is identical in colour with a plate of copper. The resemblance is so striking that a silver or platinum vessel covered to the proper depth with such a solution is indistinguishable from copper.

There is a curious fact regarding nickel also worthy of attention. This metal forms solutions, which can be exactly simulated by a mixture of iron and copper solutions; but this mixture contains more iron than that which is complementary to cobalt. Nickel solutions are almost complementary to cobalt solutions, but they transmit an excess of yellow light. Now the atomic weight of nickel is very nearly the mean of the atomic weight of iron and copper, but it is a little lower, that is, nearer to iron. There is thus a perfect analogy between the atomic weights and the colour properties in this case. This analogy is even more general, for Mr. Bayley states that in the case of iron, cobalt, and copper, the mean wave length of the light absorbed is proportional to the atomic weight. The specific chromatic power of the metals varies, being least for copper. The specific chromatic power increases with the affinity of the metal for oxygen. Chromium forms three kinds of salts. Pink salts, identical in colour with the cobalt salts; blue salts, identical in colour with copper salts; and green salts, complementary to the red salts.

Manganese, in like manner, forms more than one kind of salt. The red salts of manganese are identical in colour with the cobalt salts, and with the red chromium

salts. The salts of chromium and manganese, as to the author, are with difficulty attainable in of chromatic purity. He thinks these properties metals lead up to some very interesting consid-

### PRODUCTION OF BRICK TEA IN HAN

The Commissioner of Customs at Hankow that the importance of the brick tea trade is increasing, and the demand becoming greater supply. The employment of steam machinery pressing the bricks has proved in every way success, the steam-pressed brick being much finished than that produced by hand, and more compact and firm, withstanding the difficulties better, and ultimately arriving at its destination little, if any the worse, for its journey. With method, the bricks, from insufficient pressure, were liable to chip and crumble at the edges; great stress is laid on the perfect appearance of brick by the Siberians, it can be easily understood a hard, sharply defined brick would at once be preferred. With both methods of manufacture, tea there is a drawback, and a serious one—the ing of the dust by steam, which robs it of fragrance. To remedy this defect a firm has fitted an hydraulic press, which turns out small corner-shaped cakes, weighing a quarter of a pound, retaining the original aroma in all its freshness. The Commissioner, has not, says the Commissioner, been sufficient to ascertain whether the compressed tea will succeed or not, but samples sent to Siberia have favourably reported on; and as the improved ordinary brick was so quickly recognised, it is that similar popularity will attend the latest methods. The two kinds will probably run side by side in friendly competition, as the brick will keep its position for use among the masses, and the compressed tea will become popular amongst the better class if really fine dust be employed in its manufacture, from its portableness and cheapness, to take the place of the leaf tea at present sent overland from Shansi. The following is the method of producing the brick tea. There are at present six factories in Hankow, in three of which boilers are either for steaming the tea, or both for that and furnishing power for pressing. The dust which brick tea is made comes principally from Ningohow in Kiangsi, and Tsung-yang and Lou-tung, in Hupeh, and varies both in fineness and cost, according as it belongs to the first, second, or third crop. From four to ten taels is the average price. The first operation is to sift the dust and reject sand and rubbish contained in it, usually amounting to about 5 per cent. It is then placed in a winnowing machine having three different sized sieve-troughs corresponding, and passed into a basket residue which is too coarse to pass any of the dust is taken out and trodden until it is reduced to the consistency, when it is placed in iron pans over a coal fire until it is sufficiently brittle, when it is taken to be winnowed, and this operation is repeated until all has been sifted to the requisite fineness. Three sizes are produced, the coarsest being employed to constitute the brick, the finest dust is only used as a facing. The dust, when properly sifted, the next step is to press for pressing, and this is done by exposing it to action of steam for three minutes, and it is then steaming that robs brick tea of its scent and, and for which a remedy is eagerly sought. The fashioned apparatus of native design consists of iron boilers heated by charcoal, and having over which are fitted with rattan covers. When the dust is to be stamped, it is spread out on a sheet of

aced over the boiler and covered up; but with proved European apparatus the dust is simply to iron boxes and the steam then passed through.

After having been sufficiently steamed to make sure, the dust is put into a strong wooden mould with a moveable cover of which the trade mark of the G<sup>d</sup> or firm is engraved, so as to leave the corresponding impression on the brick) and firmly wedged. It is then pressed and placed on one side for some hours to cool. Each brick should weigh one lb., and all those that do not come up to the proper standard of weight, or are defective in any way, are shot and re-made. For this purpose they are taken to a mill, constructed of two heavy circular stones, moved by a horizontal wooden bar, and working around where the condemned bricks are thrown, crushed as the wheels pass over them. Having become dust, the operation already described is, in details repeated. The hand press turns out sixty to a day, with 25 per cent. of failure bricks, while the steam press produces eighty baskets a day, with 5 per cent. of bad work, and the saving, by the system of the improved machinery, amounts to one basket, or, according to the above stated out-turn, thirty-six going to a basket when packed for sale a day, or about £20 sterling. The bricks found correct in weight and free from defects are stored in a drying-room for a week, when they are carefully sorted separately in paper, and packed in bamboo baskets containing sixty-four bricks each. Green brick made in the same manner, but of leaf, not dust, the bricks are larger, weighing two pounds and a half, thirty-six going to a basket when packed for sale. During the past year only two factories in the district, at Tung-yang and Yang-lout'ung, were working, and it is expected that in a short time, the whole trade will be transferred to Hankow, to the advantage of its position as a commercial centre, and to the mutual interest of those connected with it. In regard to brick tea proper, there is also another kind called "medicine tea," which is composed of leaf and stalks, mixed with various kinds of medicinal herbs, and packed in bundles weighing sixty catties. It is valued at five taels per picul, and in view of the cost of transhipment to Central Asia and India, instead of as hitherto from Shansi, proving hardly low, it is expected that the trade will receive a great impetus.

Regarding the immense quantities of brick tea now being sent to Tientsin for transport overland, it is both difficult and more expensive to obtain sufficient quantities, than it was a year ago, and it is anticipated that the sea and river route via Tientsin and the Amoor will be substituted as a necessary consequence of the great magnitude of the trade.

## CORRESPONDENCE

### NATIONAL INDUSTRIAL CONGRESS, BRUSSELS.

In your recent number of your *Journal*, I find the report of the Congress of Industry and Commerce (Vol. 29). In this report, which I consider very good, you omit to mention what led to the important result I put forward, and which was unanimously adopted. The following is taken out of the *Echo du Parlement*, which shows what took place on the 9th September.

Springard said that the question of an industrial teaching was one most interesting for the people, and was in close connection with teaching in general. What the German speaker had

asked, could only be resolved in a Congress where questions of general teaching as well as trade-arts were discussed. In all civilised countries of Europe, we find a succession of studies through which learners are bound to go to obtain a good education.

"Is the case similar in the teaching of industrial arts? Indeed, a great difficulty arises here. Some industries can not be taught; for instance, the working of coal pits and the manufacturing of iron. In these cases, it would be desirable that such large establishments should be open to students, through some general concert between the employers; some of them have so been opened. There are also the different manufacturing industries, in which it is necessary to join to the workshop a school of apprentices. Practical people ought to make the distinction, and the men of industry are the best judges. But should they fail to fulfil their part, the State would then but fulfil its duty by opening industrial schools.

"The Government would have to recognise that industrial teaching is a question of public utility, and that, in case a part of the country requires it, a subsidy ought to be voted for such new schools. The industrial schools, with the workshops in connection, ought to be considered as objects of public utility."

Will you insert these few lines in your next number. Your previous report will gain in precision, and you will oblige me, as I admit I attach a great value to the question of industrial teaching.

PIERRE SPILGARD,

Membre du Conseil Provincial du Brabant.

5, Place de l'Industrie, Brussels.

### SIGNALLING BY MEANS OF SOUND.

In my paper on the above subject, I have unintentionally done an injustice to Professor F. H. Holmes, by giving the credit of certain new forms and applications of siren instruments to Messrs. Sautter, Lemonnier and Co., of Paris (see p. 75). I beg leave, therefore, to be allowed to correct my error, and to express my regret that the source from which I obtained the particulars in question was inaccurate.

Professor Holmes now informs me that Messrs. Sautter, Lemonnier and Co. have simply manufactured instruments from his designs; that the double siren is his invention, and was patented by him in 1875; that the siren arrangement for locomotives is also his design, and was placed in Messrs. Sautter's hands for manufacture.

I am anxious for the insertion of this letter, as I should indeed be sorry that a gentleman who has given so much attention to the subject, and worked so meritoriously in connection with it, should, in any way, suffer from any misrepresentation on my part.

I should like, at the same time, to state, with reference to my remark, that the results of the South Foreland experiments "are stated at length in the third edition of Dr. Tyndall's book on 'Sound,'" that the results are given at length in the "Philosophical Transactions" for 1874, and are concisely stated in Dr. Tyndall's book.

E. PRICHARD EDWARDS.

Trinity House, London, 21st December, 1880.

### SEA SIGNALS.

In Cliffe's "Book of North Wales," 1850, p. 118, it is stated "that this coast (Anglesea), is the resort in the breeding season of sea-birds, gulls, &c. No one, by order of Government, is allowed to shoot the birds, as in foggy weather they are invaluable to steamers and shipping, being instantly attracted round a vessel, or induced to fly up screaming by the firing of a gun. Captain Skinner's mail-packet was once saved in this way. The birds deposit their eggs in vast numbers on

the south side of the Stack rock, and are then tame. The gulls assemble here on the same night, on or about the 10th of February, when they make a great noise, and nearly all retire about the 12th of August." The Ailsa Crag, Bass Rock, and Skerries, are notable for sea-birds, now legally protected, and useful for sea signals. Their wholesale destruction is not only wanton, but mischievous.

CHRISTOPHER COOKE.

London.

## OBITUARY.

**Frank Buckland.**—Although he was not a member of the Society of Arts, the death of this well-known zoologist, on Sunday morning, 19th inst., will be deeply regretted by a large number of the members, who have always appreciated his appearance at the meetings of the Society. Francis Trevelyan Buckland was the eldest son of the Very Rev. William Buckland, D.D., Dean of Westminster. He was born on the 17th December, 1826, and was educated at Winchester and at Christ Church, Oxford. Having studied medicine in Paris and London, and served as house-surgeon to St. George's Hospital, he entered the 2nd Life Guards in 1854, as assistant-surgeon. He left the army in 1863, and for a time was a constant contributor to the *Field* newspaper and other periodicals. In 1866, with the late W. Pennell, the first Inspector of English Salmon Fisheries, Mr. Buckland projected and started *Land and Water*. He conducted its intelligence in regard to sea and river fisheries and practical natural history, and contributed to it up to the very day before his death. In 1867, Mr. Buckland was appointed Inspector of English Salmon Fisheries, and his advice was sought by the Governments of Russia, Germany, France, America, &c., as well as by our colonies. In 1868, Mr. Buckland gave evidence before the Food Committee of the Society, and served on the Piscicultural Committee in 1869. In 1870, he was appointed Special Commissioner for the Salmon Fisheries of Scotland. He published a report on the Norfolk fisheries, which led to the Norfolk and Suffolk Fisheries Act of 1877. In the same year he was one of a Commission to inquire into the crab and lobster fisheries of England and Scotland, which resulted in an Act of Parliament for the protection of those molluscs. In 1877, he also served on a Commission of inquiry into the herring fisheries. In the next year he was engaged upon the Commission relative to the sea fisheries around England and Wales, a report upon which was published last year by Mr. Buckland and Mr. Spencer Walpole. The first paper contributed by Mr. Buckland to the Society, which was on "The Acclimatisation of Animals," was read on November 28th, 1860, and the last occasion on which he presided at a meeting was on April 25th, 1879, at the reading of Mr. Willis Bund's paper on "English Fresh Water Fisheries." He was then in feeble health, and was forced to leave the chair on account of illness. His *Juvenile Lectures* on "Birds, Beasts, and Fishes," in 1873, most successfully commenced these annual series of Christmas lectures.

## GENERAL NOTES.

**Royal Institution.**—The lectures for the Friday meetings, before Easter, 1881, are arranged as follows:—January 21st, Warren De La Rue, Esq., D.C.L. F.R.S., Sec. R.I., "The Phenomena of the Electric Discharge, with 14,000 Chloride of Silver Cells." January 28th, Dr. Andrew Wilson, F.R.S.E., "The Origin of Colonial Organisms." February 4th, Dr. Arthur Schuster, F.R.S., "The Distances of the Stars." February 18th, Sir John

Lubbock, Bart., M.P., D.C.L., F.R.S., "F Seeds." February 26th, Dr. J. S. Burdon L.L.D., F.R.S., "Excitability in Plants and March 4th, Sir William Thomson, LL.D., "Elasticity Viewed as Possibly a Mode of Motion 18th, William H. Stone, M.D., "Musical Pitch Determination." March 25th, Alexander Buch F.R.S.E., Sec. Met. Soc. Scot., "The We Health of London." April 8th, Prof. Tyndal F.R.S. The lectures for March 11th and April yet fixed. Prof. Dewar will give the first of his Lectures (adapted to a juvenile audience) on Tuesday next, December 28th, at three o'clock Royal Institution.

**Trans-Australian Railway.**—The colony of land seems likely, according to *The Colonies* and be the first to put into practical execution the long hope of a trans-Australian railway, which shall connect the northern with the southern shores of the island and bring the colonies within 80 days of England those which are now practically most distant from the nearest in point of time, as they are by geographical position. The original route proposed for a trans-Australian railway was from Port Augusta in Australia to Palmerston, the central port of the coast, adopting generally the line passed through existing overland telegraph. The distance to be a direct line from the northern terminus of the South Australian Railway to Palmerston is 1,400 miles, and the connecting links would have to be constructed by direct communication between Port Augusta and Sydney. By the new route now proposed, finally adopted by the Queensland Government, the following advantages are secured. The principal railway from Brisbane has just been completed in a north-westerly direction to Roma, a distance of 317 miles, and from this point to the nearest port of Carpentaria on the north coast is, in a direct line, 860 miles. The line would almost touch on its way the important railway from Rockhampton to Emerald. The blanks to be filled up in the existing lines between Brisbane and Sydney are no greater than the links to complete the chain between Adelaide and Sydney. When the latter are completed, there will be, on the complete new projected line from Roma to the Gulf of Carpentaria, continuous railway communication between the northern and southern coasts of Australia, having the additional advantage of traversing the whole of the most settled district, meeting all the principal cities, except those in the interior of Australia. The Queensland Government has passed an Act authorising the construction of the trans-continent, and a syndicate has already agreed to perform the work on the condition of receiving, among certain other privileges, an area of 8,000 acres of land for each mile of railway constructed.

**French Fruit and Vegetable Trade.**—M. J. some statistics, in a recent number of the *Journal* of the Central Horticultural Society of France, relating to the exportation of fruits and vegetables into France in 1877, 1878, and 1879, as well as to the quantities of the same years. The number of kilogrammes of oranges imported amounted in round numbers to 37,000,000 in 1877, 34,000,000 in 1878, and 37,000,000 in 1879, the largest amount. Of other fruit imports, lemons amounted to 5,000,000 kilogrammes in 1877, 1878, and 15,000,000 in 1879. Italy and Belgium imported the largest proportion, but there is also a considerable exportation of this class of fruit from England, amounting to 362,000 kilogrammes in 1877, to 107,000 in 1878, and 42,000 in 1879. 4,000,000 kilogrammes were exported from Italy into France, or double the amount of the year. As to the exportations from France, the quantities of oranges and similar fruit amounted in 1877 to 4,000,000 kilogrammes, in 1878 to nearly 8,000,000, and in 1879 to 2,500,000 kilogrammes. Of other fruits, the quantities exported from France to England were upwards of 19,000,000 kilogrammes, in 1878 to 24,000,000, but in 1879 only 18,000,000 kilogrammes, the quantities exported from France into Italy were, in 1877, upwards of 103,000,000 quintals, more than 107,000,000 kilogrammes, and in 1879, 103,000,000 quintals.

## OF THE SOCIETY OF ARTS.

No. 1,467. VOL. XXIX.

DAY, DECEMBER 31, 1880.

Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.

## EDINGS OF THE SOCIETY.

## JUVENILE LECTURES.

at of these lectures, on "Animal ce," was delivered by Mr. G. J. F.R.S., on Wednesday evening, 29th the lecturer devoted the whole of his the consideration of the habit of Ants, ured his subject under the following seven I. Sense of sight, hearing, and smell. e of direction. III. Power of communi- IV. Powers of memory. V. Affection nosity. VI. General habits. VII. General noc. Each of these divisions was illustrated notes, related on the authority of trust- observers, such as Huber, Lubbock, Belt, Lapecomb, Moggridge, and others. The lecture will relate to the intelligence of the animals.

## CANTOR LECTURES.

## POINTS OF CONTACT BETWEEN SCIENTIFIC AND ARTISTIC ASPECTS POTTERY AND PORCELAIN.

Prof. A. H. Church, M.A. Oxon., F.C.S.

II.—DELIVERED NOVEMBER 29TH, 1880.

*Enamels, Iridescent and Metallic Lustres, and Colouring Substances.*

the form, texture, and colour of unglazed whether the body be merely drawn together as in the softer terra-cottas, or whether it or less vitrified, as in the "red opaque of Böttcher and Elers, and the black of Wedgwood—from considering the elements of the bodies, we pass natu- be various modes of enriching the surface laces and enamels supply. We shall d this part of our subject more tho-

roughly, if we classify the constituents of all ceramic wares, not of the glazings and slips only, but of the bodies also, somewhat after the following fashion, noting the characteristic property which each separate constituent does, as a rule, confer upon the product to which it has been a contributory:—

i. <i>Refractory.</i>	ii. <i>Hard.</i>	iii. <i>Fusible.</i>
Alumina.	Silica.	Lead oxide, Potash, Soda, Boric acid, Lime, Baryta.
iv. <i>Col.rant.</i>	v. <i>Lustrous.</i>	vi. <i>Opaque.</i>
Iron, Copper, Cobalt, Manganese, Chromium, Antimony, Nickel, Uranium.	Gold, Platinum, Silver, Bismuth.	Barium sulphate, Bone-ash, Binoxide of tin.

But no sharp distinction can be drawn between these six classes, if we include in our view all possible combination of them one with the other; or if, on the other hand, we exclude completely from a ceramic composition one or more of the chief members of the first three classes. Lime, for example, usually aids in the fusibility of a body or glaze, forming with silica a silicate, which melts without difficulty. But nothing—not even alumina—is so refractory as pure lime, from which crucibles for use with the oxy-hydrogen blow-pipe, and for the fusion of platinum, are made. Again, iron is set down as giving colour, but it unites with silica and small quantities of lime or alkaline oxides to form a kind of half-glaze. This Japanese bottle shows three conditions of surface on unglazed brown stoneware: a surface on which an iron ore, containing nearly 90 per cent. of oxide of iron, has been spread; and a region near the mouth, to which some small sprinklings of felspathic clay have been further added. The gloss of the three surfaces has been progressively increased, while the microscopic examination of the glazed portions indicates the cause of the beautiful colours and textures which have been formed. One of the crystalline kiln-products thus formed within the glaze is a copper-coloured complex ferric silicate, which is a very common constituent of ferruginous glazes. Some bricks offer instances of such iron glazes, often produced irregularly and accidentally. The so-called Samian ware, with its sealing-wax red glaze, and the black Greek vases, show what colour effects are producible by fine compositions rich in iron.

In studying the relations of glazes and enamels to the decorative effects which they produce, it will be useful to consider these three qualities:—

- (a.) Transparency, translucency, or opacity.
- (b.) Colour, whether below, in, or above the glaze; its distribution; its quality.
- (c.) Lustre; its quality and position.

Keeping these points in view, it may not be without use if I give you a brief account, arranged in some sort of chemical, historical, and artistic sequence, of the chief glazes and allied preparations, which we must consider if we would properly

understand the decorative results achieved by their use.

**Soda Glazes.**—Although early feldspathic glazes owe their vitrescence to potash or soda, yet the alkaline glazes from “natron,” the native carbonate of soda from Egyptian soda-lakes, from the mixed potash and soda salts of burnt seaweed, and from the potash salts of burnt land-plants, are earlier in date. Babylonian and Assyrian enamelled bricks (circa B.C. 700 — 600) contain, like those of Egyptian origin, silicate of soda as the basis of the glaze, with copper, iron, antimony, and even lead for colouring (the last for increasing the fusibility also). Old Indian enamels, dating at least from the thirteenth century of our era, contain a silicate of soda and copper, yielding a fine turquoise colour; and also another soda silicate, tinted by oxide of cobalt. Soda glazes, when not too alkaline, possess the merit of being unaffected by the water, the carbonic acid, and the sulphuretted hydrogen, which, singly or conjointly, tend to disintegrate, or at least to roughen and tarnish, many glazes containing lead. And it is by the aid of soda alone that certain hues, as that of the turquoise, can be developed.

**Potash Glazes** are mainly those which are formed from felspar and from china-stone, which contains both felspar and immature kaolin, from which by no means all the alkali has been eliminated. Of these glazes I shall have something to say further on in the course, when speaking of hard porcelains. But potash glazes, properly so-called, can hardly have originated otherwise than by burning land-plants with or on sand, by which glaze, the typical glaze, was first produced.

**Lead Glazes** can, in England, be traced back to the first or second century. Several Roman lamps show a green glaze, containing much lead, coloured by iron and copper; one found at Dorchester, Oxon, is in my collection. All the early mediæval tiles in which England excelled are glazed with lead. Litharge ( $\text{PbO}$ ), red-lead ( $\text{Pb}_2\text{O}_3$ ), white-lead ( $2\text{PbCO}_3$ ,  $\text{PbH}_2\text{O}_2$ ), and lead glass were all, and are all, employed; to these materials must be added galena, the native sulphide of lead. A previous “fritting” of the plumbiferous substance is advantageous; first, in order to secure the combination of the lead oxide with the china-stone, flint, or other silicious materials of the glazing mixture; second, to allow of the lead being lowered to a minimum amount; third, to increase the hardness and insolubility of the glaze. Lead certainly develops (as does zinc oxide also) the beauty of some of the enamel colours, and it would be hard to exclude it from all glazes, although borax and boracic acid, the chemical function of which is different, may replace it to some extent, and in many instances. Two marked peculiarities belong to lead glazes—one of these is the yellow tint (fused lead protoxide and highly plumbiferous silicates are yellow), which glazes containing much lead give to white clays, an effect seen on many early tiles and other specimens of early English pottery; and the other peculiarity of lead glazes is the iridescence, often beautiful, caused on their surface by their commencing decay.

**Tin Glazes**, often called enamels *par excellence*, owe their gloss, generally at least, to lead, the tin binoxide merely imparting whiteness and opacity. Babylonian and Assyrian specimens are known,

but the use of tin seems to have been long times, and the lack of acquaintance with perties, or perhaps rather of the opportunity of securing a supply, seems to have caused a delay in its employment. The tiles of Mahom (A.D. 707) contain neither lead nor tin. Biferous glazes were introduced into Spain by the Moors in the thirteenth century; they were introduced into Italy as early as 1400. There is great hardness and coldness when tin glazes are applied upon; a subsequent transparent glaze is used to obviate this defect; but they are not adapted for highly pictorial and precise work. A tin glaze lies in the ease with which these tin glazes are detached from the porous bodies to which they are usually applied. This tin enamel often contains too much tin oxide—sometimes twice as much as the newer than in the older specimens. The consequence of the difference is seen in the colours lie on the surface when it is rubbed, but in the opposite case they work into the surface during firing, and so produce a softer effect. Works in basso and alto relievo one would say that tin glazes were ill-adapted, but in the works executed in this manner by Luca della Robbia, the Florentine sculptor, Florence one forgives the glitter and the loss of these works, the rounded obliteration of the finest thought and expression of the artist. Yet his terra-cottas, when not covered by a “majolica cream,” if more injured, are not less lously finer.

**Smears** are closely allied to glazes, and have the same chemical composition and in decorative effect but their appearance, if less even, is more quiet and delicate. It is often noticed, that they acquire a partial or slight gloss, the volatilisation of alkalis or lead from the surface coated with glaze, and fired in the same manner, sometimes the same effect is produced without firing, throw up to their surface their more finely comminuted, or more fusible constituents. “Smearing” is now employed to a considerable extent, as affording a useful application through the kind of half-glaze which produces. Red lead, china-stone, sal bone-ash, nitre, litharge, and flint, added singly or more of them together, or, in some cases, are the chief constituents of the wash and are applied as a kind of wash on the surface of the saggars in which the pieces are fired. “Flows” resemble smears; additional used in them are lime, alum, whiting and ammoniac.

Passing from glazes to colouring, we find that the preparations employed in decoration may be classified rather in the manner of application than by their chemical composition, although this has to be taken into account according to the material to be painted and the temperature of the firing. Some colours are on the body, encaustic; some are on the surface, under the glaze; some are in the glaze, and some are over the glaze. This list by no means exhausts the series, for we have colours placed on the surface and others on enamel. A very large number of colour effects are producible by the position of the colouring substances, while nearly as many may be said of the results attainable by the quantity and nature of the associated c

of the ceramic pigments, whether these constituents be fusible or refractory.

*Encaustic* colours were used by Wedgwood, in his classical paintings upon basaltes and coloured clay bodies: they consist of slips of opaque clay, to which various colour oxides, such as those of cobalt, chromium, and iron, are added. They are employed in *pâte sur pâte* decoration, and very extensively in paving tiles and mosaic tesserae. They are applicable to opaque bodies, and to those that are translucent; to those fired at low as well as at high temperatures.

*Enamel* colours illustrate another way of employing the colouring power of certain metallic oxides; in these there is a glass of silicate of cobalt, silicate of iron, &c., or of borate. China clay is mixed with some, and with some felspar; some are nearly pure silicates. Pure oxides, as that of cobalt, do not belong here, and such preparations are mainly used for underglaze painting, on such bodies as need a high temperature for firing.

Some interesting contact points between chemistry and art come out, on the consideration of the several metals to which the colours of pottery and porcelain are due.

*Iron* yields a fine red when fully oxidised, and then neither alkali, nor lime, nor barytes, nor magnesia, nor a very high temperature, impair its beauty. Much of the Kaga ware of Japan, and the underglaze red of certain Chinese porcelains, illustrate this point. Then the silicate and borate of protoxide of iron are green; the mixed oxides brown, or even black. But much depends upon the form in which the iron is introduced, much upon the temperature, and much upon the fuel. The effects of alkaline bases on iron hues have been pointed out in the previous lecture; an instructive example is furnished, as I pointed out many years ago, by the red chalk of Hunstanton, in Norfolk. When strongly ignited, this becomes an olive green, owing to the formation of the compound— $\text{Fe}_2\text{O}_3, \text{O}$ .

*Cobalt*, from which the majority of our blues are derived, is difficult to manage, both in hue, depth, and brushwork or application. The bold pulsating use of choice specimens of old Chinese blue and its use is perfect, so is much of that found in Persian, Damascus, or Rhodian faience. When cobalt contains nickel, or manganese, or iron, or usual impurities, it is greatly injured; at last, its hue becomes so modified towards grey, green, or purple, as to lose its distinguishing identity.

*Copper*, though of a rich green in the form of malachite, becomes, by reduction to suboxide, capable of yielding a characteristic red. Pleasing effects are produced by blowing a reducing atmosphere, in spray, upon the turquoise green enamel of certain cupreous preparations. *Manganese* may yield a puce, a violet, or a plum colour. It probably does not exist in ceramic materials, either as  $\text{MnO}_2$ , or salts of  $\text{MnO}$ . Its effect is frequently dulled by ferruginous impurities, sometimes by barytes or copper. With chromium and cobalt it yields a black.

*Arsenicum* is known to exist in two conditions of oxidation; one bluish-green, the other yellow; in bases are abundant, it more readily tends towards the latter state. But chromium yields, in presence of tin (of stannic oxide), a beautiful

rose colour, which is generally known as "pink colour," and has been largely used in ceramic decoration. The peculiarity of the composition of this colour lies in the very small proportion of chromium which it contains.

Almost every metal belonging to what is called the "heavy" class, may be used for colouring—the alkaline metals, the earthy, and the alkaline-earth, are destitute of this power.

After colours come lustres. They do not necessarily depend upon the actual metallic condition of certain constituents on the surface. Nor do metals, even if free, that is, in their proper metallic condition, invariably present a lustrous appearance. The metal employed for lustring is bismuth, patented by Brianchon, and imitated at Worcester and Belleek; it gives a beautiful iridescence, which has been too lavishly used—smeared over everything—or it would be more appreciated. Copper and silver give lustre to Italian wares, decorated at Gubbio, Pesaro, and Deruta, and also to some wares produced in Persia and in Spain. In the last half of the eighteenth century, at Brislington, near Bristol, and in Staffordshire, by Wedgwood, lustres fair in tone, but unsuccessful in decorative treatment and association with other colours, were made. Gold was used by Wedgwood, not only for ordinary gilding on his wares, but also for staining them and lustring their surface. Platinum was employed by several potters of the eighteenth century, in Staffordshire. Messrs. Lockett and Co., of Longton, in 1862, manufactured many lustrated pieces. Carrocci, of Gubbio, now prepares a beautiful ruby lustre; and for some years past, Mr. William de Morgan, of Great Cheyne-row, Chelsea, has produced both ruby and mother-of-pearl lustres of great beauty. The designs on his pieces are so fresh and so good that one cannot but rejoice in this combination of remarkable excellence in drawing and chromatic effect. More recently, Mr. George Maw, of Benthall-hall, Broseley, has turned his attention to the production of lustres. His ruby lustre frequently (in fact, nearly always) possesses that quality of transparence which marked the Gubbio ruby, and which modern lustres nearly always miss.

In drawing your attention to the specimens on the table, some of which are old, and many new, some European and some of Eastern origin, it may be useful if I point out, not only the lessons which individual examples may teach, but a general difference of character or feeling between modern work, and much European work generally, on the one hand, and old and most Eastern work on the other. As such general difference lies almost wholly in the glaze and its associated chromatic elements, this place seems to be the most appropriate for its consideration. Modern work is prosaic, laboured, uninteresting. If it be learned, it is not learned enough. If its decoration were the outcome of nothing more than unspoilt tradition, the decorative result would be more satisfactory. But the obvious striving after effects and qualities which are yet imperfectly realised, pains the artistic sense of those persons who are familiar with the productions of other times and other countries. If one examines a modern piece of English turquoise glaze, a very noticeable defect obtrudes itself on the eye at once. The colour is staring enough,

strong enough (what the French call *voyant* and *criant*), but muddy withal; you cannot look into it. If a mottled, or flooded, or varied glaze be attempted, the result realises the mottling or other peculiarity of the Chinese original distinctly, but misses its easy, careless grace, whereby art conceals artifice. Of course all modern and all English work is not amenable to such criticism. For instance, Mr. W. De Morgan's Persian tiles are worthy of unqualified praise. On the red body beneath, a white slip or wash is placed, which, while illuminating the nearly transparent turquoise, puce, and blue glazes above, does not reveal itself, nor disclose the mechanism of the final success. Here, too, the design of the ornament, the quality of the hues, the degree of gloss, and the blending of contiguous colours are all just simply perfect. And it is not difficult to discover similar meritorious elements in the productions of other factories. Here is a specimen of modern Hungarian earthenware, in which, upon a softly mottled ground of dove-colour and crimson, a graceful network of golden foliage is spread. And these beautiful tile-pictures, by Messrs. Simpson, of St. Martin's-lane, illustrating both underglaze and overglaze painting, show the association of high artistic power with the frank recognition of the nature of the materials, and the uses to which the objects are to be put.

A few words must now be said about the specimens of glazes and colours, which are on the table. Ferruginous glazes are shown in these Japanese bottles, and in this tye of the 15th century, from the ruins of the Blackfriars monastery in Bristol. This English mediæval jug shows a green glaze, due to a silicate of lead, copper, and iron. This large mottled Chinese dish, and this octagonal old Staffordshire tortoise-shell plate, owe their colours to manganese, copper, antimony, and iron, the glaze in both cases being rich in lead. A milk jug, of about 1750, shows how a lead glaze brings out the colours of the two clays, one white, the other buff, from which the vessel has been fashioned. This old Staffordshire agate-ware sauce boat exhibits the softening, because solvent, effect of a lead glaze upon the irregular patches and strings of parti-coloured clays, tintured with cobalt and iron, of which it has been formed. A Japanese plate, by Kenzan, of about 1730, exhibits the effects of a vitreous glaze upon a rough clay, and also affords a good example of glaze upon a white slip. Another bit of Japanese ware, quite modern, is of buff clay on white; the simple decoration is in delicately pencilled white clay, the glaze just developing the colour of both body and design, and not obtruding itself by excessive gloss. Here is a bowl of old Kaga ware, where the brown body tones down the brilliancy of all the enamel colours, save the opaque blue, with which it is decorated. Here, again, is a tea bowl, where the one point noticeable is a rich brown glaze, free from lead, but of absolutely perfect gloss. Looking into this glaze, we see its tones are beautifully varied from base to lip, and that there is no monotony, as of textureless varnish, anywhere in its substance. A white, porous clay bowl, with cinque-foils in manganese, purple and dim undulatory lines of cobalt blue, both underglaze, shows the penetration of these colours into the body, and how the glaze has

softened and united the whole into one. Often, in these Japanese wares, we may play of colour and texture obtained simple means as glazing with a colour one part of a vessel, leaving another part coating another part with a white enamel, and tincturing a fourth part with son colour. This treatment has been adopted on this vessel, shaped as a leaf, and lends a peculiar appropriateness to the convenient presentation of the texture, substance, veins, undulations, and margins. Of other Japanese wares, here are half a dozen characteristic examples, each capable of teaching a lesson to Western potters.

These examples of Persian and Rhodian and their imitations are most instructive show, above all things, how useless it is the imitation of an effect by means of artificial materials having wholly different physical chemical characters. Does this modern Persian *faience* realise any of the beauty of the original? Is it not a ridiculous caricature at the carefully painted imitation of the spreading at the edges of the colours, the opaque, uninteresting body. Here it downwards into the clay, and no discolouration in the glaze.

The stanniferous enamels of Italy are their best in such examples as this di Caffagiuolo; at their worst in this plate of origin of about 1710. Bristol, Liverpool, Dutch tiles of the eighteenth century teach us useful lessons, especially when compared with these works of Decks (both of Paris), in which the stanniferous and the enamel painting which it carries at the same time.

## MISCELLANEOUS.

### REPORT ON TWO EXPEDITIONS TO

By Captain R. F. Barton.

The following lines contain a concise account of circumstances which, during the last three years, connected me with the Egyptian province.

H. H. Ismail I., honoured me, through Frederick Smart, with an invitation to visit to lay before him certain details which I had concerning mineral wealth in N. Western A. I left Trieste on March 3rd, 1877. A steamer was at once prepared: it set out for El on April 2nd; and returned to Suez on April 18th. During those 18 days we found, by examination, that the country had been extensively explored, while a larger area remained untouched.

Some specimens of gold, silver, galena, zinc, sulphur, iron, and other metals. H. H. Ismail I. pleased, and promised me, in presence of Mr. de Sautour, either a concession or a 5 per cent. on gross produce.

Returning from the first expedition I had to recommend—1. Mr. Charles Clarke (for the rank of Bey. 2. Lt. Hasan Effendi Lt. Amir Effendi Hushdi for a step in pay also solicited a small life-pension for Haji W.

of Zagazig, who had drawn my attention to the mines of El-Madyan.

On October 9th, 1877, I again left Trieste. After some delay at Cairo, the second expedition set out from Suez on December 11th; and returned on April 12th, 1879. During this journey of four months, Mr. Marie, the engineer sent out by H. H., collected some 20 tons of specimens, and I was directed to have them assayed in London, while Mr. Smart was charged, in my presence, with furnishing the necessary funds. The analysis was duly made and the printed report was forwarded to Egypt; but funds were not forthcoming, and the consequence was, that I was compelled to supply them.

Returning to Cairo I renewed my request touching the person of Haji Wali; I again submitted for promotion the names of Mr. Clarke and Lt. Amir Effendi Rashid, and I added to them that of Ahmed Kapitan Khalil. Moreover, for the better government of the province (El-Madyan), which is about to assume new relations with Egypt, I had the honour to propose—1. That Sayid Abd el Kahim, accountant of the Fort El-Maryut, be raised to the rank of Nazir, or commandant. 2. That Mohammed Shahadeh, Ex-Wakil of El-Wijh be made commandant of that fort. 3. That some title of H. H.'s favour be conferred upon Sheykh Alyan Ben Rabi of the Huwatat tribe, Sheykh Furayj of the Hawati tribe, Sheykh Hassan Ibn Salim El-Ghali.

For the safety of Egypt and Europe I also recommended that the quarantine establishment be re-transferred from Tor harbour to El-Wijh.

Since leaving Cairo (May, 1878), I have repeatedly written concerning the administrative measures to be adopted before the country can be regularly exploited, but hitherto my representations have remained unnoticed.

I now return to the mines. The result of the assays made by three several establishments is so far encouraging that Dr. Percy, one of the highest authorities on metallurgy, declares "These indications of the presence of the precious metals certainly justify further explorations." Such exploration I am prepared to undertake.

I left Trieste on December 5th, 1879, and came to Cairo ready for a third expedition. This time the conditions of exploration are more favourable, as I have no longer to seek for the sites which are best fitted for beginning operations.

It is, however, evident that no syndicate, no company, would risk capital upon a project, however promising, without the prospect of enjoying the fruits of success. Certain capitalists in London are willing to aid me, but it will be upon conditions that a formal concession or concession be granted to me.

The *Decree Règlement sur les mines de l'Empire Ottoman*, inserted in the *Transimat* (Constitution) and bearing date July 17th, 1861, authorises this concession, and lays down all the legal conditions regarding royalty and other matters.

An objection might be raised that the *Règlement* applies to subjects of the Porte. But, firstly, there are precedents for extending the privilege to foreigners; for instance, in the case of the minerals about Bidon. Secondly, this proviso, made for Turkey proper, is not applicable to Egypt, where there are now international minerals. Disputed questions of royalty, jurisdiction, &c., could be settled by arbitrators, the latter nominated in equal numbers by the Government and the company.

The public will observe that I am not acting as one who seeks to receive favours from Egypt. On the contrary, I propose to develop a province which has been for centuries, and which still is, a howling wilderness, occupied by a few hundred Bedawin. I propose to benefit Suez and the adjacent parts of Egypt by creating an industry and a traffic where there is now nothing of the kind. Lastly, I propose adding to the resources of

H. H.'s Government, by making over to it the legal share of whatsoever profits may accrue from the exploitation of El-Madyan.

Under those circumstances I have a claim to expect the realisation of a project whose views are of the most legitimate. And the first steps would be—1st. A contract or concession drawn up in due form. 2nd. An authority to carry out the measures proposed for the government of the province; especially the rewards due to the military officers and the civilians who assisted in exploring El-Madyan.

## THE NATIVE SILKS OF ASSAM.

By C. G. Wernford Leach.

The native silks of Assam, known as *Bris* and *Muga*, are the produce respectively of *Attacus Bicornis*, and *Antheras assama*, and *Antheras Mousabouria*.

The *Bris* worm is so called from the local name of the castor-oil plant (*Ricinus communis*), on which it is almost exclusively fed. It is reared entirely indoors. The duration of its life varies with the season: in the summer, it is shorter, and the product is both better and more abundant. At this season, 20 to 24 days elapse from the date of its birth to the time when it begins its cocoon, 15 days later the moth is produced, in three days the eggs are laid, and in five more they are hatched, making the total duration of a breed 43 days. In winter, its life extends to nearly two months. Seven breeds are reckoned upon annually. For breeding, the natives select cocoons from among those which begin to be formed in the largest number on the same day. Those containing males are recognised by a more pointed end. On the second or third day after the cocoons have begun to be formed, they are put into a closed basket, and hung up in the house, out of reach of vermin and insects. Twenty-four hours after the moths have been produced, the females are tied to long reeds or canes, 20 to 25 to each, and these are suspended in the house. The eggs laid during the first three days alone are kept; they are tied up in a piece of cloth, and hung from the roof till a few begin to hatch; these eggs are white, and resemble turnip seed in size. When a few of the worms are hatched, the cloths are put on small bamboo platters, and here they are fed with tender leaves. After the second moulting, the worms are removed to feed on bunches of leaves, suspended a little above the ground, and a mat is spread beneath to catch those which fall. When they have ceased feeding, they are placed in baskets filled with dry leaves, amongst which they form their cocoons. In four days, the latter are complete. A selection having been made for the next breed, the remainder are exposed to the sun for two to three days, to destroy the vitality of the chrysalis. The cocoons are next generally put into water containing potash (wood-ashes), over a slow fire; when removed, the water is gently squeezed out. At other times, they are massed together for some days with *amaruta* (*Y. Carica papaya*) or *madhu* fruit. The object is the same in either case, viz., to facilitate the drawing of the silk. The cocoons thus treated are taken one by one, and the silk is placed within the thumb of the left hand, whilst the right is employed in drawing out the silk. Any inequalities that may exist are reduced by rubbing them down between the thumb and finger, the same process serves for joining on new cocoons. The thread is allowed to accumulate in quantities of about half-a-pound, these are afterwards exposed to the sun, or placed near a fire, till dry, when they are wound up into skeins. The silk is then ready for the weaver. It is the coarser of the two kinds, and none of it ever finds its way into Bengal.

The *Muga* moth is found wild in the jungle, but all the silk produced by it is from domesticated worms. They are reared on trees in the open air. These are

generally five breeds in a year, viz., January to February, May to June, July to August, September to October, and November. The first and last yield the best crops, as regards both quantity and quality. Constant watching of the tree is necessary. By day, crows and other birds pounce upon the worms, and devour them. By night, bats, owls, and rats are very destructive. Numbers of the caterpillars are destroyed in the more advanced stages by the sting of wasps, and by the ichneumon insect, which deposits its eggs in the bodies of the worms. The latter thrive best in dry weather, but a very hot sunny day at the moulting time proves fatal to many. Indeed, at this period, rain is considered very favourable; and even thunderstorms are not injurious, as they are to the mulberry worm. Continual heavy rains do mischief by sweeping the worms off the trees; but showers, however violent, cause no great damage, the worms generally taking shelter under the leaves with perfect safety. During moulting, the worms remain on the branches, but when about beginning to spin, they come down the trunk. Bunches of fresh plainain leaves are tied round the trunks at some height from the ground, in order to arrest their progress. The worms are then collected in baskets, which are put under bunches of dry leaves, suspended from the roof of the house; they crawl up into these, and there form their cocoons. The total duration of a breed varies from 60 to 70 days; the period is thus divided:—4 moultings, 20 days; from fourth moulting to beginning of cocoon, 10 days; in the cocoon, 20 days; as a moth, 6 days; hatching of the eggs, 10 days; total, 66 days. The chrysalis not being easily killed by exposure to the sun, a number of cocoons are placed upon bamboo stages, and covered with leaves, whilst a quantity of dry grass is ignited below them, and in a short time destroys them. The cocoons are then boiled for about an hour in water containing potash (the ashes of mustard and other plants). When taken out, they are laid between folds of cloth. The floss is removed by hand, and the cocoons are thrown into hot water. The instrument used for winding off the silk is the roughest imaginable. A thick bamboo, about 3 ft. long, is split in two, and the pieces are driven equally into the ground about 2 ft. apart; over the interior projection of one of the knots is laid a stick, to which is fixed, a little on one side, a round piece of plank, about 1 ft. in diameter. The rotary motion is given by jerking this axle, on which the thread rolls itself. In front of the vessel holding the cocoons, a stick is placed horizontally for the thread to travel upon. Two persons are employed—one attends to the cocoons; the other jerks the axle with the right hand, and with the same hand directs the thread up the left forearm, so that it is twisted in coming down again towards the hand, while the left hand conducts the thread over the axle. The Assamese consider it a good annual return if an acre of trees support 50,000 cocoons, yielding upwards of 24 lb. of silk. It must be very profitable, as 1,000 cocoons are reckoned to afford 6 to 8½ oz. of silk thread, selling at 10s. to 12s. a pound. The labour and expense of maintaining a plantation of the trees is very trifling.

Two kinds of silk are distinguished by the natives as the production of the *Muga* worm—*muga* and *mujankuri*, their difference being attributed to the trees on which the worms are fed; but naturalists have determined a specific difference in the worms themselves, calling the former *Antheraea assama*, and the latter *Antheraea Mezan-kooria*. The *Muga* worms feed chiefly on the *Sum* tree (? *Artocarpus chaplasha*; *Tetranthera lanciolata*); *mujankuri*, from those fed on the *Adakur* tree (? *Tetranthera quadrifolia*). The latter is whiter and better than the former. Some of the silk thread produced in Sibsagar sells for as much as 36s. a pound. Lakhimpur, in 1871, exported 11½ tons of *Muga* silk thread, valued at £6,090.

The reader may refer to the *Journal*, May 9th, 1879, for further information on Indian wild silks.

## CULTIVATION OF THE FIG IN

The United States Consul at Smyrna states that the Aidin district is the only one which produces figs for exportation. The fruit will grow anywhere in the neighbourhood of Smyrna, of a good quality, in a green state; but the Aidin is unique in its climate and soil as being favourable for the proper curing of the fig. The thermometer falls below three or four degrees under Fahrenheit in the summer seldom rises above 70° Fahrenheit in the sun. In Aidin, the weather is generally wet, the dry weather commencing in the middle of October. Any rain in the month of July, or during the month of August, when the fruit is under the process of drying, gives the fig a dark colour, and spoils its quality. Heavy dews will cause the same.

The fig tree will grow in almost any soil; soil is, however, preferable; but to produce a dry well and please the merchant, the soil should be of a good depth, and of a rich, light, sandy soil if the weather be favourable, will produce a white thin skin, and of the finest quality. The ground is well ploughed to a good depth, well fertilised, and all weeds and extraneous roots. The figs are selected with as many fruiting slips. To form a tree, two slips are planted apart, and then joined at the top. They are planted in rich soil, should be placed 25 feet apart, and for poor soil about 25 feet each other. The cuttings are planted in March, two in each hole, at about 9 inches apart at the root end, and during the growth of the trees, the ground is ploughed up two or three times during the winter or spring, and the same is used to cultivate cotton, sesame, &c.

The fig harvest generally lasts about six weeks. When the fig is ripe, it falls of its own accord. Women and children are employed to pick the fruit into small baskets, to be conveyed to the garden well exposed to the sun, where they are laid on a bed of dry grass, or matting, singly on the top of the other, and are turned over in order to get every part of the fig exposed to the sun. After a few days of this exposure, which are sufficiently dry are selected and divided into first, second, and third qualities, being taken not to dry them too much. They are then sent to Smyrna, where they are assorted for shipment.

On arrival at Smyrna, they are conveyed to the bazaar, or market place, where the merchant early next morning to effect purchases. The fruit belonging to each individual owner are examined, each purchaser giving his own price. A seller is but seldom the owner, the latter being generally represented by a Jewish merchant, at an exorbitant charge of 7 per cent commission. The figs are then, after being conveyed to the packing establishment, to undergo the process of putting into boxes; the sack is laid out on the floor in a square heap, and on the top of the heap are women and girls, emptying the twisting round each fig two or three times with the forefinger and thumb, to render it soft, as required oblong form. On the heap are baskets, into which are thrown separately the first, second, and third qualities to be used for packing; the rest of the whole mass is worthless for putting into boxes, and during the first process, the inferior quality is up and thrown in a separate heap. Under

the Kew Museum, there seems but little doubt that this interesting and peculiar remedy was produced by an Acanthaceae plant, known to botanists as *Rhinacanthus communis*. Whether the material now in Mr. Christy's hands will prove the accuracy of this preliminary determination remains to be seen, as also the question of the actual efficacy of the drug itself.

The vine was introduced into Chili by the Spaniards, soon after their conquest of the country, but although its culture quickly extended over the central and southern provinces, it is only within the last twenty years that viticulture has been systematically carried on. The following particulars by Mr. E. Seve, of Valparaiso, are taken from the *Journal of Applied Science*:—

The region suited for the vine in Chili extends from the north down to Biobio in the south. But in the south, the humidity of the climate will not allow the grapes to ripen without artificial means.

The choice of vines, and their suitability to soil and climate, so as to make a certain class of wine, is a question badly understood in Chili, and to which the attention of the vine growers should be directed, as upon the solution of this point depends in a great degree the future of the Chilean wine production.

The French vines, having more attention paid to them in culture, the soil is kept porous and in good condition, and the roots are cared for during the progress of vegetation. Thus, in the same climate, under the same conditions of soil, in the same vineyard, the French vines will ripen their fruit fifteen days to three weeks before those of the vines of the country, and give a much more abundant produce. The indigenous vines, treated after the French method, improve greatly. This fact is a striking example of the influence of culture on agricultural plants.

pharmaceutical products of China and Japan a interesting field for experiment into their actions and probable values. From time to time, reports from various parts of the world are brought before notice, and of late years many have been to be of great practical usefulness, and are noted amongst our important medicines. Though the number and variety of the substances used in medicine by the Chinese and Japanese are very great, and there are very complete collections of the drugs of these countries have been exhibited at the various exhibitions, especially at the last Paris Exhibition, little has been said towards introducing them in quantity for trial by medical men in this country. Something, indeed, has been done a short time since in this direction by Mr. J. B. Christy, who introduced a number of raw materials and products used as drugs in Japan; these were described and in a series of notes published in the *Therapeutic Journal* at the time. Mr. Christy has recently received a consignment of a drug which is reputed to be very valuable in China, for the cure of certain skin diseases; it is known under the name of Tung-pang-chong, and is said to be produced in the mountains of Siam, whence it finds its way to Hong Kong. In the Kew report for 1877, where the substance is first referred to, it is stated that the chemists in Hong Kong say that they can procure an almost unlimited supply, and even hint at getting and growing it here. From information gathered from the Kew report was written, and from comparison with a very small sample sent to this country with the Kew report, which appeared to be identical, contained in

Up to the present time no serious malady has attacked the vines in Chili. The oidium has been long known there, but the climatic conditions are unfavourable to the propagation of this parasite. After some days of rain in the close of November a little damage has been done. In the Argentine Republic, about Mendoza, where the vine is largely grown, there have been serious complaints for some years of damage done to the vines. But it may be remarked that on the sides of the Cordilleras facing Santiago the rains occur in summer, while in the central regions of Chili they occur in winter. The phylloxera, fortunately, is not known in Chili, and the Government have forbidden the introduction of French cuttings, with the view of preventing the devastation.

The duration of the vine in Chili is considerable; vineyards of fifty years old are by no means rare. The principal kinds of wine made in Chili are as follows:—Those known as Burgundy and Bordeaux in the country are the produce of French vines, and the manufacture is carried on on the same principle. White wine is but little drunk in Chili, hence nearly all the wine made from the French grapes is red. The quality of the white wine is, however, superior to that of the red.

French vines, under good conditions, well cultivated, will yield 100 to 120 hectolitres of wine to the hectare; it is sold in the first year at 40 to 50 centimes the litre, which constitutes a considerable profit. The wine made from the French vines in Chili is consumed in the country and exported to the Pacific coasts.

*Chacoli* is a light wine made with the grapes of the country, and which is only slightly fermented in the vat. It is either white or red. This wine is principally drunk by the working classes.

The ordinary wine of Chili is a species of liqueur wine, resembling Malaga. It is made by adding to the ordinary "must" one-fourth or one-fifth part of boiled wine.

*Mosto* is made more or less like Burgundy and Bordeaux wines, and the manufacture is confined chiefly to the South. The province of Concepcion enjoys a high reputation for it.

*Mosto asoleado* is made from grapes dried in the sun for fifteen or twenty days. The native processes of wine making are of the most primitive kind. The general introduction of good instruments and improved apparatus would render great service to Chili.

*Chicha* is a very common beverage among the poor. It is made much in the manner of white wine, except that the juice which issues from the wine-press is boiled.

In the province of Aconcagua, a good deal of spirit is distilled from wine. It is, however, of bad quality, owing to the faulty method employed. To cover the bad taste of the alcohol obtained by the direct distillation of the marc, it is the practice to add fennel seed. The spirit thus obtained is known as *anisado*.

### LEATHER TRADE.

Particular attention is directed to the present condition of the hide and leather trades in an article in the *Statist*, where the increased competition which the English tanner encounters, is pointed out.

"Taking first hides used in the manufacture of heavy leather, what strikes us is the activity amongst French and German houses for direct shipments. Formerly, England was the great centre for such goods, but now the Continent absorbs by far the largest portion of the trade, especially of South American produce. It is true that a proportion of these hides eventually find their way back to this country, and the strange part is that they are ever allowed to be landed elsewhere, at least to so large an extent. The fact is, after the Franco-German war, a new set of Anglo-German merchants came into existence, with correspondents all

over the Continent, and in this way the import houses are ruled by their foreign coadjutors.

"The rapid increase in the importation of foreign leather into this country during the past ten years supplies material for considerations deeply interesting in a public sense, and of vital importance to the British tanner. As our colonies and dependencies grow flourishing, and feel their strength, so they pour in upon us every product suited to their particular climates, overwhelming profusion. Our tanners now behold the similes of their manufactures sent from every quarter of the globe, yet cannot themselves export without countering serious, ruinous, hostile tariffs."

From a table of the imports and exports of eleven years, from 1870 to 1880 (first ten months), it appears that, in 1870, the imports of leather amounted 11,556,345 lbs., value £759,342, and the exports unwrought leather amounted to 103,788 cwts., value £850,495; of wrought boots and shoes, to 372,601 dozen pairs, value £1,148,423; while, in 1879, the imports had risen to 35,175,036 lbs., value £2,204,386, the exports the same year only stood at 219,829 lbs.; of unwrought leather, value £1,505,312; and 432,312 dozen pairs boots and shoes, value £1,319,598. Thus the imports of leather more than doubled between 1870 and 1879, quadrupled in 1875, and almost quintupled in 1880, and seem likely to stand at the end of the present year 400 per cent. higher than at the commencement of the present decade. The exports of leather have materially increased, but not in proportion to the imports; while the foreign trade in boots and shoes, though above 1870 nevertheless seems stationary, and would be considerably less but for the "British possessions in South Africa."

### SPONGE TRADE IN THE BAHAMAS.

The Report of the Governor of the Bahamas to the Secretary of State for the Colonies has been published as a Blue-book, with the Report of Professor Robinson Lankester, on the artificial propagation of sponge appended. Governor Robinson states that "various causes combined to make the past year a most favourable one to those engaged in the sponge trade. A larger number of buyers than usual appeared in the market, and there was no period when it could be said that prices had a downward tendency. The very high prices offered at the beginning of the year were fully sustained to its end. This strong competition served to stimulate those actually employed in the fisheries to greater exertion, and induced a great many others to enter the business. Absence of heavy gales, and mild weather that generally prevailed, contributed in great measure to favour the efforts of fishermen to meet this increased demand. The successful results of last year's fishery are also somewhat owing to the fact that the sponge beds had whilst the privilege of fishing on the coast of Cuba was accorded to the Bahamian spongers. Licenses to fish on this coast were again issued in 1879 to several vessels, but shortly after their arrival at the sponging grounds they were boarded by Spanish gun-boats and ordered to leave; some of them returned to port with insufficient sponge to pay the cost of their outfits."

Professor Lankester's report was made in accordance with the request of the Secretary of State for the Colonies, and contains the result of inquiries respecting the experiments initiated by Professor Oscar Schmidt, on the artificial cultivation of sponges for commercial purposes.

Mr. Lankester writes:—"The experiments in the Adriatic were carried out under the auspices of the Government during the years 1863-72, and were finally abandoned in November, 1872, on account of the difficulties which were encountered. It appears that the method of cutting a sponge into small pieces, affixing

ances to movable supports, and sinking the sponges in the water where the sponges naturally were found to be perfectly successful. The ends of sponge attached themselves to the supports, and proceeded to grow each into a well-shaped like that from which the cutting was taken. These are given in Dr. Von Marenzeller's report as the best mode of taking the cuttings, and as to the material for supports, also as to the time of year to operate, and other important conditions. It is that from a small cutting (26 cubic millimetres in sponge of marketable size would be produced in seven years' growth. Whilst the experiments of the Austrian Government demonstrated the soundness of Oscar Schmidt's suggestion, in consequence of the cultivation was attempted, yet two difficulties afforded to put a stop to the undertaking. Firstly, the population, more especially the fishermen, raised objection to these experiments, fearing that they might lead to the injury of the sponge trade, and consequently they persistently disturbed and the experimental sponge bed. It was necessary the sponge cuttings on their supports should be in an open unprotected bay, in order to secure the condition of the sea water, and natural food of sponges, and at the same time the expense of protecting the bay during a long series of years against incursions of the fishermen would have been great, and incommensurate with the profit to be derived by the sale of the sponges when full grown. Idleness of the population of the Adriatic coast was the chief cause of the abandonment of the sponges. But, further, the slow growth of the sponges (first established as a fact by these experiments), the expense of obtaining the cuttings, and of sinking the supports, seemed to show with reasonable clearness that the profit to be obtained by a system of cultivation would be extremely

small, if any be possible, by means of the system of sponge cutting; proposed by Professor Oscar Schmidt, to introduce sponges into new situations previously unoccupied, and experiments in this direction, though requiring skill and knowledge of the conditions favourable to sponge growth, would be worth trying. Excepting this object, the method of sponge cutting does not seem to be one of any promise.

In relation merely to the management of an existing fishery, I am of opinion that all that can be done by official control is to prevent the contamination of the natural disturbances of the waters and bottom where sponges grow, and, secondly, to strictly enforce a ban of size in regard to those sponges which are sold. Only large sponge should be moved from the bottom for the market, and all smaller and slightly grown specimens should be returned to the spongers by the fishermen immediately when taken. As the ground on which the sponges grow should not be too often dredged, but only at certain intervals of years. In making these recommendations, I am guided by the opinion of Professor Schulze, who has, for the last six years, devoted himself to the study of the life history of the Adriatic sponges, and has many most important facts to our knowledge of animals."

## OBITUARY.

**Signor Giacomo Mechi.**—This well-known agriculturalist, whose death occurred on Sunday, 20th inst., was for many years a member of the Society of Arts, and served on the Council and on various committees. He died in London in May, 1880, and was the son of

Signor Giacomo Mechi, a native of Bologna. He commenced business early in life at a small shop in Leadenhall-street, and shortly afterwards invented his "magic razor strop." In 1840, he purchased the farm of Tiptree-hall, consisting of one hundred and seventy acres of inferior land, and at once proceeded to apply scientific principles to agricultural practice. He read the first of a series of papers on his farming operations before the Society on November 27th, 1850, and on March 7, 1860, a paper on "The Application of Town Sewage to a large Agricultural Area." He also joined in many discussions at the meetings, and contributed letters to the *Journal*. The last occasion upon which he spoke, was after the reading of Mr. J. C. Morton's paper on "Agricultural Experience," on May 8th of the present year. Mr. Mechi was a juror of the Great Exhibition of 1851, and of the Paris Exhibition of 1855. He was appointed Sheriff of London in 1856, and Alderman of Lime-street Ward, in 1858. On the failure of the Unity Bank, in 1866, of which he was Governor, he resigned his Aldermanic gown, much to the regret of his constituents and of his colleagues. Having determined to pay his share of the liabilities of the bank, which greatly crippled his resources, he felt he should be unable to bear the expenses of the mayoralty. Although Mr. Mechi had attained a good old age, there appears to be no doubt that his death was immediately caused by the misfortunes that overtook him at the end of his useful career. This naturally adds to the regret of the large numbers who now deplore his loss.

## GENERAL NOTES.

**Ink for Etching on Glass.**—An ink which can be employed for writing upon glass, has lately been brought out by Messrs. Sabatier and Co. It consists mainly of hydro-fluoric acid; but there are some other ingredients mixed with it, which enable it to be used as an ink, and which prevent the dangerous fumes which are found so inconvenient in using the simple acid.

**Electric Light.**—Mr. J. E. H. Gordon, according to *Nature*, has lately patented a method of producing light from electricity, based upon Mr. Spottiswoode's suggestion, to apply the alternating-current magneto-electric machine of De Méritens to the induction-coil. Mr. Gordon arranges small balls of platinum or iridium, or of an alloy of these metals, at the ends of fine platinum rods in pairs in the middle of a suitable globe, and causes to pass between them a rapid succession of sparks, whereby they are raised to incandescence. There is no consumption of carbon or any other substance, and the lamps may be connected either in series or in parallel branched arcs. The principal remaining disadvantage is the noise attendant on the rapid sparks. A mechanical contrivance is added to bring the knobs near together when no current is passing in the primary coil. The induction-coils used are of comparatively small size.

**Turin Industrial Museum.**—The Royal Italian Industrial Museum was founded at Turin, after the close of the International Exhibition, held in London, in 1862, and the collection for the purpose, made by the Royal Commissioner for Italy, were transferred to a large building, originally a convent, then a provincial college, and the office of the Minister of War, before the seat of Government was transferred to Rome. One of the departments of the museum is the *Archives Industrielles*, in which are preserved and classified the priced lists, illustrated catalogues, and technological pamphlets lately received from all parts of the world. The information contained in these catalogues is freely at the service of all who apply for it, and the authorities are desirous of receiving such lists from all who are willing to send them. The conservator of the museum, Chevalier Jarvis, was deputed to collect further objects at the Paris Universal Exhibition in 1878, when he received a large number of objects as gifts from exhibitors in the British Section, and from those connected with the British colonies.

## MEETINGS OF THE SOCIETY.

## ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

JANUARY 12.—“A Sanitary Protection Association for London.” By W. FREEMING JENKIN, F.R.S. On this evening Professor HUXLEY, LL.D., F.R.S., will preside.

JANUARY 19.—“Causes of Success and Failure in Modern Gold Mining.” By A. G. LOCK.

JANUARY 26.—“Five Years' Experience of the Working of the Trade Marks' Registration Act.” By EDMUND JOHNSON.

FEBRUARY 2.—“Trade Prospects.” By STEPHEN BOURNE.

FEBRUARY 9.—“The Present Condition of the Art of Wood-carving in England.” By J. HUNGERFORD POLLEN.

FEBRUARY 16.—“The Participation of Labour in the Profits of Enterprise.” By SEDLEY TAYLOR, M.A., late Fellow of Trinity College, Cambridge.

FEBRUARY 23.—“Recent Advances in Electric Lighting.” By W. H. PREECE, Pres. Soc. Tel. Eng.

MARCH 2.—“Flashing Signals for Lighthouses.” By Sir WILLIAM THOMSON, LL.D., F.R.S.

MARCH 9.—“Improvements in the Treatment of Esparto for the Manufacture of Paper.” By WILLIAM ARNOT, F.C.S.

MARCH 16.—“The Manufacture of Aerated Waters.” By T. P. BRUCE WARREN.

Dates not yet fixed:—

“Buying and Selling; its Nature and its Tools.” By Prof. BONAMY PRICE. On this evening Lord ALFRED S. CHURCHILL will preside.

“The Discrimination and Artistic Use of Precious Stones.” By Prof. A. H. CHURCH, F.C.S.

“The Compound Air Engine.” By Col. F. BEAUMONT, R.E.

“The Increasing Danger to Life and Property from Explosions.” By CORNELIUS WALFORD.

## FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

FEBRUARY 1.—“The Industrial Products of South Africa.” By the Right Honourable Sir HENRY BARTLE FRERE, Bart., G.C.B., G.C.S.I., D.C.L., LL.D., F.R.G.S., &c.

FEBRUARY 22.—“The Languages of South Africa.” By ROBERT N. CUST.

MARCH 15.—“The Loo Choo Islands.” By Consul JOHN A. GUBBINS.

APRIL 5.—“Trade Relations between Great Britain and her Dependencies.” By WILLIAM WESTGARTH.

## APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

JANUARY 27.—“A New Mechanical Furnace, and a Continuous System of Manufacturing Sulphate of Soda.” By JAMES MACTEAR.

FEBRUARY 24.—“Deep Sea Investigation, and the Apparatus used in it.” By J. G. BUCHANAN, F.R.S.E., F.C.S.

MARCH 24.—“The Future Development of Electrical Appliances.” By Prof. JOHN PERRY.

## INDIAN SECTION.

Friday evenings, at eight o'clock:—

JANUARY 21.—“Forest Conservancy in India.” By Sir RICHARD TEMPLE, Bart., G.C.S.I.

FEBRUARY 11.—“The Gold Fields of India.” By HYDE CLARKE.

MARCH 4.—“The Results of British Rule in India.” By J. M. MACLEAN.

MARCH 25.—“The Tenure and Cultivation of Land in India.” By Sir GEORGE CAMPBELL, K.C.S.I., M.P.

MAY 13.—“Burmah.” By General Sir ARTHUR PHAYRE, G.C.M.G., K.C.S.I., C.B.

## CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Second Course will be on “Watchmaking,” by EDWARD RIGG, M.A. Three Lectures.

February 7, 14, 21.

The Third Course will be on “The Scientific Principles involved in Electric Lighting,” by Prof. W. G. ADAMS, F.R.S. Four Lectures.

March 7, 14, 21, 28.

The Fourth Course will be on “The Art of Lacemaking,” by ALAN S. COLE. Three Lectures.

April 25; May 2, 9.

The Fifth Course will be on “Colour Blindness and its Influence upon Various Industries,” by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

May 16, 23, 30.

## MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 3RD.—British Architects, 9, Conduit-street, W., 8 p.m.

Institute of Actuaries, The Quadrangle, King's College, W.C., 7 p.m. Mr. F. N. Newcome, “The Simultaneous Construction of Compound Interest and Annuity Tables.”

Victoria Institute, 7, Adelphi-terrace, W.C., 8 p.m. Dr. Andrew Wilson, “The Past and the Present of the Cuttle Fishes.”

London Institution, Finsbury-circus, E.C., 5 p.m.

TUESDAY, JAN. 4TH.—Royal Institution, Albemarle-street, W., 8 p.m. (Juvenile Lecture.) Prof. Dewar, “Atoms” (Lecture IV.)

Pathological, 53, Berners-street, Oxford-street, W., 8½ p.m. Annual Meeting.

Biblical Archaeology, 9, Conduit-street, W., 8½ p.m. Annual Meeting.

Zoological, 11, Hanover-square, W., 8½ p.m. 1. Dr. Alfred Glinther, “The Account of the Zoological Collection made during the Survey of H.M.S. *Alert* in the Straits of Magellan, and on the Coast of Patagonia.” 2. Prof. Flower, “The Sea Elephant.”

WEDNESDAY, JAN. 5TH.—SOCIETY OF ARTS, John-street, Adelphi, W.C., 7 p.m. (Juvenile Lecture.) Mr. G. J. Romance, “Animal Intelligence.” (Lecture II.)

Geological, Burlington-house, W., 8 p.m. 1. Mr. C. Callaway, “The Archaeozoology of Anglesy,” with a Note on “The Microscopic Structure of some Anglesy Rocks,” by Prof. T. G. Bonney. 2. Mr. C. Callaway, “The Limestone of Durness and Assynt.” 3. Prof. T. G. Bonney, “A Boulder of Hornblende-Pikrite, near Pen-y-Carniog, Anglesy.”

Archaeological Association, 32, Sackville-street, W., 8 p.m. Dr. Wake Smart, “Notes on Roman Remains, from Nursling, Hants.” 2. Mr. G. R. Wright, “The Hardships of the Present Law of Treasure Trove.”

THURSDAY, JAN. 6TH.—Royal, Burlington-house, W., 8½ p.m. London Institution, Finsbury-circus, E.C., 7 p.m. Prof. Henry Morley, “Our Living Dramatists.”

South London Photographic (at the House of the Society of Arts), 8 p.m. Popular Lantern Display.

Royal Institution, Albemarle-street, W., 8 p.m. (Juvenile Lecture.) Prof. Dewar, “Atoms.” (Lecture V.)

Civil and Mechanical Engineers, 7, Westminster-chambers, S.W., 7 p.m. Mr. R. Harkness Twigg, “Accounts of Sombroero Islands, West India, with a Description of Sub-marine Quarrying of Phosphate of Lime.”

FRIDAY, JAN. 7TH.—Teachers' Association (at the House of the Society of Arts), 10½ a.m. Conference on Sir John Lubbock's Bill for the “Training and Registration of Teachers.”

Geologists' Association, University College, W.C., 8 p.m. Archaeological Institute, 16, New Burlington-street, W., 4 p.m.

SATURDAY, JAN. 8TH.—Royal Botanic, Inner-circle, Regent's-park, N.W., 8½ p.m.

Royal Institution, Albemarle-street, W., 8 p.m. (Juvenile Lecture.) Prof. Dewar, “Atoms.” (Lecture VI.)

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,468. Vol. XXIX.

FRIDAY, JANUARY 7, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## PROCEEDINGS OF THE SOCIETY.

## JUVENILE LECTURES.

Wednesday evening, the 5th inst, Mr. G. J. Es, F.R.S., delivered the second of his, on "Animal Intelligence." In continuation of the subject of his first lecture, he referred to the habits of bees and of trap-door spiders, and passed on to consider instances of the intelligence of the higher animals. He related anecdotes of reptiles (including tortoises, turtles, frogs, and lizards), birds (more particularly noting the habits of parrots), and mammals, beginning with the dog, whose sagacity the lecturer thought had been somewhat overrated, passing on to cats and foxes and wolves, and ending with monkeys, habits he was now studying at his own home. R. J. MANN, F.R.C.S. (the Chairman), in giving a vote of thanks to the lecturer, related an instance of the intelligent speech of a parrot at the meeting, and added that the human audience were not likely to prove less intelligent than the parrot, so he was sure that all the boys and girls present would join in heartily thanking Mr. Es for the two pleasant evenings they had enjoyed together.

## CANTOR LECTURES.

## POINTS OF CONTACT BETWEEN SCIENTIFIC AND ARTISTIC ASPECTS OF POTTERY AND PORCELAIN.

by Prof. A. H. Church, M.A. Oxon., F.C.S.

PART III.—DELIVERED DECEMBER 6TH, 1880.

*Stoneware and other Wares Glazed with Salt.*

Stoneware sometimes tends to pass into stone-ware.

A higher temperature of the kiln, and a proportion of vitrifiable material in the body, necessary conditions. And, if iron and substances tending to produce opacity and colour be added, stoneware may further advance into porcelain. But such transitions are

associated with many intermediate conditions, and it is impossible to define strictly what is earthenware, what stoneware, and what porcelain. In the two latter materials there must, however, be a binding vitrified cement produced out of the constituents of the body at the high temperature of firing. But the nature of the ware produced will depend upon so many factors, that to predict the result of burning any material or mixture is impracticable. The clays which form the basis of all ceramic materials differ immensely one from the other, and in many directions. The silicates of alumina, of which they mainly consist, are not always identical, much opal is present in some, while imperfect kaolinisation and, consequently, a high percentage of alkalies, characterise others; the proportion of iron forms another point of difference. The following analysis of different typical clays serve to illustrate the range of composition, but they by no means exhaust it:—

Percentage of	Stourbridge.	Watcombe.	Teignmouth.	Poole.	Cornwall.
Silica	66	58	53	50	46
Alumina	23	21	30	33	41
Alkalies, lime, } magnesia }	$\frac{1}{2}$	7	3	4	4
Oxide of iron	2	8	$2\frac{1}{2}$	$2\frac{1}{2}$	trace
Water	$8\frac{1}{2}$	6	$11\frac{1}{2}$	$10\frac{1}{2}$	9

It is particularly important to trace, wherever possible, the dependence on composition of the contraction on firing which clays undergo. It usually varies from 1 to 10 per cent. on the original volume. That silica, in most of its forms, reduces shrinkage has been long known, while the elaborate researches of Mr. George Maw, on the natural clays of the British strata, have given precision to our acquaintance with the effect of heat upon these raw materials of pottery, both in their native state, and when freed from coarse matter by washing.

In attempting to ascertain the relation between the constituents of stoneware bodies and their outward aspect, one meets with difficulties often insuperable, through the insufficiency of records, especially as to the "Grès Cérames" of foreign origin.

It is, indeed, only within the last few years that chemical analyses, with any claim to accuracy, have been attempted of British ceramic materials and products, and our determinations are still all too incomplete. Naturally, the manufacturers of to-day, like those of a couple of centuries back, are not ready to divulge the recipes, even if their differences be apparently trivial, which experience has shown to give the most satisfactory results. The manuscript memoranda of Wedgwood, and the published notes of Enoch Wood, Simeon Shaw, and others, have, however, left some record of the materials employed by our Staffordshire white stoneware potters of the eighteenth century. And we have, happily, an extensive series of their ceramic productions still extant for critical study, and for analyses of materials and methods. It is evident that there was a progressive improvement in the materials and

modes of making stoneware in the seventeenth and early part of the eighteenth century. This progress was not exclusively localised in Staffordshire, but was, perhaps, more marked in some other centres of the manufacture. As to the district of the potteries, Shaw states that the body of "crouch ware" was successively made of—

1. Brick-earth and fine sand;
2. Can-marl and fine sand;
3. Grey coal-measures clay, and fine sand;
4. Grey clay and ground flint.

This last and most important improvement is attributed to Astbury, in 1720; the son of this Astbury introduced in 1725 (upon a cream-coloured stone body) a wash of clay and flint. The ground flints were used in lieu of sand, and amounted from 20 per cent. to 25 per cent.

Flint, like sand, increases the hardness and lowers the fusibility of the paste or body, by diminishing the relative proportion of alkalies present. Later on, Josiah Wedgwood further modified and refined the stoneware body. His jasper ware contained more than half its weight of barytes or heavy spar (barium sulphate), while the proportion of clay to ground flint remained the same as before. Translated into per-centages, one of Wedgwood's own early recipes becomes—

	Per cent.
Barytes.....	57.1
Clay .....	28.6
Flint .....	9.5
Barium carbonate .....	4.8

Other and later recipes for this barytic body are—

Barytes .....	45	—	45
Kaolin .....	18	—	10
Blue clay .....	26	—	15
Flint .....	11	—	12
Gypsum .....	0	—	2
Cornish stone .....	0	—	16

In this jasper ware, the barytes acts in more than one way; for not only does it constitute one of the refractory ingredients of the body, but it forms an infinite number of minute internal reflectors, displaying to advantage any colours which may have been incorporated with the vitreous substance of the ware. Sometimes to barytes must be attributed the chalky and opaque whiteness which is seen in jasper bodies.

The introduction of felspathic constituents into the stoneware mixture alters it in the direction of greater fusibility and translucency. Felspar and china stone are used for this purpose; so high a per-centage of china stone as 40 is not unusual. The great contraction or firing which such stonewares and semi-porcelains undergo, form a considerable drawback to their common employment.

Thus far we have been considering the body or paste of stonewares. Before passing on to the study of the remarkable process of glazing them, a method not adapted for, nor applicable to, other wares, the definition of stoneware, as given by Jacquemart ("Histoire de la Céramique," pp. 7 and 386), may be advantageously cited. He speaks of "*les grès*" as having a dense, very hard, sonorous paste, made from plastic clay, "*degraisé*" by means of sand, silica, or pounded ware. He adds that they are usually glazed by means of salt, sometimes by felspar, forge scales, or pumice;

sometimes by a mixture of silica, felspar, and a little lead. The single baking which wares require lasts from four to eight days.

I will now turn to the glaze which consists so marked a characteristic of the majority of wares. It is peculiar, not only in its composition, but in its mode of application, its manner of action, and its appearance. Into its composition scarcely anything enters but soda and silica applied by means of vapour when the body glazed is at a high temperature; it is partly out of the silica of the ware and part of the vapour with which it comes in contact presents an appearance which differs from glazes, not so much in gloss as in texture, or in distribution on the surface where it has been produced. This texture reminds one of fine leather or orange-skin, but it varies in "grain" within very wide limits. The most characteristic elements are not generally the most beautiful; there is a tendency to excess or deficiency, and inequality of glaze, when produced by the same process, which causes great variations in the appearance of a single specimen. The perfection of glaze is sometimes reached on objects of common materials and ordinary workmanship, even drain-pipes, filters, and chemical apparatus. In the white Staffordshire stoneware of the eighteenth century, it is frequently seen to combine with efficiency as a protective coating with that external half-gloss which, without interference from excessive brilliancy on the one hand, or irregularity on the other, brings out both the form and the decoration of the body. The exact nature of the most perfect condition of this salt glaze baffles verbal description, but this, at least, is affirmed of it, that its individual particles are sufficiently obvious to prevent a completely uniform appearance being produced, must not be overlooked enough from each other to be numerable.

The chemical reactions concerned in the process of salt-glazing may next claim our attention. It will be convenient to speak first of the essential primary part of the change. This may be divided into two stages:—

In the first stage we have the vapour of common salt entering the furnace during the last stage of the firing, meeting with water-vapour arising from the combustion of the hydrogen of the fuel, and producing a normal constituent of the common air to the effect of 1 to 1½ per cent. by volume. The two vapours react, producing hydrochloric acid and soda, the former of which escapes almost completely, while the latter acts upon certain siliceous constituents of the hot ware, and thus forms sodium silicate and water. Questions arise as to the nature of the silicate thus formed, and the source in the body of the silica which combines with it. Some experiments lead to the formula  $\text{Na}_2\text{Si}_2\text{O}_5$  for the glaze, and seem to indicate that it is not all the aluminous silicates of the clay which combine with it, and part of the free silica, and alkaline silicates present, with which the soda vapours combines.

A subordinate or secondary reaction occurs between the hydrochloric acid, produced in reaction (a) above, and any ferric oxide present in the

body: we may formulate this in the following expression—

or we may assume that the common salt vapours act directly upon the ferric oxide thus—

If reaction *d* occur, there will be more soda to form additional glaze upon the ferruginous surface, while in both reactions, *c* and *d*, the ferric chloride, which is volatile, will yield, with water vapour, hydrochloric acid and ferric oxide, the latter then combining with the sodium silicate of the glaze to form a double silicate of iron and sodium. Thus, in the salt-glazing process, the iron of the body is brought in some measure to the surface, and contributes additional material to the glaze, while it imparts to it a brown hue. Impure clays, and those which are rich in lime, silica and alkalis, become much more highly glazed than a pure kaolin or china clay. Colouring materials with which the ware may be decorated act similarly. Even a wash of china clay upon a common clay will prevent the extra gloss, commonly formed on the latter, from being produced. Where red lead is mingled with the salt thrown into the kiln, first it is reduced by heat to protoxide, then lead chloride is probably formed, according to equation *c*, decomposed into lead oxide, according to *f*, and fixed on the ware as lead silicate, according to *g*:—

Before I take up the study of the individual specimens before us, it may be well for me to say a few words as to the early history of glazing with salt in this country. The subject is obscure. A manuscript by Josiah Wedgwood, dated 15th January, 1765, gives particulars furnished by one Steel, a potter, then aged 84, who remembered the brothers Elers, the Dutchmen, at work at Bradwell. Steel was one of those who went out to see what was the matter when the dense fumes rose from their salt-glaze kiln on the addition of the common salt, and he stated that glazing with salt was first employed by the Elers. Wedgwood agreed with this view, and further assigned to them the introduction of lathe and engine turning and of alabaster moulds. The old story about the origin of salt-glazing, about 1680, through the boiling-over of some brine in an earthen pot, lacks confirmation. It is extremely probable that the brothers Elers did first practise salt-glazing in Staffordshire somewhere between 1688 and 1693, but we are bound to admit the possibility of the process having been used elsewhere in England at an earlier date. As early as 1671, two English patents were granted for making stoneware. One of these, dated 23rd April, 1671, was in favour of J. Ariens van Hamme; the other, dated 13th April, in the same year, was that of J. Dwight, of Oxford. It was for the "mystery of porcelaine or china," and of "stoneware, commonly called Cologne ware." Fortunately, we possess a considerable number of authentic—we may almost say, dated—specimens of Dwight's stoneware. Some of these are earlier

than any pieces of Elers' manufacture, and yet exhibit all the characteristics of salt-glaze. The examples in the British and South Kensington Museums, all derived from the collection of Mr. C. W. Reynolds, may be cited as particular illustrations of my statement. But my own examination of a bust of Mrs. Pepys, and of a fine statue of Saturn (both, alas, now lost in the fatal fire of June, 1873, at the Alexandra Palace, when so many ceramic treasures perished), led me to the same result. The specimens discovered on the site of the Fulham works, by their present proprietor, Mr. C. J. Bailey, afford further confirmation of my view.

Thus far I have been directing your attention in succession to stoneware bodies; to the glaze with which they are commonly covered; and to the introduction of that peculiar method of glazing into this country. A few words as to certain salt-glazed stoneware vessels, to which an English origin is assigned by some authorities, may be fitly added now. These wares may be classified thus:—

*Class 1.*—Brown mottled jugs, often mounted in silver, bearing English plate marks of the Elizabethan period, 1558 to 1603. As "wasters" of these have been found in London, and as they seem to occur almost wholly in England, they, or some of them, were probably made in this country. If so, salt-glazing must be put back more than one century.

*Class 2.*—The narrow-necked jugs of brown-glazed ware, with a grotesque bearded head in front, known as "Bellarmines." These were certainly made by Dwight, of Fulham, but there seems no direct evidence to prove that any of them were made in England before the year 1671. Yet, if an English origin be accepted for some of the vessels belonging to class 1, there will be no difficulty in reaching a similar conclusion concerning examples of the present class.

*Class 3.*—Wide-mouthed jugs and cylindrical mugs, bearing applied medallions, with W. R., A. R., G. R., in front, and decorated with incised and applied ornaments, sometimes with cobalt blue and manganese purple upon the designs. These vessels are of drab or pale-brown or grey stoneware, and are salt-glazed. Those of early date, which are most elaborate and well finished in design and colour, can hardly be regarded as English, for the evidence of authentic examples, found at Fulham, does not point to any very high level of artistic excellence having been attained even there, towards the close of the seventeenth century, in this particular class of wares. But notwithstanding this limitation, I am convinced that some good pieces belonging to this third class were really of home manufacture. These are generally without colour, and of somewhat simple if not rude style.

*Class 4.*—This class consists of white stoneware jugs, usually of half-pint capacity, having a rough medallion in relief of W. R., A. R., or G. R. in front, and often further decorated with simple and rough leafage in dull blue. The glaze is smooth and not produced with salt. The body is not so hard as that of the preceding classes. These vessels are English, but the places of their manufacture can only be conjectured from documents and from "finds" of wasters. Three or four places within the London district have been suggested as the sites of the pot-works where these jugs were made,

but the question is one on which I must not further dwell just now.

Leaving these matters, about which a considerable degree of doubt still hangs, I will now pass on to the study of the most beautiful of the finer original wares ever made in this kingdom, a ware which is peculiar to England and to Staffordshire, and upon which, for about 80 years, an extraordinary amount of skill was exercised. It is remarkable, however, that the Staffordshire potteries no longer remain the seat of the salt-glazed stoneware manufacture. But in the period of 1688 (or 1693) to 1780, an immense quantity of "useful" ware of this kind was made in Burslem and "the Potteries." The question is naturally asked, "Did the Brothers Elers introduce and make it?" That they made this ware we have an argument in the identity of much of the ornament on "red china" of Elers' type with that on early white salt-glazed ware. We have the argument derived from the Continental "tincture," or feeling, which is observable in the impressed and applied ornaments of the ware. We have a consensus of local tradition almost without exception. The authority of Wedgwood, and of other potters of the middle and latter part of the eighteenth century, tends in the same direction. Enoch Wood's ceramic museum contained a large collection of this Staffordshire stoneware, described in Ward's "Stoke-upon-Trent" (1843) as including examples of "the Dutchmen's superior skill." One of the specimens was a pint jug, bearing a medallion of King William III., in relief, accompanied by flowered ornaments stamped in metal moulds; the body was of ash-coloured marl. This jug is spoken of as the earliest specimen of salt-glaze in the Wood collection. It is a great pity that this museum was dispersed; some of the specimens are fortunately preserved in Jermyn-street, and at South Kensington; some are in Edinburgh and Dublin, but the best were given by Enoch Wood to Dresden, while others form part of a private collection in the Potteries. Enoch Wood, however, according to the catalogue of his collection, deemed the white and grey stoneware pieces to have been imported from Germany or Holland. But there is irrefragable evidence to the contrary. As to vessels of 1700 and later, there is no dispute. Enoch Wood possessed a number made of Staffordshire clay, marbled with manganese, glazed with salt, and bearing medallions of Queen Anne; he speaks of these as "chased." Then were introduced slips of Devon or Dorset clay to line or wash or ornament the wares; afterwards the admixture of native clays with flint, then metal moulds, and lastly those of plaster of Paris. We are enabled from these particulars, and from the data which I furnished at the opening of this discourse, to construct a kind of rough chronological division of Staffordshire work in salt-glazed stoneware:—

Period I.—Prior to 1720—Impressed and applied ornaments; ash-grey and dull bodies.

Period II.—1720 to 1740—Flint introduced into the body; fine sharp work.

Period III.—1740 to 1760—Extensive use of coloured enamels in decorating the salt-glazed surface.

Period IV.—1760 to 1780—Prevalent ornamentation of basket and perforated work.

The decoration of the ware comprised a great

variety of processes, which may be summarised in the following scheme:—

Form.	Engine turning.
	Incised work.
	Applied ornaments cast in moulds.
	Pressed or moulded work.
Colour.	Slip-cast in absorbent moulds.
	Ash-body with white-wash cut a partially, or with applied ornaments.
	Zaffre or manganese powdering prepared to glazing.
	Enamelling over glaze.
	Transfer printing over glaze in iron or gold violet.
	Oil gilding and japaning.

It should be noticed that the whiteness of the specimens of old Staffordshire stoneware is a some measure to the wood fuel employed for firing them, and to the protection of saggars. Doulton has kindly refired this old plate for me without a sagger, and in one of his ordinary ware kilns. It stood the test well, not having suffered in form by the fiery ordeal to which it has been subjected. But the colour of the surface has been darkened by irregular brownings of the trial. The trial was a severe one, not only for the reason previously given, but because when a piece of stoneware has been once glazed with salt, the fusible matter then present on the surface is liable to destroy the refractory character of the body at a second firing.

[The lecturer proceeded to point out the physical and artistic characters of a large series of Staffordshire specimens on the table.]

The modern revival of English stoneware has been so fully dwelt upon in this hall by Mr. Spence, that I need do little more than name it. But it is impossible to pass over quite in silence the marvellous spirit with which Mr. Henry Doulton and those whom he has associated with him in the work, have developed an art manufacture of very high order of excellence out of a large works, long devoted to the production of very cheap but very humble wares. He has pressed in service every element, tried and untried, and could be brought into the manufacture, and the results are widely known and appreciated.

[The lecturer proceeded to point out the distinctive and physical characteristics of a selection of pieces of Doulton's stonewares, including those without glaze, those having a glaze essentially felspathic, and those glazed with salt. He dwelt with especial emphasis upon those specimens which showed beautiful effects of colour and texture to accidental flowing, mingling, &c., of colours, and to the contrast between glazed and unglazed or partially glazed surfaces.]

The flattery which shows itself in imitative followed the stoneware revival of Messrs. Doulton. The productions of Mr. C. J. Bailey, of Fulham; Messrs. Stiff and Sons, of the London Pottery; Lambeth; and of Mr. R. W. Martin, of Stoke-upon-Trent, resemble the pieces emanating from Messrs. Doulton's works in character and manner, but are, perhaps, of a less sustained order of excellence. But, whatever their source and spring, and ever limited in the range of their artistic elements, the products of all the potteries which I have named present many features of value and interest.

take a remarkable tribute to the splendid well-deserved success of the originators of this art-manufacture.

A lecture on stoneware could omit all reference to the productions of Continental potteries. But brief limits of the time remaining at my disposal forbid more than a hasty glance at a few of the most characteristic kinds of German and Dutch stonewares. The study of the specimens in the British Museum and in the Dutch Museum will enable any one interested in the subject to discern the peculiarities and, I may add, the series which distinguish the four most important kinds:—

*Class I.*—White cannettes, glazed and unglazed, belonging to the latter half of the sixteenth century, and resembling in body the white stoneware of the first period. They are chiefly decorated in relief.

*Class II.*—Yellow and brown short jugs, usually with acorn and oak leaf patterns in high relief, and referable to the close of the fifteenth century and the beginning of the sixteenth century.

*Class III.*—Jugs, tankards, &c., of greyish or body, variously decorated with incised and relief ornaments, and frequently further enriched with cobalt-blue and manganese-purple; often attributable to Cologne and Aachen districts. Similar incisions have been traced to Beauvais, in France.

*Class IV.*—Tankards, jugs, and other vessels of stoneware, with dark brown or black glaze, decorated further (in the enamel kiln) with various colours, sometimes gilt also. They are of Franco-German origin; Jacquemart gives as the city of this manufacture, Creuse, in France. Sometimes the wares of this class have a "rusty" look, but the simpler decoration they occasionally bear, of a white stanniferous enamel on a purplish black ground, is characteristic.

The lecturer concluded by describing the chief statistics of the foreign stone wares which he brought to illustrate his discourse, pointing out the most commendable features of foreign specimens, and how the modern reproductions fail to satisfy the feeling for style and texture.]

## MISCELLANEOUS.

### REPLY TO MR. A. J. ELLIS'S PAPER ON "THE HISTORY OF MUSICAL PITCH," AND APPENDIX.

My paper on "The History of Musical Pitch" is in the *Journal of the Society of Arts*, for 5 March, 1880, pp. 293—336, and the Appendix, containing a list of the principal errors of the press in the paper, and several additions, is printed in the *Journal*, 2 April, 1880, pp. 400—403. In reprinting for private circulation, I was able to make a few additions, and, at the last moment, an important addition respecting the pitch of Koenig's Ut, App. A. 2, which I am desirous of printing with still in the *Journal*. I have also been able to make experiments on the influence of temperature on the pitch of harmonium reeds, which, as I stated

(*Hist. of M. P.*, p. 301, col. 2, end of art. 19), was unknown when my paper was read, and is important for the use of Appunn's tonometer. I have also received some corrections respecting the Temple organ, and an important addition respecting the Strasburg Minster organ. These and one or two other points will be given in this postscript, which has been delayed by the pressure of other work.

#### CORRECTIONS AND ADDITIONS.

(1.) *Handel's Fork*.—Page 293, col. 2, note, the Rev. G. T. Driffild, owner of Handel's fork, has removed from the rectory of Bow to that of Old, near Northampton.

(2.) *Influence of Temperature on the Pitch of Harmonium Reeds*.—Page 301, col. 1, last paragraph of art. 19, l. 4, I stated that one of the drawbacks to Appunn's reed tonometers was, that "their variation with temperature was unknown." I have now been able to make at least a close approximation to its determination. In finding the pitch of every reed in Appunn's instrument, as described on p. 301, col. 1, in November, 1879, I worked at a variety of artificial temperatures, from 53° F. to 60° F., all carefully recorded for each reed, together with the numbers of the Scheibler forks with which the beats were taken, and also the precise numbers of beats observed. It occurred to me that by measuring about a dozen of the same reeds of very different pitch, at a much higher temperature, by means of the same forks as before, I should have sufficient data for calculating the amount of alteration for a reed of a given pitch, when subjected to a known variation of temperature. I accordingly took the pitch of a selected number of reeds on one day in July, and two days in September, 1880, at constant natural temperatures of 71½, 73, and 79 deg. F. respectively. I had in each case to allow for the alteration of the pitch of the forks by temperature, and then to determine the pitch of the reed at the higher temperature, and finally to divide the result by the pitch of the same reed at a lower temperature, and by the number of degrees of difference of temperature. As at least ten observations were taken with each fork, and at least two, sometimes three, forks were used for each reed, and the means of each were taken for safety, the calculations were rather lengthy. The resulting figures will appear in a paper in the Proceedings of the Royal Society, where also has appeared my paper on Musical Beats (vol. xxx., pp. 520—533) in which I have given some of the details of my examination of Appunn's tonometer. The mean result is that both tuning forks and harmonium reeds flatten by heat, and sharpen by cold; but while forks alter by about 1 vib. in 20,000, the reeds alter by about 1 vib. in 10,000 (that is, twice as much) for each degree Fahrenheit. This correction should therefore be also made in taking pitches by Appunn's tonometer. Practically if a fork, an harmonium, and an organ were in exact unison, as A 440, at 59° F., then if the temperature were to rise 20° F., as is not unfrequently the case during an evening concert, the fork would flatten to A 439.66, and the reed to A 439.12, whereas the organ would sharpen to A 449.15, which would be terribly out of tune with the harmonium, so that no music should be written, as music has been written, for organs and harmoniums to play together.

(3.) *French Pitch at Covent-garden Opera in 1880*.—Page 314, col. 1, after line 7, add—At Kube's concert on the 12th of June, 1880, Mr. Hipkins observed that the Covent-garden opera band was in exact unison with his piano there used, which piano had been carefully tuned in French pitch. Quite at the close of the Covent-garden opera season of 1880, he observed that the band had sharpened by three or four vibrations. Hence, the intention to use French pitch was fairly carried out, and the effect of French pitch in operas was well exhibited.

(4.) *Handel's Pitch*.—Page 319, col. 2, line 20 from bottom, correct the date of Mr. Brownlow's letter to

21 May, 1858, instead of 1848. Mr. Driffield did not own the fork till 1857.

(5.) *Pitch of the Ancient Concerts at Hanover-square Rooms.*—Page 320, col. 1, l. 6 from bottom of first paragraph, it is stated that in 1805 the organ of the Hanover-square Rooms was built by Elliott “in the usual flat pitch of the period (that is about A 422·5.)” The fork to which that organ was originally tuned was subsequently found by Messrs. Hill, the successors of Elliott, and kindly lent to me for measurement. Hence on p. 321, col. 1, alter the entry A 424·9 to (1) A 424·9; and insert as a new entry :—

(2) **MA 424·9**, MC 508·3, 1 D 568·3 measured (Ellis) 1805. Old D-fork of Elliott’s, to which he tuned the organ he built for the Hanover-square Rooms, lent by his successors Messrs. Hill, showing that the estimate under (1) A 422·5 near the end (which see for other particulars) was only V 2·5 too flat. If we calculate from 1 D we find 1 EC 506·3, but if we calculate from MA we find 1 EC 505·3.

Insert among concert organs, p. 334, col. 2, “1805, Elliott, Hanover-square Rooms, S 2·39, A 424·9.”

(6.) *Organ of St. Mary’s, Shrewsbury.*—(2) **MA 433·6**, l. 2, for Byfield and Green, read, John Harris and John Byfield, 1729, the makers names originally painted on the organ, altered by Blyth, 1826, and by Brewster and Fleetwood, 1833, and in line 3, for 1840c, read 1847. This information was supplied by Mr. Hiles, 61, Elaham-road, Kensington, W. Make the corresponding change on p. 334, col. 2.

(7.) *Fork of Society of Arts (copy).* Page 328, col. 2, entry (5) **EA 448·0**, for C 332·8 read C 532·8.

(8.) *Strasburg Organ.*—See p. 306, col. 2, l. 20, from bottom, and p. 317, col. 1, l. 11 from bottom.—There is here an attempt to estimate the pitch of A. Silbermann’s celebrated organ at Strasburg, which I inclined to put at A 395·8. After much correspondence, and a long delay, I have at last succeeded in obtaining the pitch of this interesting instrument, through the kindness of Mr. Hipkins, in London, and of Miss Sydney Austin, M. Stockhausen, Director of the Conservatoire, Messrs. Hug frères, musicellers, Wetzel, the organ builder, and the Abbé Schäffer, organist of the Minster, all of Strasburg. Hence, insert as a new entry on p. 371, col. 2, immediately after A 392·2 :—

**A 393·2**, MC 470·4, JC 471·8, 1 EC 467·6 measured, S1·04 (Stockhausen and Ellis) 1713-16. Great organ at Strasburg Minster, built by A. Silbermann. A fork was sent to Strasburg by Mr. Hipkins, and the beats it made with the 1 C of the organ were counted by M. Stockhausen at 16·5 deg. Réaumur. This fork was then measured by me, and the direction of the beats being known by other forks, the pitch of the 1 C at this temperature was determined. It was then reduced to the pitch at 59° F. in the usual way. The Abbé Schäffer informed me that the temperament is now equal, this tuning having been introduced about 1830 by M. Weichmann, when the “echo organ” was increased and placed above in the vault of the church. After the Franco-German War, during which the organ was partly destroyed, it was restored and tuned equally by M. Wetzel. But in every case the pitch of A was preserved, as it was in the original church pitch of A. Silbermann. Then, as 1 C was measured, 2 EA was calculated from it as an equal minor Third lower, which therefore, gave the original pitch, A 393·2, whence the original meantone C 470·4, and just C 471·8 were calculated. The result is probably correct to one or, at most, two vibrations. The pitch is S1·78 flatter than French pitch, which is about halfway between S1·50 (or the three-quarters of a tone estimated by ear by M. Stockhausen and M. Wetzel) and S2·0 (or a whole tone, as estimated by Mr. Hopkins), showing that their estimates were both tolerably correct, for musicians seldom estimate closer than to a quarter of a tone. This organ labours under the defect—which, according to Mr. Davison (of Gray

and Davison), was not unfrequent in old org having unequal force of wind, entirely out control of the player, and often altering in notes to the extent of a quarter of a tone. Th intention to contruct a bellows with equal press re-tune the organ thoroughly, in strict equal t ment, when funds allow. It will be observed is a B French-foot-organ, as a mean semiton than its MC 470·4, calculated above, gives M which is almost exactly 450·5, or Bédos’s C pipe one French foot in length (see p. 317 MA 376·6). It is the most exact specimen French-foot-organ which I have found, and confirms the pitch assigned to Bédos but the of the present determination. This pitch also within a vibration, with Euler’s clavichord, A: nearly the same date (1739), and with Dr. determination of the pitch of Trinity College after flattening, MA 395·2. The close agree the pitch of the organs cited under *Church Pits* to which this belongs, puts the actual use of thi in various countries 150 to 200 years ago beyo reasonable doubt.

(9.) *Comparison of Scheibler’s, McLeod’s and Measures.*—Appendix, p. 401, col. 2, l. 32, o found also,” to the end of the table, and in following, which results from measurements m sequently to printing the Appendix, but is give private reprint :—

Making the corresponding corrections, the n Prof. Mayer’s measurements are given in the “Mayer, E.” below. Afterwards Prof. measured the forks with the points on, and th the points off, each fork remaining unmover vice for both measurements. It was thus di that the effect of the added points was ve indeed, and that the chief difference general from some loss the forks had sustained in their to America and back, as shown below, the being fractions of V (or the numbers of vibrati second).

Forks.	Conserv.	Tuileries.	Feydeau.	Versailles.

Adding these sums to the values found t Mayer, we find his measurement of the forks in dition in which they were when measured b McLeod and myself at 59° F. The results are the column, “Mayer, McL.”

Name of Fork.	McLeod.	Ellis.	Mayer, E.
Conservatoire....	439·55	439·54	439·48
Tuileries .....	434·33	434·25	434·26
Feydeau .....	423·02	423·01	422·91
Versailles .....	395·83	395·79	395·77
Marloye .....	255·98	255·96	255·98

The second table on p. 300, col. 1, which wa complete, must be supplemented accordingly. 401, col. 2, l. 11 from bottom, for two read tl l. 7 from bottom, for his own fork, V 256·31, own forks, V 256·28, 256·31, and p. 402, l. read 10. The above corrections were made in th reprint.

(10.) *Koenig’s New Standard Fork.*—Page 405 after the paragraph ending on l. 4 add the follo

It of the various measures of Koenig's  $U_t$ , p. 401, col. 2, near bottom, was to make it probable that this fork, which was held to 256, really gave  $V\ 256\cdot28$  at  $59^\circ\text{ F.} = 15^\circ\text{ C.}$ , as the temperature at which it was supposed to be constructed, although Koenig had never a temperature for which his forks were correct. able on p. 301, col. 2, I had calculated the of  $V\ 64\cdot07$ , or two octaves lower, on this (to which should have been added the 12th or Sol, 768·84, which was accidentally last July, in measuring a series of forks by Messrs. Valentine and Carr for Lord intended to give  $V\ 128, 160, 192, 256, 320, 768, 1024, 1280, 1536, 2048$ , I had an carefully remeasuring all Koenig's harmonic ng to the Royal Institution, and I found vibrations agreeing exactly with those in red to. Since no reasonable doubt could be correctness of these determinations, it that Koenig's fork was not intended for a  $59^\circ\text{ F.}$  but for one of about  $80^\circ\text{ F.}$

300, col. 2, l. 11, I stated that I had Koenig had "invented a new and exceedingly accurate counting instrument," of which, at the ing my paper, I had seen no description. d was enabled to lend me Koenig's paper, ons of the Vibrations of a Normal Tuning-ernachungen über die Schwingungen einer agabel, from the *Annalen der Physik und 30, Neue Folge*, vol. 9, pp. 391—417, editedemann, Leipzig) in time for me to insert a ript, on 1 May, 1880, in my private owing that these researches had removed all discrepancy between him and me, and that now ally different methods of Scheibler, McLeod, ad Koenig (to which we may add Appunn perly corrected) all led to the same result; so re at last able to determine pitch with great and all the determinations made by myself in story of Musical Pitch" may be trusted as Dr. Koenig has subsequently kindly pre- with a copy of this paper, and a photograph of instrument. His process and results are as

be constructed a very large tuning-fork, giving dy 64 double vibrations in a second. The tang of this fork was firmly fixed permanently in a wing part of a solid stand, kept truly horizontal adjusting screws, and supporting a frame con- clock, which was wound in the usual way, but ated by the vibrations of the fork, instead of a pendulum. Its second hand, therefore, was gister 128 single vibrations in a second. By of this clock was another, a chronometer, an time accurately, so that it was easy to see re tuning-fork clock had lost or gained in a ber of hours. As each hour of the tuning- corresponded to  $60\cdot60\cdot64 = 230,400$  double and  $60\cdot60\cdot128 = 460,800$  single vibrations, comparatively easy to calculate, by a careful of the two clocks, the exact number of single vibrations made by the fork in one is, its pitch, to a degree of accuracy hitherto Each prong was furnished with micrometer rying heavy knobs, and, by screwing these n, the pitch could be varied, and finally ad- justed to  $V\ 64$ . A long thermometer hangs ock between the prongs without touching ng accurately the temperature of the air, sufficient time (determined by careful ob- of the fork itself, which, being a heavy mass re some time to show any effects of a change re. To one of the prongs was attached as of a microscope, of which the body and re attached to the frame, thus forming a bration microscope. The weight of this

object-glass was balanced by a steel mirror on the other prong, added for the purpose of producing the Lissajous changing figures, by means of which forks can be accurately tuned to one or two Octaves, or to a Third or Fourth, or even Sixth, above the normal fork. On account of the slowness with which the fork followed the temperature, so that, when depressed by  $V\ 2$ , by heating, it took from two to two and a-half hours to thoroughly recover its former rapidity, it became necessary to operate as much as possible in a constant temperature. But there were great difficulties in keeping up an artificial temperature day and night. Large underground vaults were too cold, being only  $12\text{ C.} = 53\cdot6^\circ\text{ F.}$  in Paris, where the experiments were conducted. Dr. Koenig therefore selected  $20^\circ\text{ C.} = 68^\circ\text{ F.}$  as his normal temperature, and conducted his experiments in a very large, lofty, and completely closed room, in which temperature altered but slightly, so that the thermometer from morning till night showed scarcely any changes, especially in sunless days, of which he had abundance in Paris in 1879, and he obtained six days in June, and one in September, in which he was able to tune the fork to  $V\ 64$ , at  $20^\circ\text{ C.}$ , during four to eight hours. By these means he obtained, for the first time, an absolute standard for future deductions.

Then he tuned, by the Lissajous figures, another fork to  $V\ 256$  at  $20^\circ\text{ C.} = 68^\circ\text{ F.}$ , and by the same process ascertained that its vibrations were absolutely isochro- nous, which is not always the case when the fork is attached to a resonance-box. Although, in my own experiments, I was not able to find any sensible amount of change which might not be fairly attributed to rrors of observation, Dr. Koenig, by the application of the vibration-microscope, was able to detect very small differences, amounting to  $V\ 0\cdot167$  in some cases, an amount absolutely inappreciable by ordinary methods of observation.

Dr. Koenig made a series of most important observa- tions on the influence of temperature upon the pitch of tuning-forks, and his conclusion was that "we may say, quite in general, that the number of vibrations made in a second by a tuning-fork varies by one in 8,943 vibrations for one degree Centigrade" = one in 16,097 for  $1^\circ\text{ F.}$  But different forks are affected dif- ferently, and, as his standard  $V\ 256$  at  $20^\circ\text{ C.} = 68^\circ\text{ F.}$  varied by  $V\ 0\cdot286$  for  $1^\circ\text{ C.}$  or  $V\ 0\cdot16$  for  $1^\circ\text{ F.}$ , it altered by one in 16,000. The different determinations of the variation of tuning-forks by temperature hitherto made are as follows:—

One in 17,850 or 16,970 by Cavallé-Coll	for $1^\circ\text{ F.}$
" " 20,000 or 16,670 by Scheibler	"
" " 20,250 or 18,000 by Kayser	"
" " 18,280 from $59^\circ$ to $175^\circ\text{ F.}$ by A. J. Ellis	"
" " 20,490 by Prof. McLeod	"
" " 22,000 by Prof. Mayer	"
" " 21,000, as the mean of the two last,	"
" " 16,087 or 16,112 or 16,000 by Dr. Koenig	"

The differences for the same observer, arise from the use of different forks, and Dr. Koenig's are founded on the longest series of careful observations; so that, for his forks, his numbers—or, say, one in 16,000 for each degree Fahrenheit—should certainly be adopted.

Dr. Koenig then took his old standard fork  $U_t$ , in- tended to give  $V\ 256$ , and comparing it with his new standard at  $20^\circ\text{ C.}$  he found that at that temperature it gave  $V\ 256\cdot1774$ . Reducing this to  $15^\circ\text{ C.} = 59^\circ\text{ F.}$  we have to divide by 16,000 and multiply by 5, giving  $V\ 1\cdot44$  which has to be added, so that according to Dr. Koenig's own reckoning, his  $U_t = V\ 256\cdot3215$ . But using the co-efficient of one in 21,000 for  $1^\circ\text{ F.}$  by which I had calculated (p. 297, col. 1, line 23 from bottom), we should have to divide by 21,000 and multiply by 9, giving  $V\ 1\cdot098$  to be added, and giving the result  $V\ 256\cdot2872$ . Either result,  $256\cdot32, 256\cdot29$ , differs imperceptibly from the  $256\cdot28$  at which I had arrived by the measurements of 10 different copies (app. p. 402, col. 1, line 2). Hence all discrepancy between

him and myself ceases. As  $256 \div 800 = .32$ , and  $256 \div 900 = .28$ , we can readily reduce Dr. Koenig's old standards to  $15^{\circ} \text{C.} = 59^{\circ} \text{F.}$  by adding the 800th or 900th part. Taking the coefficient as one in 16,000 for  $1^{\circ} \text{F.}$  according to Dr. Koenig's determination, and the value at  $59^{\circ} \text{F.} = V 256.32$ , we should find that the temperature at which the fork would give  $V 256$  would be  $79^{\circ} \text{F.}$ , which agrees with Koenig's  $26.2^{\circ} \text{C.} = 79.16^{\circ} \text{F.}$  Taking, however, my value  $V 256.28$ , and my coefficient of one in 21,000 for  $1^{\circ} \text{F.}$ , we should find the temperature  $80.8^{\circ} \text{F.}$  In this particular case no doubt Dr. Koenig's determination of the coefficient as one in 16,000 for  $1^{\circ} \text{F.}$  should be assumed. The differences are extremely small, and depend entirely upon the uncertainties involved in the determination of the influence of temperature on forks. To avoid the trouble of calculating the correction for temperature, Dr. Koenig has affixed an apparatus to the end of his standard fork which may be adjusted to temperature, and will then secure  $V 256$  at all temperatures.

Dr. Koenig proceeded to find the real pitch of the French diapason normal in the Conservatoire (see p. 323, col. 2, under A 435.4). He first constructed, by beats at  $20^{\circ} \text{C.} = 68^{\circ} \text{F.}$ , a fork  $V 5$  sharper than his new standard,  $V 256$ , giving  $V 261$  at  $20^{\circ} \text{C.}$ ; then, by Lissajous' figures, he constructed a fork forming the exact interval of a major sixth, or  $3:5$  with it. This was  $V 435$ , at  $20^{\circ} \text{C.}$ , but the intentional pitch of the diapason normal was  $V 435$  at  $15^{\circ} \text{C.}$ , and the fork just constructed would give  $V 435.243$  at  $15^{\circ}$ , according to Dr. Koenig's calculations, where he assumes the coefficient as one in 8,951 for  $1^{\circ} \text{C.}$ , or one in 16,112 for  $1^{\circ} \text{F.}$  Hence he constructed by beats a third fork,  $V 243$  flatter than the former, and obtained a real  $V 435$  at  $15^{\circ} \text{C.}$  (such a fork Koenig had already constructed, unintentionally, and probably not quite so truly, see p. 323, col. 2 (6), A 435.0). This new fork he took to the Conservatoire, and left it for some days beside the diapason normal, in order that both might acquire the same temperature, and then, taking the beats, he determined the diapason normal as  $V 435.45$ , but says he could not feel absolute certainty, as the diapason normal would not give beats for more than 20 secs., owing, he thinks, to the action of the resonance box to which it is attached, so that for perfect accuracy it would be necessary to remove it. But, he adds, "Such extreme accuracy would not be of very great interest, because the experiments by which its pitch at  $15^{\circ} \text{C.}$  was determined, have not been published." The statement of the method used, which I have given, p. 323, col. 2, under A 435.4, was made on the authority of M. Cavallé-Coll. I had previously endeavoured, without success, to learn the method from M. Lissajous, who was responsible for the pitch, but is now dead. This determination,  $V 435.45$ , made with such immense care and trouble, agrees almost precisely with mine,  $V 435.4$ ; but as no provision had been made in the measurements by Mr. Hipkins and my son, for bringing the measuring fork to the temperature of the diapason normal, the process was in no respect so trustworthy as Dr. Koenig's. The near agreement of the result, however, tends to confirm the accuracy of my determinations of pitch. It is impossible to read Dr. Koenig's paper, which I have just summarised, without feeling the utmost confidence in his results, and admiration for his ingenuity, accuracy, and perseverance.

(11.) *Compass of Voice*.—Page 420, art. (3), l. 7 from end, for  $\frac{1}{2} \text{ F } 135.2$  read  $\frac{1}{2} \text{ F } 1352.0$ . Corrected in my private reprint.

(12.) *Lavenham Bell*.—App. p. 402, col. 2, art. (7), l. 10 from end, omit from Mr. Hermann Smith to the end of the paragraph, and insert (the correction was made in my private reprint, after Mr. Lewis had compared a measured fork I sent him, with the little harmonium from which he had estimated the pitch):—

Mr. Lewis, the organ builder, found the famous old tenor bell at Lavenham (16½ miles W.N.W. of Ipswich),

date 1625, meant to be and called D, to be 2 D 2 giving MA 431.3, which would be rather sharper than Harris's A 428.7 at Newcastle-upon-Tyne (p. 322, c) and is interesting, as occurring in the earliest di mean pitch, and before English organs had been sm by the Puritans, 1644—6.

(13.) *Temple Church Organ*.—The indication Appendix No. 9 (p. 402 of original, and p. 403 (print) contain several errors, and should be replaced by the following, in which the parts in inverted commas are arranged from communications from Messrs. F and Andrews, organ builders, Hull, who last r the organ. Insert on p. 327, col 1, after \*A 444.3

\* (2) A 444.3, B flat 471.4, B 498.6, C 529 all mea (Ellis), 1880, London; Temple Church organ, after organ had been rebuilt in 1877-8, by Messrs. Foste Andrews, who found the pitch "to be a good flat to the Society of Arts fork, which pitch is st maintained." The fork mentioned was a copy by Metze was measured by me at C 532.2, which is perce sharper than the existing C 529, agreeing with a "No transposition of pipes was made by Messrs. F A. during the rebuilding. The organ was origi in the eastern arch of the round church, whence it removed in 1840-41 by the Mr. J. C. Bishop, (d. 1 and re-arranged and erected in 1843 in the chamber, where the present instrument stands, the being taken out of a window in the choir, and a organ room constructed. On commencing the mu finishing, the whole of which was done in the ell and on the old sound boards" (consequently ret the old quarter tones, E flat and D sharp. A flat sharp, as originally at Durham, see p. 330, col. 2 line), "the pitch was found to be very sharp sharp by more than a quarter of a to that the transposition of one pipe was not su to make it equal to the pitch then in use hence, on account of the quarter-tones, Mr. Bishop determined to transpose two pipes upwar insert two new pipes in each stop. This work was by Mr. Forster, sen." Now here arises a dif Mr. C. A. Bishop (son of Mr. J. C. Bishop) b that his father always used "Smart's pitch," wh 1843, ought to have been A 433, MC 518, see col. 2, but may have been Smart's old pitch, wh the original Philharmonic pitch, see p. 320, col. 423.7, C 506.8. This agrees with Mr. Clarke' ment that the Temple organ was in exact with Handel's fork, see p. 319, col. 2 (1) A 422 but then Mr. Clarke's statements respecting the of the ancient concerts as being a whole above this pitch, have been entirely discredited (a lines of same entry). Messrs. F and A. say the organ was, in 1843, "finished to a fork supposed 512." But, considering that at about this time C was believed to be C 512 (see p. 326, col. 1, A 44 which would be manifestly far too sharp, possibly C or C 507, might also have been supposed to be C It is clear, however, that the organ was lower more than a quarter of a tone. If we take Mr. C to be right (and he could hardly be much wrong unison, although liable to errors arising from uns temperature), Mr. J. C. Bishop left the org A 422.5 MC 505.4, having probably found it at A 4 B. Schmidt's Hampton-court pitch (p. 326, col. 1), v is S 77 sharper, that is, just between a quarter and tone, or thereabouts. This supposition seems to rec all the statements best. If we took Smart's a pitch, used in 1843, of A 433, it would beat too str with Handel's A 422.5 (except in very hot we indeed, upwards of  $80^{\circ} \text{F.}$ ) for any reasonable suppose they were identical. This second pitch also give as an original, about A 454.2 (see p. col. 1), which was not likely to have been any used by B. Schmidt (see table on p. 331, col. 1 the discussion under A 474.1). "The organ re new sound boards from the late Mr. Robson,

at is, the quarter-tones were then abolished, any new stops by Schulze and Robson. It was then raised by Robson," to its state A 441.2, which, by the above discussion, is probably very nearly its original pitch, "but identically for the stops made, and finished away by Schulze, as may be seen on examining a now in use." The pipes, when measured, are in precise equal temperament, which would 441.3, EB flat 470.7, EB 498.7, EC 528.4, or EB 499.3, EB flat 471.3, EA 444.8.

As regards St. Paul's organ, which Mr. Clarke said to be in unison with Handel's fork (p. 319, A 427.6), Messrs. Forster and Andrews say that, it was altered in pitch by the late J. C. Bishop, but made flatter some years previously to 1839, as then stated, by Allman and Nutt. Every pipe in the organ had been pieced, even to the flue pipes, but at that date there had been no addition of pipes. This makes it probable that St. Paul's, the Temple, and Hampton Court, were all at the same pitch, about A 442, MC 529.

*Belgian Army Military Instrument Pitch.*—App. p. 403. Omit the passage, l. 15, "Hence, as f," . . . to l. 20, "more probable," which was added before Dr. Koenig's correction of his own as known, and insert:—

Large copies I measured were A 451.7, at 59° F. must have measured by his old standard, so being one in the 800 (see above, No. 10), was 451.56 at 59° F., which agrees so closely with the statement, that the difference may arise from error in copying by ear, or else Koenig may have set himself with giving the nearest number of single vibrations, and thus called 8V 902.25 which would account for the difference.

At the end of this paragraph, App. 10, add, as in my reprint:—

Mr. Mahillon also says that the so-called fork Belgian Guides (see p. 330, col. 1, A 455.5), proposing, never existed. The pitch of A was really given by M. Bender on a small clarinet, on he played, and such a pitch is, of course, very low. M. C. Mahillon, however, possessed a fork from it, which was at lowest A 456.

*Belgian Tynedock Organ.* Page 403, App. 11, Omit "For a similar pitch" to the end of the paragraph.

There are all the additions and corrections that I have found it necessary to make. In conclusion, I express my thanks to the Society of Arts for giving me a silver medal for my "History of Pitch."

ALEXANDER J. ELLIS.

5-road, Kensington, W., 29 Dec 1880.

## OBITUARY.

*Chemist, F.R.S.*—John Stenhouse, LL.D., the chemist, died on the 31st December, 1880, in his second year of his age. He was a native of Glasgow, in which city he lived for many years. On account of the failure of the Western Bank of Scotland, which deprived him of his fortune, he came to London and was appointed Lecturer on Chemistry at St. George's Hospital. This appointment he was obliged to resign in 1867, on account of a severe attack of paralysis, which disabled him. He succeeded Dr. St. George as non-resident assayer to the Mint in 1865, and this office was abolished by the Chancellor of the Exchequer (Mr. Lowe). Dr. Stenhouse was awarded a Royal medal by the Council of the Royal

Society in 1871, for his researches on the lichens, and their proximate constituents and derivatives, including erythrite, and for his researches on the action of charcoal in purifying the air." In 1854 he read a paper before the Society of Arts, "On the Deodorising and Disinfecting Properties of Charcoal, with the Description of a Charcoal Respirator for Purifying the Air by Filtration," and in 1861 he was elected a member. Besides the charcoal respirator, he was the inventor of a charcoal ventilator for sewers, and a process for rendering fabrics waterproof by means of paraffin. Although his bodily powers were much enfeebled, he continued his scientific researches up to the last.

## GENERAL NOTES.

*The Electric Light at the Liverpool Docks.*—It was resolved at a recent meeting of the Mersey Docks and Harbour Board, that the electric light should be adopted at a portion of the new dock system at the north end of the city, the estimated cost being £2,000. This is to be an experiment, and upon the result will depend the extension of the light over the docks generally.

*Society of Telegraph Engineers.*—The library of the Society (which includes the Ronalds Library) is now open daily, between the hours of 11 a.m. and 8 p.m., except on Thursdays and Saturdays, when it closes at 2 p.m. The privilege of using the library is extended to members of all scientific bodies, and to the public generally, on application to the Librarian, at the Society's house, 4, Broad Sanctuary, Westminster.

*International Woollen Exhibition.*—At the request of several foreign States, the time for receiving applications for space at this Exhibition, which will be held this year at the Crystal Palace, has been extended to the 1st April. The Government of New Zealand has asked for 1,500 square feet of space, and articles that have been shown at the Sydney and Melbourne Exhibitions will be sent from New South Wales and Victoria. The applications to exhibit machinery in motion are stated to be so numerous that it is expected that a large portion of the main floor of the building will be assigned for this purpose.

*International Exhibition of Hygiene.*—At a meeting of the Committee of the Parkes Museum of Hygiene, it was resolved "That her Majesty's Commissioners of 1861, having expressed to the committee of the Parkes Museum of Hygiene their willingness to provide space at South Kensington for an Exhibition of Sanitary Appliances and the Industries Connected with Medicine on the occasion of the Industrial Medical Congress in 1881, it is desirable that the committee should organise such an Exhibition, provided that a sufficient guarantee fund be obtained." Those desirous of assisting the committee are requested to send their names to the treasurer of the Museum, Professor Berkeley Hill.

*Moscow Industrial Art Exhibition.*—The fifteenth Exhibition of manufactures and artistic productions of the Russian Empire will be held at Moscow from the 15th May to the 15th September, 1881. The articles exhibited will be divided into 83 classes, arranged under 11 groups. Group 1.—*Works of Art* will consist of oil paintings, sculpture, architecture, engravings, art metal work, and water colours. Group 2.—*Scientific Educational Subjects*, including musical instruments, typography, lithography, photography, &c. Group 3.—*Agricultural Productions*. Group 4.—*Mining Productions and Salt Industry*. Group 5.—*Manufactures from Fibrous Substances*. Group 6.—*Manufactures from Metal*. Group 7.—*Productions Manufactured at Works*, as sugar, starch, tobacco, candles, soap, oils, leather, india-rubber, paper, glass, chemicals, &c. Group 8.—*Industrial Manufactures*, bookbinding, upholstery, clothing, &c. Group 9.—*Machines, Apparatus, Materials of Construction, and Workmanship*. Group 10.—*Horticulture and Gardening*. Group 11.—*Domestic Animals*.

## MEETINGS OF THE SOCIETY.

## ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

JANUARY 12.—“A Sanitary Protection Association for London.” By W. FLEEMING JENKIN, F.R.S. On this evening Professor HUXLEY, LL.D., F.R.S., will preside.

JANUARY 19.—“Causes of Success and Failure in Modern Gold Mining.” By A. G. LOCK.

JANUARY 26.—“Five Years' Experience of the Working of the Trade Marks' Registration Act.” By EDMUND JOHNSON.

FEBRUARY 2.—“Trade Prospects.” By STEPHEN BOURNE.

FEBRUARY 9.—“The Present Condition of the Art of Wood-carving in England.” By J. HUNGERFORD POLLEN.

FEBRUARY 16.—“The Participation of Labour in the Profits of Enterprise.” By SEDLEY TAYLOR, M.A., late Fellow of Trinity College, Cambridge.

FEBRUARY 23.—“Recent Advances in Electric Lighting.” By W. H. PREECE, Pres. Soc. Tel. Eng.

MARCH 2.—“Flashing Signals for Lighthouses.” By Sir WILLIAM THOMSON, LL.D., F.R.S.

MARCH 9.—“Improvements in the Treatment of Esparto for the Manufacture of Paper.” By WILLIAM ARNOT, F.C.S.

MARCH 16.—“The Manufacture of Aerated Waters.” By T. P. BRUCE WARREN.

Dates not yet fixed:—

“Buying and Selling; its Nature and its Tools.” By Prof. BONAMY PRICE. On this evening Lord ALFRED S. CHURCHILL will preside.

“The Discrimination and Artistic Use of Precious Stones.” By Prof. A. H. CHURCH, F.C.S.

“The Compound Air Engine.” By Col. F. BEAUMONT, R.E.

“The Increasing Danger to Life and Property from Explosions.” By CORNELIUS WALFORD.

## FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

FEBRUARY 1.—“The Industrial Products of South Africa.” By the Right Honourable Sir HENRY BARTLE FRERE, Bart., G.C.B., G.C.S.I., D.C.L., LL.D., F.R.G.S., &c.

FEBRUARY 22.—“The Languages of South Africa.” By ROBERT N. CUST.

MARCH 15.—“The Loo Choo Islands.” By Consul JOHN A. GUBBINS.

APRIL 5.—“Trade Relations between Great Britain and her Dependencies.” By WILLIAM WESTGAERTH.

## APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

JANUARY 27.—“A New Mechanical Furnace, and a Continuous System of Manufacturing Sulphate of Soda.” By JAMES MACTEAR. J. C. STEVENSON, M.P., will preside.

FEBRUARY 24.—“Deep Sea Investigation, and the Apparatus used in it.” By J. G. BUCHANAN, F.R.S.E., F.C.S.

MARCH 24.—“The Future Development of Electrical Appliances.” By Prof. JOHN PERRY.

## INDIAN SECTION.

Friday evenings, at eight o'clock:—

JANUARY 21.—“Forest Conservancy in India.” By Sir RICHARD TEMPLE, Bart., G.C.S.I.

FEBRUARY 11.—“The Gold Fields of India.” HYDE CLARKE.

MARCH 4.—“The Results of British Rule in India.” By J. M. MACLEAN.

MARCH 25.—“The Tenure and Cultivation of in India.” By Sir GEORGE CAMPBELL, K.C.S.I.

MAY 13.—“Burmah.” By General Sir A. PHAYRE, G.C.M.G., K.C.S.I., C.B.

## CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Second Course will be on “Watchmaking” by EDWARD RIGG, M.A. Three Lectures.

February 7, 14, 21.

The Third Course will be on “The Scientific Principles involved in Electric Lighting,” by W. G. ADAMS, F.R.S. Four Lectures.

March 7, 14, 21, 28.

The Fourth Course will be on “The Art of making,” by ALAN S. COLE. Three Lectures.

April 25; May 2, 9.

The Fifth Course will be on “Colour Blending and its Influence upon Various Industries,” by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

May 16, 23, 30.

## MEETINGS FOR THE ENSUING WEEK

MONDAY, JAN. 10.—Institute of Surveyors, 12, Great George-street, S.W., 8 p.m. Resumed Discussion on Mr. paper, “The Land Question in 1880.”  
Medical, 11, Chandos-street, W., 8½ p.m.  
London Institution, Finsbury-circus, E.C., 5 p.m.  
Harrison, “The French Revolution and the Histories of it.”

TUESDAY, JAN. 11.—Medical and Chirurgical, 53, Berners Oxford-street, W., 8½ p.m.  
Civil Engineers, 25, Great George-street, W., S.W., 8 p.m. Inaugural Address by the Pres. Abernethy, and Monthly Ballot for Members.  
Photographic, 5A, Pall-mall East, S.W., 8 p.m.  
Viles, “The Optical Lantern.”  
Anthropological Institute, 4, St. Martin's-place, 8 p.m.  
Royal Horticultural, South Kensington, S.W., 1

WEDNESDAY, JAN. 12.—SOCIETY OF ARTS, John Adelphi, W.C., 8 p.m. Prof. Fleeming Jen Sanitary Protection Association for London.  
Graphic, University College, W.C., 8 p.m.  
Microscopical, King's College, W.C., 8 p.m. 1. Martin Duncan, “Three Microspongiadae to the Hexactinellids from the Deep Sea.”  
Shadbolt, “The Aperture Question.” 3. Prof. “The True Conditions of Stereoscopic and Pseudo Effect in Microscopical Vision.” 4. Mr. A. D. “A Species of Acarus believed to be Unrecorded.”  
Royal Literary Fund, 10, John-street, Adelphi, 3 p.m.  
Obstetrical, 53, Berners-street, Oxford-street, 1

THURSDAY, JAN. 13.—Royal, Burlington-house, W., 4½ p.m.  
Antiquaries, Burlington-house, W., 8½ p.m.  
London Institution, Finsbury-circus, E.C., 7 p.m.  
Henry Blackburn, “The Art of Popular Illustrations.”  
Inventors' Institute, 4, St. Martin's-place, W.  
Royal Society Club, Willis's-rooms, St. James 6 p.m.  
Mathematical, 22, Albemarle-street, W., 8 p.m.  
A. J. Ellis, “An Apparently Paradoxical Result in the Circle, Parabola, and Hyperbola.” 2. I. Terry, “A Proof of the Differential Equation satisfied by the Hypergeometric System.”  
R. Westropp Roberts, “The Periodicity of Elliptic Integrals of the First-class.” 4. I. Roberts, “The Tangents drawn from a Point to a Nodal Cubic.”

FRIDAY, JAN. 14.—Astronomical, Burlington-house, W., Philological, University College, W.C., 8 p.m.  
Quekett Microscopical Club, University College, 8 p.m.  
Clinical, 53, Berners-street, W., 8½ p.m. Annual

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,469. Vol. XXIX.

FRIDAY, JANUARY 14, 1881.

*All communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## PROCEEDINGS OF THE SOCIETY.

## MUSICAL EXAMINATIONS.

The Society of Arts' practical examination in vocal and instrumental music was held, as announced, on Monday and Tuesday, January 10th and 11th, by John Hullah, LL.D., assisted by W. Barrett, Mus. Bac. Seventy-two candidates were examined. Dr. Hullah has promised a report, which will appear shortly.

The next practical examination will be held during the week commencing 11th July, 1881. Information as to these examinations can be obtained from the Secretary.

## SIXTH ORDINARY MEETING.

Wednesday, January 12th, 1881; Professor THOMAS H. HUXLEY, LL.D., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Amessey, Antonius, 87, Seymour-street, Hyde-pk., W.  
Ball, John Ball, F.R.G.S., Carisbrooke-lodge, St. John's-road East, Putney.  
Carpmeal, Edward, Streatham-hill.  
Clark, Mateo, 88, Richmond-road, Bayswater, W.  
Crowth, Richard William, 18, Cookspur-street, S.W.  
De Villiers, Peter, M.D., Ellora-villa, Silverhill, St. Leonards-on-Sea.  
Fell, John Barraclough, The Warren, Torrington, Devon.  
Folkard, Henry Tennyson, Wigan.  
Gostling, William Kennedy, 8, Gloucester-square, Hyde-park, W.  
Herring, John Barnwell, The Grove, Esher, Surrey.  
Hill, Robert Martin, 117, Leadenhall-street, E.C.  
Klein, Adolphe Louis, Burton-in-Lonsdale, Yorkshire.  
Robinson, Robert Alleyne, South-lodge, Cockermouth, Cumberland.  
Sawyer, William Phillips, Drapers'-hall, Throgmorton-street, E.C.  
Snee, Arthur R., Penrhyn-lodge, Woodberry-down, N.  
Standfield, John, 6, Westminster-chambers, S.W., and 44, Lillieshall-road, Clapham, S.W.  
Surtees, Colonel Charles F., Chalcott-house, Long Ditton, Surrey.  
Tapsen, John, M.D., 12, St. German's-place, Blackheath.  
Theobald, John Peter, The Chestnut-grove, Kingston-on-Thames.  
Thompson, John, Mayor of Peterborough.  
Tumlin, Illius Augustus, 17, Parliament-street, S.W.  
Waterlow, Herbert Jameson, 1, The Avenue, Brondesbury, N.W.  
Wiggins, Rev. William, Spring-vale, Tonge, Middleton, Lancashire.

Wilson, Rev. Charles Thomas, Chapmore-end, Ware.  
Wood, James, 26, Cross-street, Ryde, Isle of Wight.  
Wright, E. G., 330, Commercial-road, Landport.

The following candidates were balloted for, and duly elected members of the Society:—

Aird, David Alfred, 2, Sussex-gardens, Hyde-park, W.  
Angus, Joseph, The Hermitage, Langley-lane, South Lambeth, S.W.  
Clements, Hugh, 5, Park-terrace, Peckham, S.E.  
Foster, Thos. Nelson, Allt Dinas, Bayshill, Cheltenham.  
Morton, Joseph, 39, Cheapside, E.C.  
Obach, Dr. E., 17, Charlton-villas, Church-lane, Old Charlton, S.E.  
Riddiford, George Francis, Barnwood-lodge, Gloucester.  
Ridpath, J. Lionel, 12, West Kensington-gardens, W.  
Snelgrove, Horatio Richard, The Grove, Clapham-common, S.W.  
Sykes, Fred. W., Gosport Mills, Huddersfield.  
Traill, James Christie (of Rattar, N.B.), Castlehill, Thurso, Caithness.  
Vogel, Sir Julius, K.C.M.G., 135, Cromwell-road, South Kensington, S.W.  
Ward, Frederick Peterson, 46, Hamilton-terrace, St. John's-wood, N.W.  
Wright, John Brooks, 96, Buchanan-street, Glasgow.  
Young, Charles E., 71, Clapham-road, S.W.  
Young, Sir Charles Lawrence, Bart., 5, Ashburn-place, Cromwell-road, S.W.  
Young, George, 7, The Terrace, Ryde, Isle of Wight, and 43, Dover-street, Piccadilly, W.

The paper read was on—

## A SANITARY PROTECTION ASSOCIATION FOR LONDON.

By Prof. Fleeming Jenkin, F.R.S.

Many present may, in the first place, be inclined to ask the question, What is a Sanitary Protection Association? A short account of how the first association of this kind came into existence may, perhaps, convey a clearer idea of the objects aimed at than any mere enumeration of those objects, such as might be given in a prospectus. In the winter of 1877-78, the writer was asked to deliver two lectures on Sanitation before the Philosophical Institution in Edinburgh, and he gladly accepted the duty, believing that there would be no great difficulty in giving simple explanations on the subject, and in laying down rules so simple that each householder might easily apply those rules to his own case, and so render himself secure against the chief dangers arising from bad drainage, bad water supply, and bad ventilation. There is, practically, no serious difference among experts as to the principles to be observed, or, perhaps, it might be more correctly said that there exists a practical agreement as to the main principles and chief points of practice, and that the differences as to practice relate only to minor details. Undoubtedly, a warm discussion often arises, even now, as to the relative merits of various forms of sanitary apparatus, but this discussion is often hottest when the several forms are all good; and an impartial hearer might observe that all speeches appealed to common, well-proved principles, by which the several appliances were judged. The writer holds the opinion that, while niceties of construction cannot be too warmly debated among manufacturers and engineers, they are, nevertheless, of small importance in comparison with a few very simple conditions, the observance of which

will practically ensure that a house is in good sanitary order. Very briefly, these main conditions may be stated as follows:—

1. The liquid refuse from the house must have a free passage to the town sewer.
2. The air from the town sewer must not have a free passage into the house drains.
3. No air or gas from the drainage channels of the house must enter the house.
4. No water or liquids must leak from those channels into the ground under the house.
5. The drinking water must be supplied and stored in such a manner as to run no risk of contamination.
6. The air of the dwelling rooms must be supplied from without uncontaminated.

These points could easily be made clear to an audience, but then came the difficulty of explaining how the various pipes and traps throughout the house ought to be arranged, with a view to securing these conditions; then it was further necessary to explain the modes of practically testing whether pipes were open that should be open, passages closed which should be closed; whether the various channels, with their joints, were so made as to be and remain gas-tight and water-tight. By the time these details, with the necessary diagrams and experiments had been arranged for the lecture, the matter no longer appeared thoroughly simple; indeed, the diagram showing the pipes of a very small house, although made purposely simple for the purpose of explanation, presented an appearance so complex that, after the lecture had been given, one of the audience was heard to remark jocularly, that he had not room in his whole house for such a number of pipes as that. The anecdote tells against the lecturer, for it shows that he had utterly failed to explain his meaning to his hearers; but it also serves to illustrate an undoubted fact, that most householders are quite unaware of the great number and complexity of the channels which penetrate their houses, and yet each one of those channels may become a source of danger.

By the time that the preparations for the lecture were complete, the writer had arrived at the discouraging conclusion that its delivery would be practically useless—that it would add little or nothing to the knowledge of experts, and that the ordinary householder could not be expected so completely to master the subject as might warrant him in trusting to his own judgment when applying the principles. What conclusion, then, was to be drawn? Apparently, only the very lame one, that each occupier ought to call in professional advice, to see, in the first instance, that proper arrangements had been made, and from time to time to inspect whether they continued in working order. But what advice could the public obtain? The plumber and builder were interested parties, and in many cases were insufficiently educated to give sound advice. The engineer, if consulted, must be a man of standing, and would charge a fee such as would be prohibitory in the case of houses belonging to persons of moderate means. The public authorities were in Edinburgh, the Medical Officer of Health and Burgh Engineer. These might be consulted in any case where a nuisance was detected, or even sus-

pected; but it formed no part of their duty to give detailed professional reports as to the arrangement and condition of private houses, in which there was no special reason to suppose that serious defects existed. These officials would have had good reason to complain if the writer had induced 500 or 1,000 householders at once to apply for plans and diagrams of their drainage and water supply, accompanied by detailed reports and specifications of changes necessary or desirable, and to be followed by a subsequent periodical and practical inspection of these works. It was, moreover, obvious that the householders would not be induced to make this application. The lecturer, then, was in the position of having to tell his hearers that the water-carriage system, as it is called, had introduced into their houses a very serious danger; that the complexity of pipes and traps was such that this danger could not be guarded against without professional advice and continual inspection, and yet that no practical means existed, by which men of moderate means could obtain trustworthy professional advice. This conclusion was so unsatisfactory, that he was led to consider whether no plan could be devised for giving sound professional advice and inspection in return for small fees. The idea then occurred to him that the principle first applied by the late Sir William Fairbairn to the inspection of steam boilers, was also applicable to the inspection of houses. An association might be formed, which should employ an engineer or engineers of their own. Each engineer so employed, could inspect and report on a large number of houses annually, and if employed exclusively on this work, he would rapidly acquire great skill and experience. The writer knew that large numbers of well educated young men, who passed through his class in the University and through their practical apprenticeship, would be glad to give their time for about £150 per annum. If these men were to inspect houses and report upon them under the eye of a consulting engineer of standing, the householder would have a guarantee that the principles on which the reports were drawn up, and the inspections made, were such as commanded the assent of the heads of the profession, and, nevertheless, the fee of the consulting engineer who gave this guarantee need not be more, for, say, 100 houses, than he would have to charge for a single house if he were called in for that one special case.

An estimate showed that, including the payment of a secretary, rent for offices, and sundry minor expenses, the proposed benefits could be given in Edinburgh for a subscription of £1 1s. per annum, an estimate which has since been justified by an experience of three years.

The idea was explained privately to a few friends, and met with so much favour that draft rules were passed, and the following circular issued:—

#### SANITARY PROTECTION ASSOCIATION.

Edinburgh, 21st January, 1878.

SIR,—I have the honour to enclose for your consideration the draft of a prospectus of this association, which is in course of being formed. Your special attention is requested to the following points:—

1. The association is a society for the benefit of its members and the community, and cannot, under its articles, be used for any purposes of profit.
2. The privileges of members include the annual in-

pection of their premises, as well as a preliminary report on their condition, accompanied by an estimate of the cost of any alterations recommended.

3. Even when drains and other sanitary appliances have been put in thorough order, it is impossible to secure that they shall remain in that state without the skilled inspection, from time to time, which it is one main object of the association to provide.

4. No obligation will rest on members to carry out the recommendations made by officers of the association, whose one duty will be to give skilled advice when this is desired by the members.

5. The officers of the association will have no interest in recommending any outlay.

6. The association may (under Rule 5) be of great service to the poorer members of the community.

The following gentlemen have approved of the rules of the association, and consented to act as a provisional committee of management until 500 names shall have been enrolled. Upon this the first general meeting will be held, and a permanent council appointed:—

*Provisional Committee.*—The Right Hon. the Earl of Rosebery; the Right Hon. Lord Moncreiff, of Tulliebole, Lord Justice-Clerk; the Right Hon. the Lord Advocate, M.P.; Sir Robert Christison, Bart., D.C.L.; the Hon. Lord Shand; the Hon. Lord Cruggill; the Hon. Lord Rutherford Clark, LL.D.; James Cowan, M.P.; the President Royal College of Physicians; the President Royal College of Surgeons; the Right Rev. Bishop Cotterill, D.D., &c.

Should you approve of the object of the association, and wish to become a member, you are requested to sign the enclosed form, and send it to the temporary office, 35 North Frederick-street, addressed to the Interim Secretary, Captain Charles Douglas [of No. 2, Rutland-square].

I have the honour to be,

Your most obedient servant,

FLEEMING JENKIN.

The rules of the association were revised by the provisional committee, consisting of leading citizens in Edinburgh, and the writer was able, at his lecture before the Philosophical Institution, just three years ago, to announce that the association for Edinburgh was constituted. Since that time, and under those rules, the association has worked with perfect smoothness and success. It has given satisfaction to its members; it has paid its way; it has spread widely through Scotland, and its action has in no instance given rise to any challenge or ill-feeling. Under these circumstances, the Council of the Society of Arts accepted the present paper, by which the announcement is made that a similar association is now founded in London.

The rules of the London Association are appended. They differ little from those of the Edinburgh Association, and such differences as exist have been adjusted by the London Council. The following abstract will probably be sufficient to explain what the association undertakes to do. The objects are defined as follows:—

1. To provide members, at moderate cost, with such advice and supervision as shall ensure the proper sanitary condition of their own dwellings.

2. To enable members to procure practical advice, on moderate terms, as to the best means of remedying defects in houses of the poorer class in which they are interested.

The entrance fee, which entitles to all privileges of membership for twelve months, is £2 2s. for houses situated within five miles of Charing-cross and rated below £400 per annum. The subsequent

annual subscription for the same houses will be £1 1s. Special rates for larger houses can be ascertained from the Secretary.

The following are the privileges of the members:—

1. A report by the engineer of the association on the sanitary condition of one dwelling, with a sketch diagram of pipes, and specific recommendations, if necessary, as to the improvement of drainage, water supply, and ventilation.

2. The inspection of any alterations in the sanitary fittings which may be carried out by the advice, or with the approval, of the officers of the association.

3. An annual inspection of premises by the engineer, with a report as to their sanitary condition.

4. Occasional supplementary inspection and advice concerning the dwelling or property in respect of which he is a subscriber, whenever this advice may be desired. The fee for such occasional advice will be fixed from time to time by the Council.

5. Reports by the officers of the association as to the sanitary condition of any dwellings or properties designated by any member, or on any plans for proposed buildings, on payment of a fee to be fixed by the Council from time to time, with special relation to the rent, or estimated rent, of the premises.

6. A vote in the election of the council, who manage the affairs of the association.

Any member is free to leave the association at any time; non-payment of the annual subscription will suffice to cause the removal of his name from the roll. The association has no share capital and no profits. The Board of Trade have signified their willingness to license the Edinburgh Association as one of public utility under the Act of 1867, Victoria 30—31, c. 131, and the Board will, no doubt, be prepared to grant an equal privilege to the London Association.

The Council of the association will, by its articles, be unpaid; the officers have no interest in any outlay or patent.

The first council will be constituted as follows:—President—Prof. T. H. Huxley, LL.D., F.R.S., &c. Ordinary Councillors—J. S. Bristowe, M.D., President of the Society of Medical Officers of Health; Sir Wm. Gull, Bart., M.D., D.C.L.; Rev. Harry Jones, rector of St. George's-in-the-East; Hugh Leonard, late Engineer-in-Chief, Bengal Presidency; F. Clifford de Lousada, retired commander R.N.; Sir W. Tyrone Power, K.C.B.; E. C. Robins, F.R.I.B.A.; Professor J. S. Burdon Sanderson, M.D., LL.D., F.R.S.; Professor Alex. W. Williamson, F.R.S., &c. Honorary Standing Counsel—Alfred Wills, Q.C. Honorary Treasurer—T. Holmes, M.A. Cantab., Surgeon and Lecturer on Surgery to St. George's Hospital.

The following will be the first paid officers of this association, holding office at the will and pleasure of the Council:—Consulting Engineers—Fleeming Jenkin, F.R.S., M.I.C.E., Professor of Engineering in the University of Edinburgh and Consulting Engineer to the Edinburgh Sanitary Protection Association; and H. C. Forde, M.I.C.E. Resident Engineer—W. K. Burton. Secretary—Cosmo Innes, M.I.C.E., 6, John-street, Adelphi.

A short account will now be given of the

manner in which the system is practically worked. A householder or tenant who thinks of joining the association will write to the secretary, Mr. Cosmo Innes, at 6, John-street, Adelphi. In his letter he will state the nature of the premises in respect of which he wishes to subscribe. He will mention the rateable value or actual rent, and the situation of the house. If the situation be within five miles of Charing-cross, and the rateable value of the house under £400, he will know that the terms of the subscription are £2 2s. for the first year, and £1 1s. for each subsequent year. He may either ask the secretary for further information, or he may at once signify his intention of joining the association as a member, and enclose a cheque for £2 2s. He may, if he pleases, call and obtain verbal information from the secretary. When a member joins he incurs no liability, except for the first two guineas. He may or may not pay any subsequent annual subscription; but it is hoped that most of the members who join will remain members of the association, since otherwise they will not receive the full benefit of the scheme. As soon after the member has joined as circumstances allow, the secretary will write to the member, and inquire when it will be most convenient to him to have his house inspected. When the inspection is arranged, the member will be asked to let his plumber meet the inspecting engineer, and also to have the ground opened up in such a manner as to expose the main drain of the house at some point between the house and the town sewer. If the extra expense which this entails is objected to, the inspection cannot be thorough, but may still be useful. The sums paid for opening up the ground do not pass through the hands of the association. Unless some grave defect is discovered in the drain under the house, the opening up of the drain, being done outside the house, need cause no inconvenience to the inmates. The engineer inspects the condition of the main drain, and, assisted by the plumber, takes notes of every pipe, trap, and sanitary convenience in the house; he makes inquiries as to smells and ventilation; he examines all cisterns and arrangements for water supply. When this is practicable, he tests the condition of the pipes by pouring paraffin, or some other volatile strong smelling substance, into the drainage system from the roof. If the smell can anywhere be detected inside the house, a flaw is thereby indicated; this is then laid bare. As soon after the inspection as may be, the member receives a detailed report, describing the condition of his house, accompanied by a sketch diagram showing every pipe and trap; recommendations for improvements are made when necessary, as is usually the case, and some rough estimate can be given of the probable cost of those improvements when this is desired. The improvements recommended are those only which are shown by every-day experience to be necessary. The wishes of the occupier are taken into account, and the more important are distinguished from the less important alterations. The recommendations made are sufficiently specific to enable the member to obtain an estimate from his plumber or builder of the cost of carrying them out. The cost is often considerable, but the member may feel assured that the association has no interest whatever in recommending any expenditure.

The interest of its officers is in the other direction. The less that is done to a house, the less trouble they will have. The less that is done the more popular the association will be. It is, however, only fair to state, that, in the great majority of cases, subscription to the association leads to an outlay in the first year largely in excess of the annual payment. This outlay does not pass through the hands of the association. If the member decides to carry out the recommendations made, or any of them, and gives the secretary notice of his intention, arrangements will be made to inspect the work when completed, or nearly completed. This inspection of the plumbing and other work is one of the most valuable privileges which the member obtains by joining the association. When the alterations have been satisfactorily completed, the member can, on application, obtain a certificate as to the sanitary condition of his premises. This certificate will be of great value to hotels, lodging-houses, and schools. The recommendations made to members invariably include such arrangements as will preclude the necessity for ever again incurring expense in opening up the drain for inspection.

At this point the writer feels that probably all present believe more has been promised than can possibly be performed for the money. This feeling will not be least strong among those best qualified to give an opinion. The writer can, however, speak with the authority of complete experience. It has been shown that these services can be rendered in a thorough and efficient manner, by one resident engineer, for 430 houses or even 500, in one year. The reports, sketch diagrams, and letters in Edinburgh are open to the inspection of all whom it may concern. During three years there has not been one case of complaint that the houses were not thoroughly examined, or that the reports were not sufficiently detailed. At the annual meeting, member after member has risen to express his sense of the thoroughness of the work, and Scotsmen are not easily deluded or even satisfied on this point. At the outset the writer could only plead his own conviction that the work could be done. He is now able to say that, in 1200 cases, it has been done.

The second inspection is a much simpler matter; when the guinea for the second year has been paid, the resident engineer visits the premises, assures himself, by ocular inspection, that there is a free outfall of sewage; paraffin or its equivalent is again poured into the drainage system, and a thorough search made for dry traps, broken joints, or worn-out lead. If the pipe under the house has been laid afresh, in accordance with the association's specification, it can, if necessary, be tested, to ascertain whether it remains water-tight. Inquiries are made as to any alterations which may have been made since the last visit. The condition of the cisterns is examined. The member then receives a second report, in accordance with the facts of the case. This practical and experimental inspection is repeated year after year; it entails no cost beyond the guinea, and no inconvenience. It renders the member practically secure that no imperfection in the drainage system can remain long undetected. More frequent inspections could be arranged for at cheap rates, in special cases, such as schools, where injuries are more likely to occur. The association, therefore, does

peal only, or even mainly, to those who have to believe that there are grave defects in houses. Its chief business begins when the is in good order. The householder is then position analogous to that of a manufacturer as bought a good steam boiler; he knows the apparatus is good, but liable to decay and cement; he employs the principle of co-operation to obtain skilled supervision to protect from the consequences of that decay or demerit. A less measure of inspection than is will not protect a house from the dangers able from the system of water carriage for e. re are other minor functions which the tion will fulfil.

will examine plans of projected buildings for acts and builders. This provision is taken tage of to a considerable extent in Edin-

association will also examine houses for us who propose to take them on lease, or for rds who propose to let houses.

member desires a report on the condition of other premises than his own, such as lodgings ied by the poor, a report will be made at ate rates, as a matter of special arrangement. ee reports are strictly private and confidential. ill be seen clearly that the association does ig which might not be undertaken by a single eudent engineer; where householders already y an engineer in a similar capacity, and are ed with his work, they will gain nothing by g the association. To the public in general, ouncil of the association, by the knowledge osition of its members, affords a guarantee he officers by whom the advice is given, and ection made, shall be skilled and honour- ersons. Moreover, it is the duty of the ong engineer to make sure that the principles uch advice is given are sound, and also to that the resident engineers carry out their in a zealous and thorough manner. The ry, also, can aid in watching over the resi- engineers, and in our present association he be specially qualified to do this, for Mr. is himself a member of the Institution of Engineers, and has had large experience of engineers' work. The writer will gladly r any questions as to points which may not, e have been made clear to the meeting.

ore concluding, it may be well to answer by ation some of the objections which were to the association when it was first pro- in the North, and which might possibly be ed here. Some people refused to give it untenance, on the ground that they did not e anyone knew anything about sanitation.

is no answer to this objection. Then the assertion that if any one knew anything these subjects it was the family plumber. y be admitted with satisfaction that some ers now really have the knowledge which ies them to give advice to their clients. It be expected that this will more and more to be the case; but the association will meet ants of those persons who have not complete ence in the plumber; indeed, even if all ers were thoroughly educated, and thoroughly orthy, it would still be desirable that,

like all other contractors, they should do their work under professional inspection. Even the late Thomas Brassey—and no name could be mentioned which commands greater respect—was in the habit of saying that it was better he, as contractor, should work under inspection. The interests of the tradesman are not those of his employer; the employer himself has not the technical knowledge which would enable him to control the plumber. The association steps in, and gives the necessary professional assistance. Here it may be remarked that at first the plumbers and builders in Edinburgh viewed the association with some suspicion, and in certain cases with dislike. These feelings have entirely disappeared. It was found that the association led to the execution of more work than would have been done without its suggestions, and that the impartial inspection of its officers was a positive benefit to those tradesmen who did good work.

To continue the list of objectors; a considerable number of persons admitted that the work was both necessary and possible, but asserted that the means provided for carrying it out were inadequate. The inspection would not be real or thorough; and that a sham inspection was actually worse than none. This last proposition must be granted at once. Fortunately, experience has shown that the fears expressed were groundless. If testimonials were wanted from members, they could be had by hundreds. As another proof, the very list of clients might be annexed; these include several of the leading engineers in Edinburgh, Messrs. E. Blyth, B. Blyth, H. Blyth, G. Cunningham Leslie, T. Stevenson, the Royal Bank, the Union Bank, British Linen Bank, the Incurable Hospital, Chalmers Hospital, the Sick Children's Hospital, the Maternity Hospitals, the School Boards, and many other public bodies. The writer is certain that no person acquainted with Edinburgh will state that the inspections, as now conducted, are shams. Perhaps the fear was grounded on a complete misconception. The association makes no pretence at putting badly-drained houses into good sanitary condition for one or two guineas. The improvements must invariably cost a considerable sum—twenty, forty, fifty, even a hundred guineas; in some cases, twice that amount.

The next class of objectors said the association would do too little—that it should not merely give advice, and inspect plumbers, but should itself do the work. It is not denied that an opening exists for plumbing establishments in which the principle of co-operation might be taken advantage of; but this is not, and cannot be, a branch of the present association. To execute plumbing and building, capital is required. If it undertook work, the association would become an ordinary trading company, with the risks and profits incidental to trade. It would no longer be an association of public utility, giving disinterested advice, but simply one more shop competing with other shops.

The next opponent admitted that the objects aimed at were of great importance—of such importance, indeed, that, in his opinion, they ought to be carried out by public authority, and not by a mere private association. So far the writer agrees

with what was said, but the conclusion is surely false, that we ought not to do anything for ourselves which Government might possibly do for us. A considerable number of persons declined to join the association because they thought it weakened the claim of the community to have that done by compulsion and taxation which the association carried out by the voluntary principle. The writer respects the heroism of those who die as martyrs, and let their children die, in unhealthy houses, rather than have these made healthy by a means which they deem impolitic—but he thinks their reasoning unsound.

In this country, custom precedes law, and no better laws are made than those which recognise and extend good customs. If we can show that, at small expense, a thorough inspection can be carried out in the houses of the well-to-do, that this inspection is needed, welcome, and effectual, we shall greatly strengthen the hands of those who would extend that inspection down to the poorest hovel in the town, an object in which they have the heartiest sympathy of the writer. This association is probably only one step towards a general compulsory inspection. When this is established, the association may either cease to exist as no longer needed, or continue to exist, as supplying a better and fuller inspection than that provided by law. Meanwhile, no one need hesitate to join, from any fear that, by so doing, they would weaken the case of those who would forward improved sanitary legal measures.

Next in our list of opponents came those who said the law already provided all that was required—that, in Edinburgh, the medical officer of health and burgh engineer, and, in London, the medical officer of health, the inspector of nuisances, the local surveyor, and the surveyor appointed by the Metropolitan Board of Works already gave, or could give, gratis all that the association promised to give for a guinea. It is quite certain that the ratepayers have privileges of which they are largely ignorant, and of which they very seldom avail themselves. It is also certain that, in most cases, these public officials are obliging and zealous in giving their services when asked to do so; but it is equally certain that neither in Edinburgh nor in London is such a systematic inspection as the association offers carried out by law. If the public could and did insist upon such an inspection, the public staff would have to be increased ten or twenty fold. The writer will not be so bold as to give the smallest opinion as to what the rights of the ratepayer may be under the Metropolitan Local Management Acts, but it is notorious that the inspection which the association offers does not at present exist.

Next in the list of antagonists came those who looked on the association as a body inflicting a slur of some kind on the public authorities, or as established to supply some defect in their action—even as a disgrace to the town itself; for they urged, if the town had good sewers, your association would be of no use. Perhaps the best answer to those who agree with these gentlemen is, that the chief public sanitary authority, the convener of the Public Health Committee, is himself on our council in Edinburgh, and that the President of the Society of Medical Officers of Health is on the council of our society in London. Our work does

not clash with that of the public authorities; we begin where they leave off; inside houses which, unless some nuisance is reported, they have, probably, no power to enter. If sewers were all as perfect as sewers can be, the need of annual inspection would be diminished, but would not be ended. Bad sanitary fittings in a house may render nugatory all attempts to isolate cases of infectious illness occurring there, and this will remain true when every town sewer is perfect.

No one came forward in Edinburgh to say that the association was competing unfairly with professional men as sanitary advisers. This has been said in London, but the grounds of the accusation are not clear. The resident engineer is paid at the rate common for men of his standing. The consulting engineer receives a fee which, having regard to the call on his time, is remunerative.

All these objections experience has shown to be of no value, but there remains one objection which will always be serious. Persons shrink from becoming members because they fear that by enrolling they will be led to expend a considerable sum of money in sanitary improvements. "I do not mind the two guineas," they say, "but I shrink naturally from the fifty guineas which this may entail." The objection is valid, but yet it sounds strange when it is urged by a person who says, "I know my house is in very bad order; it was built long ago; rats abound; smells pervade, and we are much troubled by sore throats." What expenditure of money is justifiable if not that which tends to secure good health? No doubt the hesitation is partly due to a doubt whether the sanitary engineer really knows anything at all about the matter. The association does its best to remove that doubt; the reports explain what is wrong, why it is wrong, and what will put it right. The member is left to his own common sense as a guide whether he will follow the recommendations made. It is a matter of no pecuniary interest to his adviser whether the job is done or not, and that adviser is selected and watched by a council, consisting of men as well qualified for this purpose as can be found in London.

## APPENDIX.

The following documents, consisting of the provisional rules of the London Association, and the balance-sheet of the Edinburgh Association, are given here for the information of those who may wish to found associations of the kind in other parts of the kingdom or abroad:—

### I.—PROVISIONAL RULES.

#### OBJECTS OF THE ASSOCIATION.

The objects of this association are twofold:

1. To provide its members, at moderate cost, with such advice and supervision as shall ensure the proper sanitary condition of their own dwellings.

2. To enable members to procure practical advice, on moderate terms, as to the best means of remedying defects in houses of the poorer class in which they are interested.

No obligation will rest on members to carry out the recommendations made to them.

The association is not intended as a substitute for a municipal inspection, and will not conflict with the public authorities, but will supplement their action. Thus it is not proposed that the association should undertake the superintendence of houses while they are being built, or that it should in any way interfere with the public system of sewers.

## ADMISSION OF MEMBERS.

Persons become members on payment of an entrance fee, and continue to be members so long as they pay an annual subscription. The entrance fee and annual subscription are regulated by consideration of the annual value and situation of the dwellings in respect of which they are paid.

For ordinary dwellings within five miles of Charing-cross, and of a rateable value under £400 per annum, the entrance fee and subsequent annual subscription are fixed at £2 2s. and £1 1s. respectively for original members. The entrance fee, which may be paid at any time during the year, entitles the member to all the privileges of the association for twelve months from date of payment. The annual subscription is good for the following twelve months. For all other dwellings than those already named, the entrance fee and annual subscription will be determined by the council.

After the 1st of January, 1882, the council shall have power to increase or decrease the entrance fee and annual subscription for new members, but shall not have power to increase the annual subscription of members who have joined before that date.

## PRIVILEGES OF THE MEMBERS.

Each member will be entitled to the following privileges:—

1. A report by the engineer of the association on the sanitary condition of one dwelling, with a sketch diagram of pipes, and with specific recommendations, if necessary, as to the improvement of drainage, water supply, and ventilation. This report will be obtainable on his joining the association, or as soon thereafter as may be.

2. The inspection of any alterations in the sanitary fittings, which may be carried out by the advice, or with the approval, of the officers of the association.

3. An annual inspection of his premises by the engineer, with a report as to their sanitary condition.

**NOTE.**—No single inspection of any premises will secure permanent efficiency. Methodical inspection from time to time is absolutely necessary as a protection against inevitable decay, neglect, and accidental disturbance. Examples of failure where the design was good and the construction originally faultless are of daily occurrence, and are due to such causes as the gradual stopping of pipes and drains by kitchen grease and rubbish, the corrosion of metal pipes, the fracture of earthenware pipes, or the stopping of ventilation openings by dirt.

4. Occasional supplementary inspection and advice concerning the dwelling in respect of which he is a subscriber, whenever this advice may be desired, on payment of a small supplementary fee on each occasion that an officer of the association is called in. The fee for such occasional advice will be fixed from time to time by the council.

5. Reports by the officers of the association as to the sanitary condition of any dwellings designated by any member, or of any plans for proposed buildings, on payment of a fee to be fixed by the council from time to time, with special relation to the rent of the premises to be inspected.

**NOTE.**—Under this rule intending occupiers, architects, and builders will be able to avail themselves of the services of the association. This rule will also enable members to assist the poorer classes of the community. It is to be understood that no premises will be inspected unless the occupiers themselves assent to the inspection.

6. A vote in the election of the council who manage the affairs of the association. If one member subscribes in respect of several dwellings, he shall have a vote in respect of each.

**NOTE.**—The association will not publish any reports made to a member. The reports are to be considered confidential, and in using these reports each member must act on his own responsibility.

## MEETINGS.

A meeting of the association will be held annually in February, at which a council of at least ten members will be appointed, four of whom shall at any time be a quorum.

The council shall meet as often as from time to time may be found necessary for the disposal of business, and have power to call extraordinary meetings of the association when they think proper.

## OFFICERS OF THE ASSOCIATION.

**President and Council.**—The affairs of the association shall be managed by a council, who shall receive no remuneration, and who, with the exception of the first council, shall be elected from time to time by the members of the association from among their own body. The council shall, from their body, elect a president and a vice-president, whose business it shall be to preside over the meetings of council.

The council shall have power, from time to time, to frame bye-laws for the better administration of the association, and to extend its influence, but not to alter the general objects of the association. The council shall have power from time to time to determine the area of operation of the association in such manner as may seem to them best fitted to promote its objects.

The council shall appoint, and shall have power to dismiss, all paid officers of the association. All expenditure of the funds of the association shall require the sanction of the council.

All paid officers shall hold their appointments at the will and pleasure of the council.

The permanent officers shall consist of a consulting engineer or engineers, a resident engineer or engineers, a secretary, and a treasurer. The appointments of secretary and treasurer may be held by one person.

**Consulting Engineer.**—The consulting engineer shall, on his appointment, declare that he neither has, nor will acquire during the term of his appointment, any interest in any patent or manufacture connected with sanitary appliances.

He shall give advice to the council and resident engineers, when required to do so, both as to general principles and particular cases presenting any difficulty. He shall, subject to the approval of the council, lay down the general rules, to which the specific recommendation of the resident engineer must in all cases conform. His remuneration shall be fixed from time to time by the council.

**Resident Engineer.**—Each resident engineer shall, on his appointment, declare that he neither has, nor will have, during the term of his appointment, any interest in any patent or manufacture connected with sanitary appliances. The salary of the engineer will be paid by the association, as may be fixed from time to time by the council.

The resident engineer shall, in all cases, report in writing, and submit his report to the secretary, who, unless he sees reasons to the contrary, will transmit the same to the member interested.

The resident engineer shall not, as an officer of the association, recommend to the members the employment of any builder, plumber, or other tradesman. He shall not recommend to the members the employment of any patented appliances, unless these shall have met with the approval of the council and the consulting engineer.

**Secretary.**—The secretary shall, on appointment, declare that he neither has, nor, during the term of his appointment, will have, any interest in any patent or manufacture connected with sanitary appliances. His salary shall be fixed by the council.

The secretary shall keep such books and forms as the council shall from time to time direct, and he shall have the superintendence and charge of all the minute books, letter books, lists, and registers, belonging to the association, which registers shall contain a summary of the communications. He shall keep the minute books of all meetings of the association and of the council. He shall also keep a register or list of the titles of all communications which shall have been received, in the order of the dates when these shall have been so received. He shall prepare, and cause to be issued, printed circulars to all the members resident within four miles of Charing-cross, and to all such members, resident in the country, as may express a wish to have circulars sent to them, at least two days before each general, ordinary, or extraordinary meeting, containing the programme of all business to be brought before each meeting. He shall conduct the correspondence of the association in accordance with the rules which may from time to time be laid down by the council. He shall obey the instructions of the treasurer in all matters relating to finance. Copies of the reports and plans shall be submitted by the secretary to the council at each meeting, and shall at all times be open to the inspection of the members of council and the consulting engineers.

**Treasurer.**—The treasurer, or some person appointed by him, shall receive for the use of the association all sums of

money due or payable to the association; and shall pay and disburse all sums due from or payable by the association; and shall keep particular accounts of all such receipts and payments.

Every sum of money payable on account of the association exceeding £5 shall be paid only by cheque signed by the treasurer and one other member of council.

All sums of money, which there shall not be present occasion for expending, or otherwise disposing of, to the use of the association, shall be deposited in a bank, or laid out in such Government or other securities as shall be approved of and directed by the council.

The treasurer shall demand, or cause to be demanded, all arrears of annual payments as they become due.

At each meeting of the council a statement of accounts shall be laid on the table by the treasurer.

The accounts of the treasurer shall be audited annually, a short time preceding the annual general meeting, in such manner as may be directed by the council.

As soon after the audit as may be, and before the annual meeting, the treasurer shall cause an abstract of the association's accounts of the preceding year to be printed for the use of the members.

## II.—ACCOUNTS.

Balance-sheet presented at the Second Annual Meeting of the Edinburgh Sanitary Protection Association, March 30th, 1880:—

### Charges.

Balance at the Credit of the Association on 16th March, 1879 .....	£29 18 8½
Annual Subscriptions received for the year from 16th March, 1879 to 16th March, 1880—	
412 at £1 1s. each .....	£432 12 0
26 at £2 2s. upwards .....	70 7 0
Sum .....	502 18 0
Interest on Bank Account to 31st December, 1879 .....	1 10 2
Sum of the charge .....	£534 7 10½

### Discharges.

#### Salaries of Officials—

To Professor Fleming Jenkin as Consulting Engineer .....	£52 10 0
To Mr. Welsh, Resident Engineer—	
One month at £150 per annum .....	£12 10 0
Eleven months at £170 per annum .....	185 16 8
Sum .....	198 6 8
To Captain Douglas, as Secretary .....	100 0 0
Sum .....	£320 16 8

To Tradesmen for assisting Resident Engineer at Inspections .....	11 14 6
To travelling expenses of Resident Engineer .....	1 8 8
To Office Rent and Taxes .....	87 18 10½
To Stationery .....	6 11 1
To Advertising and Printing .....	38 16 0
To Furniture and Removing Office .....	10 9 1
To Collector's Commission at 5 per cent. ....	6 7 6
To hiring Masonic-hall .....	1 1 0
To Charwoman for year .....	11 12 0
To Postage and Sundries .....	14 8 7
Sum of the Discharge .....	£460 18 11½
Sum of the Charge .....	534 7 10½

Balance in favour of the Association .....

“Edinburgh, 30th March, 1880.

“I have examined and audited the foregoing account, and I have found it to be properly and sufficiently vouched, and correctly stated, and there is a balance of £4 7s. 6d. due by Captain Douglas, as on the 16th March current. I have prepared an abstract of the accounts, to which I beg to refer, and from which it appears that, in addition to the above balance, there is also a balance due by the bank of £69 1s. 4d.

“THOMAS SCOTT.

“30th March, 1880.”

## DISCUSSION.

The Chairman, in inviting discussion, indicate as briefly as possible how his name placed in the honoured position which it head of the association. He felt in that position like the proverbial “fly in amber,” an extreme stretch of the term “natural history of which was his proper business, he did sanitary inspection could be included in it. rest of the world who had any knowledge gical matters, or any conception of the la had always taken a sort of theoretical int tions of sanitation; but there was a wi between a theoretical and practical inter was brought home forcibly to his three years ago, when suddenly, with three of his children were struck do theria, and one of them lay a long time and death. This was a lesson which turn tion more strongly to the importance of t sanitation than all the mere talk about it heard. He became deeply interested in condition of his own house, which was well situated, and in which, he thought, precautions had been taken. It turned investigation of the history of that very demic, that it was not his house which w all. His children were poisoned through most careful inquiry, which was made s the officers of health, left a keen conviction—although the evidence did not exact proof—that the fault certainly did no house, or in those of a large nu neighbours, who were many of them mu with by the epidemic than he was, but t of the whole mischief lay in a preposterous to the conditions necessary to be attended draining a large and populous district. of pains with the question at the time, that if ever he could serve the cause of any way he would do so, and would do could to bring before the mind of the pul amount of vividness which was necessary unless sanitation was attended to in c like London, before long they would be diseases introduced, by their own contriv own houses, on a larger scale, probably, cities of old by plague and pestilences o He was glad to be able to do anything fact before the minds of the people of L get them to do as Professor Jenkin had take ordinary means for protecting them looking for extraneous help. It was o that he had consented to join the comm only regretted that the council had tho him forward as their representative and c could not do much in that capacity, but to say that when once the society was in there would not be very much for eithe council to do; at any rate, what little which he could do, should be done to t ability.

Sir Henry Cole, K.C.B., thought every o that if they were to get sanitation in Lon do the work themselves. He had had a perience of Vestries, and he saw no salvi He had been before the Metropolitan Bo was politely asked if he ever read Acts c as there were such extensive powers for thing right. He had been to the Pri Local Government Board, and pointed o the street in which the present Prime had been found to have half its house with the sewer at all, and all he got was sympathy. The Society of Arts had bee

for the last seven or eight years, in the only soil, and at least it had actually done more. The present Council having determined to do additional conveniences to the members, an expert to inspect the premises, who, as they expected, that their sanitary state was as bad as could be. The Society is a pioneer in this work, it undertook to public, and afterwards to give lessons to Parliament, and, to some extent, there might claim to have helped on Professor Rawlinson. There was, however, more than one the field. Going back a little, Mr. Crosswell forwarded the idea of a sort of sanitary high people might incur, then came the work, and then came the Parkes' Museum, then there was the Sanitary Institute, Health Society, and a Ladies' Sanitary Association, these to show what a deal of required before you could get up enthusiasm any anything into operation. Earlier than as there was Dr. Farr, Mr. Chadwick, and as now present (Mr. Rawlinson), who went on to help to make the troops a little then they would have been without him, all of the Society had it under consideration three medals to the proprietor or she should produce three good houses in which should be held up as illustrating the most upon correct sanitation. No doubt all be some difficulty in the matter, but the had would be thus directed in the right road, so as going to Parliament until they could then, and that would not be until constitutions in the country insisted on their members paying to the question of health.

Rawlinson, C.R., said he most heartily wished the association now started, which he had would do a great deal of good. Professor of sustained pipes within houses, traps, and ; but when houses were dealt with as they ought to be, there would be no drain-pipes within them, and would have very little, if anything, to do with it was quite possible so to arrange the largest that there should be no drain-pipe within its walls, and so need for the intervention of any The whole of the apparatus might be of iron. As to improvements, he would only say that from the Egyptians called in experts to embalm of their dead, but when they had perished in question, they had to escape for their he feared that the sanitary engineer of upon somewhat in the same light. did upon to advise, but if he were an honest the premises were in a very bad state, it was summary that he should turn them inside summary cost a large expenditure of time, and caused a great deal of personal inconvenience, and he could assure the meeting that the cordially hated that man by the time he his work. Before that association or any of, he had probably done as much gratuitous this kind as anyone, for he never respond to an application for advice on them, from any person who came to him situation from a personal friend. But he had found that persons possessing wealth set re by it, and thought so little of their own effort and health, to enable them to enjoy that they put away the idea of spendable sum, and suffered the rats, and and the rot to go on, and went to their way had begun. There was now a great amongst the dry bones of ignorance through- and a paper of this description, when dis- sistent, was calculated to do a great deal of had no doubt the association also would

do good. The apathy in this matter more frequently came from the father than from the mother, as he was not within the building perhaps more than five or six hours out of the twenty-four, and they who suffered most from the bad arrangements were the delicate children, ladies, and those who were living on the premises. One after another the children might be seen falling into consumption, and fading away before a father's eyes; but he might be ignorant of what was the cause, and let evil go on day after day. He (Mr. Rawlinson) would tell them that, according to his experience, the cause of ill-health throughout the length and breadth of the civilized world, even in malarious districts, was not so much in the atmosphere, not so much in the earth, not so much in the swamp, as in the habits of the people, and in their foul dwellings. Probably he could speak with as ripe a knowledge as any man. He was a member of the Army Sanitary Commission—a body of which the public knew nothing. The Quartermaster-General of the Army, for the time being, was always the chairman, and it included besides the Second Medical Officer of the British Army, the Royal Engineer quartered in London, the Chief Medical Officer from India, and one of their chief engineering officers. They had returns coming in regularly. Wherever a British soldier was quartered on the face of the earth, they had returns as to the climatic influence and the conditions under which he was living, so that he (Mr. Rawlinson) was justified in drawing the conclusion he had mentioned, that it was not so much the climate as the conditions of life which made the difference. As the meeting was aware, he was one of a Commission sent out to the Crimea, where such a mortality prevailed as had never previously been known. The Russian retreat was not so bad, the Walcheren expedition was not so bad. Some regiments lost 700 men out of 1,000 in three months. The Commission found those hospitals reeking with filth—the man living under the worst possible sanitary conditions. Some persons blamed the military and medical authorities, but they really were not so much to blame, because those wonderful regulations, which were tied up with red tape, prevented anything being done. The Commission to which he belonged went out, however, entirely unfettered; their instructions would be found in Kinglake's last volume, and that author spoke most highly of them. So did the American Sanitary Association, which was founded on the model of theirs. They were not fettered in what they ordered or what they expended, and the result was that, by simply carrying out cleansing operations, in three months they brought the mortality in those hospitals down from about 16 or 18 per cent. to 1½ per cent., and by the end of the summer the entire British army in the Crimea was healthier than ever it had been in barracks at home. At this moment he might say broadly, that whereas previously to 1855, the returns showed that the army had suffered at the rate of 17½ per 1,000, and in India, 69 per 1,000, since improved sanitary regulations had been carried out, the mortality at present was less than 7 per 1,000, and, in India, less than 20. He had not a shadow of doubt that London, wonderfully healthy as it was, might have its mortality considerably reduced, and he would give a case in point. In Leeds, some years ago, he found the sewers were not ventilated, and the rate of mortality was high. Fortunately, they had now an exceptionally intelligent engineer, and he had done what ought to be done generally, he had not only ventilated all the main sewers, but he had untrapped every gully. The result was, there were 20,000 gullies which had no traps, and the combined area was equal to something over 3,500 square feet always open to the atmosphere. By the last returns, the mortality was reduced to about 19.9, whereas last year it was 25.5. If there was one thing more difficult than another, it was to induce people to ventilate the sewers and drains.

There were towns which persistently bottled up their sewers, because if they made one opening, they said it stank so abominably—and so it did—that they shut it up again, instead of opening 20, 50, or 100 others. He had recently reported on Dublin, which had 400 ventilators on their main sewer, whilst he ascertained that to make them safe they ought to have 3,000. This question was at the root of sanitary improvement. Any house having drains within the four walls which had openings into them was not in the condition it ought to be. If a drain must traverse the basement from back to front, as in many cases it must, he would resort to an iron pipe with a ventilator behind, he would cut it off the main sewer in front, and bring the communications with the sinks and closets into it outside the walls.

Mr C. W. Crosswell said that every lover of sanitary progress must sympathise with the efforts of Professor Jenkin and Professor Huxley, to promote the real well-being and health of the people; and, of course, those who had been conspicuous in that Society in the promotion of the good cause, rallied to support an excellent effort, however small it might be compared with the magnitude of the evil with which they had to cope. With that view he had come over from Paris to pay his small tribute to the man who had come from the seat of learning in the north to help Londoners in the cause they all had at heart. But he must confess that he was somewhat disappointed by the almost insignificant proportions of the weapon with which it was proposed to deal with the enemy. It was a very thin end of the wedge, and he cordially agreed with the remark of Professor Jenkin that it was probably only one step towards general compulsory inspection. In that sense he welcomed it, and if it tended in any way to serve that cause it was worthy the support of every lover of his country. The very title of the association showed that it must be of very limited operation, and, by the rules, it appeared that it was confined to domestic sanitary protection. Now, sanitation was a very large subject, and went far beyond the limits of the mere household. There were other causes, other evils to which attention had often been called there, which he wished some grand association might be promoted to deal with and repress, and, therefore, he felt that, surrounded as they were by a most unsanitary atmosphere, physical and moral, on this subject, it would have been well if the association had been so formed as to enable it to deal with the difficulty in a far more radical and drastic mode. However, it would be ungracious to pursue that line of argument any further. They ought to be grateful for even the smallest morsel, and to thank those who came forward with their time and scientific reputation to assist. But after all, how little could they do in such a metropolis as this. During the three years the association had been in operation in Edinburgh, admirably organised and well supported, they had succeeded in dealing with 1,200 houses only. In London he believed there were 400,000 or 500,000 houses; they were increasing at the rate of 60,000 to 70,000 per annum, and out of those new houses built every year 50,000 were unfit for human habitation. That showed the evil with which they had to cope. Some allusion had been made to his own efforts; he had the honour in June last of propounding a scheme which should have the sanction and co-operation of every County Board—such as they might have some day—every municipal authority, and every public body which had the right to exercise such powers as would be necessary; he had the support of the Right Hon. Mr. Stansfeld, Dr. Richardson, Dr. Voelcker, authorities recognised everywhere, and the unanimous approbation of a crowded meeting, and what had been the result? It had been absolutely ignored as far as public opinion went; nobody condescended to notice it. Possibly the seed he sowed was bad, possibly it fell on barren ground; possibly it was choked with the weeds of prejudice; possibly it was not watered with what was

necessary to growth in anything—a strong local public opinion, but from one cause or "unmarried are it saw the sun." This seed it had fallen—died, as Shakespeare said of the hoped, might have a more prosperous career. were to have County Boards in Ireland, and, when Irish affairs were settled, they might have in England, and it was through County Boards great municipal bodies he hoped to see some; step taken even than this. The first step was an attempt to supersede the miserable apologetic government called the Metropolitan Board of and the Corporation of London. Let them seek the metropolis a form of government from common sense, and invest the governing body with power to compel, in the sense of passing laws, every householder to obtain that which he desired and every municipal right to enforce that which was absolutely essential for the welfare of the public.

Mr. J. I. Traay advised people not to rely on public aid, but for each one individually to look to his own interests. He considered that great engine surveyors had done an immense deal of mischief, works they had carried out.

Mr. Rogers Field agreed in the main with Rawlinson's remarks. The point he felt a deal about was the possibility of giving adequate time for the terms mentioned. His experience showed work of this character required a great deal of the careful inspection throughout, and unless it was thoroughly well done, harm instead of good result. He gave an instance where he had been called after a case of typhoid fever; but his recommendations were not fully carried out, on account of the expense and the consequence was that fever again. Eventually the work was thoroughly done, the house became healthy; but if it had not been completed, it would have been said, "You called a surveyor, you spent a great deal of money, the house is as bad as ever;" and he could not see anything more likely to injure sanitary science such a state of things. Since then he had no rule, if his clients would not do what he considered necessary, to have nothing to do with the case.

Mr. E. C. Robbins did not sympathise with the remarks of Mr. Field, who did not seem to understand principle they proposed to act upon. He said Professor Jenkin had shown that the household difficulty was, not that he did not know some principles to be observed, but he did not know how to apply them. It was an expensive affair to call in Field, and there were thousands of people who could not afford it, but were they not to have good advice at all? They were not responsible for people not taking good advice, or stopping in the middle of a job saying they would not do any more. They owed of gratitude to Professor Jenkin for showing the feasibility of this scheme in Edinburgh, where houses had been put into good order under the vision of the society, who charged no more than one guinea, or two at the outside. That was the wanted in London, and the more they had of better. There were plenty of practical men to carry out the instructions given to them; the some honest tradesmen, and it was a false conclusion to come to, to say that nothing effectual could be done unless there were perpetual inspection by highly paid surveyors. He had had as much experience as most of bad work, and knew how important it was to have the proper participation between the owner and the man, which would make them all feel interested in doing out the work in the best possible way. He had personal experience of the usefulness of the Edinburgh Society, for his friend, Professor F. St. Andrew's, got their engineers down to his house, and had the recommendations carried out.

men; it was afterwards inspected, and any set right, and the result was most satisfactory. hope, therefore, that the plan would receive all the attention it deserved.

Waters said this subject was of the greatest importance, and perhaps medical men could speak on that more strongly even than engineers. It was not rent diseases which were brought into the house by sanitary defects, but minor affections, such as head-aches, sickness, diarrhoea, &c. It seemed to him, however, that the scale of payment was scarcely adapted to London, as well, perhaps, as to Edinburgh. A house of £60 a year, near Charing-cross, would be much less than one of the same rent five miles away, and the amount of work to be done would be very different; the same fee was charged. He was a director of the Sanitary Association, which based the fee charged on the number of water-closets in the house, and this he considered preferable.

White gave a practical instance of the usefulness of the Sanitary Association. He knew a house which had been in a most unsanitary state ever since it had been built, and he was advising the occupants to give up that they should not continue in it unless it was put into a sanitary condition, to the satisfaction of the engineer of the association. He had felt for many years the helpless condition in which they were placed with regard to these matters; he had again endeavoured to get landlords to set it right, but they had shirked it. It would be no use to them practically if they received notice that their tenancy would not be continued unless they put the house into a sanitary state. He could not but think that in a few years, the association having shown its usefulness in a small sphere, it would by degrees induce the Sanitary and Local Boards to take up the question, and that local associations of the same kind in each district would do the work which one body could never so large an area as London.

William Botly wished to say a word in corroboration of the views expressed by Mr. Rawlinson. In some cases he had had all the pipes removed from the house, and the water-closets also put outside. The estimate was £25, but improvements were made for the use of the work, which brought it up to £72; but no money was ever better laid out.

Mr. Collins, having had 26 years' experience with the Sanitary Association, could only come to the same conclusion as Mr. Rogers Field, that the fee charged was adequate for anything like a proper inspection, and for a skilled workman. That very day he had been estimating a house of about £150 a year rent, and the drainage had been laid open on the previous day, and he had been in the morning until half-past six in the afternoon in order to get the data for the report, the writing of which and preparing the estimate would occupy him three or four hours more. It was not possible for a professional man of any standing to do work for anything like the sum named. It was very well to have theory, and you could not do without it, but in these matters you also required practical extensive experience, for nearly every house had peculiar conditions. No young man would be able to deal with such matters satisfactorily, and the name of an eminent engineer were attached to the report, which he had not been personally prepared, it would only do more mischief than good in the end.

Mr. Jenkin, in reply, said he had endeavoured to avoid anything which could be called sensationalism, and to describe the evils under which they laboured, and to show that every one present there, at any time, was fully sensible of those evils. With reference to Mr. Rawlinson's remarks, he could only say that the Sanitary Association had attempted to deal in the first place with the cause of the evils; they had to look at houses as they

existed, with a good many pipes inside them. If they came forward and told every householder that all those pipes must be taken out, very few people would consult them, and they would not do nearly so much good as they might. There might be a good many healthy houses in which there were some pipes, although he cordially agreed with the principles laid down, that if you were to design a new house, the mode suggested was the proper one. In reply to Mr. Cresswell, he could only say that the association was a modest one; it did not propose to do everything; but only something—and something practical. There was only one point in the description to which he felt it necessary to seriously address himself, and that was the one raised by Mr. Field and Mr. Collins. It was one he had answered to some extent by anticipation, because he expected it. Mr. Collins was present at the meeting of the Social Science Association at Edinburgh, and he (Prof. Jenkin) also came there from abroad for the purpose of discussing this very question. The association had been started in Edinburgh, where he was known and, to some extent, trusted, and the same difficulty was raised at the outset, but a great many people put some confidence in him, and that confidence had not been misplaced—at any rate, no one had made any complaint. He attended the Social Science meeting because he thought a great many engineers would come there and hear what had been done, and they would have the opportunity of challenging the success of the association and the thoroughness of the work. Mr. Collins heard his paper read, and heard several persons speak upon it; he heard the opinions of the medical officers of health, and of Sir Robert Christison in favour of the association, but no one got up to say the work was not thoroughly done. Mr. Collins did not get up then and say what he had said now, or he would have been met with a very different answer. The books were open to him, why did he not go and look at them? How dare anyone who had had an opportunity of consulting these reports come there and tell him in effect that he, a member of the Institution of Civil Engineers, was offering something which was a sham and a delusion? He had some reputation, and he was not going to stake that reputation on anything he could not support. He did not come to London until the thing had been at work three years in Edinburgh—until he could come forward, not only with a hope which justified him in beginning the work, but with a certainty. He could read any number of letters on the subject, but it would be merely self-laudation. He had done enough to justify him in asserting that they could do good work, small as the price might be. If he did not, he was fully alive to the responsibility he should be incurring by giving a sham inspection, and a sham report, which would be good for nothing, if not worse than nothing. All he could say was, give them a trial; if the work was badly done, they would not be tried again; bad work could not possibly live. Let all associations with the same object flourish; let some charge more and some less; let those who could afford to pay fees to engineers of eminence for personal attention continue to do so, but until some case was proved of inattention or of inefficient work done by that or any other association which worked cheaply, engineers should not get up to say the work would be badly done.

The Chairman then proposed a vote of thanks to Professor Jenkin. The statement he had made was so clear and definite, that if it turned out to be correct he would assuredly reap the credit which he deserved; while, if it proved incorrect, it was so definite that there could be no doubt about the matter. They might also thank him for the very vigorous and, at the same time, good-tempered defence he had made of his position.

The resolution was carried unanimously, and the Proceedings terminated.

## CANTOR LECTURES.

SOME POINTS OF CONTACT BETWEEN  
THE SCIENTIFIC AND ARTISTIC ASPECTS  
OF POTTERY AND PORCELAIN.

By Prof. A. H. Church, M.A. Oxon., F.C.S.

LECTURE IV.—DELIVERED MONDAY, DEC. 13, 1881.

*Soft Paste Porcelains, European and Oriental.*

Softness, as tested by the file, or by a fragment of quartz (or even felspar), and by fusibility in the kiln, generally go together in the case of translucent wares, usually known as porcelain. No exact classification of these pastes, or bodies (which, after all, are mere mixtures, variously and often capriciously compounded), is possible. But it is not without reason that the glassy, the felspathic, the phosphatic, and the kaolinic constituents which characterise certain wares, should be regarded as determining the species or kind of porcelain to which they severally belong. But difficulties in classification after this fashion are always arising, when one has, for instance, to find a place for such a composition as the soapstone body of early Worcester ware, and the glaze-formed porcelain of Persia. A word about the latter, as the only kind of Oriental soft porcelain, and far older than any European translucent ware, may serve as introduction to to-night's discourse. This Persian porcelain occurs almost exclusively in three forms, namely:—(1.) Small white vases, bottles, and cups without other decoration than surface-mouldings; (2.) Open shallow bowls with rice-grain perforations filled in with the glaze, and often decorated with sparse simple lines of black, brown-purple, or blue; (3.) Bottles, cups, and other vessels having a blue ground and lustre decoration. The specimens of the first and second groups, and occasionally those of the third, consist of a highly silicious granular paste, or body, washed over with a small quantity of a kaolinic substance, and rendered porcellaneous, and remarkably translucent, by means of the penetration of the glaze into its whole substance from both surfaces. It may be compared to a piece of cartridge paper which has been thoroughly varnished, so far as the cause of its translucency is concerned. It now transmits a great part of the light which falls upon it, instead of regularly reflecting much, and "scattering" (by innumerable small irregular internal reflections) more. This ware has been fired at a low temperature, and shows, wherever the glaze has not saturated the body, how porous and fragile the latter is, and how easily discoloured. Pieces of Persian porcelain, belonging to group 2 above, were known in England as Gombroon ware. There are characteristic specimens both in the British Museum and in that of South Kensington.

Let me now direct your attention to the beginnings of the manufacture of porcelain in Europe. Of course, both hard and soft paste were inspired by the desire to reproduce the delightful material which the Chinese had so long made, and had adorned so exquisitely. The first approximate success was reached in the Medici translucent ware, which dates from 1581. In this three materials were associated, namely, the porcelain-clay of Tretto, near Vicenza, a fine sand, and a glassy frit. Specimens are extant at Sèvres, and in some

Italian museums. Of the porcelain said to have been made at Venice as early as 1519, no aut specimens have been recognised, but some pieces of the period 1720-40 are known; the of a very translucent glassy character. Cos the better of two Venetian porcelain mak the later period (1765). It is curious to not the use of binocide of tin in glass makin influenced much of this Venetian porcelain. smooth milky white, sometimes densely aspect, associated with a high degree translucency, is to be attributed to the duction of a stanniferous enamel. At l a soft paste porcelain was made in and at Capo di Monte, Naples, in 1736. workmen from the former factory intr the manufacture of soft porcelain into (Buen Retiro) in 1760. On studying the pan glaze of these Spanish and Italian porcelai is able to discern in some measure those r between them which are due to the impac of methods, if not of materials, from one another. The soft paste made at Alcorta, in differs from that of Buen Retiro, as might e pected from the circumstance that its manuf was introduced, not by Italians from Cap Monte, but by Germans from Dresden.

Belgium was somewhat late in the manuf of porcelain, but Peterynck, of Lille, mix plastic clay with a clay marl and a glassy obtaining thus a tenacious and durable paste. "privilege" dates from April 3rd, 1751. factory at Tournay was a success. Marienb Sweden, possessed a small works, where soft porcelain was made. Of these wares, and of which were manufactured at divers small plac Switzerland and Austria, there is little known, nothing that I need here mention, for we have to discuss all the more important points nected with such productions, when speaki those which were turned out from English French factories.

And here, perhaps, I may suitably direct you tention to a subject on which much misappreh exists. Although in true hard porcelain, if w colour, both Oriental and European, a hard and a hard glaze go together, it is not unus find a great range of degrees of hardness in glazes upon the so-called soft porcelains; for, vided the difficulty of unequal contraction be mounted, there is nothing to prevent a soft very fusible glaze, rich in alkalis or lead, being applied to a china body of a considerable degree of hardness. So, on the other hand, finds the soft, porous, nearly opaque body of Bow porcelain, coated with a glaze much easily abraded than itself. The one conditio be fulfilled is the greater resistance to the so ing and fusing effect of heat, which the body enjoy when compared with the glaze. It is u ful to bear these facts in mind, when examin piece of porcelain which is said to be "soft pa Ascertain, by a file, or a piece of quartz or fel the hardness of the paste on some portion of vessel free from glaze, and do not be content any signs of attrition which the glaze may s And it may be further noted that the removi enamel colours by wear is by no means a sig the porcelain body beneath being soft paste, points rather to the hardness of the glaze, or t

ature at which the painting on its surface fired.

in returning to the subject of soft paste of foreign manufacture, I would direct attention to the French works, as illustrated specimens before you. You will notice the ones which the productions of certain of these factories bear to each other. You see the remarkable translucency, and almost surface, of the early wares of St. Cloud, and of the Faubourg St. Honoré, Paris. Here allied products of Chantilly, and Mennecey, Orleans, and Sceaux. The employment of numerous washes to whiten the body, of the early Chantilly porcelain with that of a chronological list of the chief French exhibits many points of interest, when representative specimens of each side by side.

St. Cloud.	1753. Orleans.
St. Amand.	1753. Sceaux.
Paris: Faubourg	1756. Sèvres.
Moret.	1768. Etioilles.
Chantilly.	1773. Bourg la Reine.
Mennecey-Villeroy.	1784. Arras.
Orléans.	

these factories produced good wares, of technical skill, of artistic knowledge, of able raw materials, offered in some cases backwards to assured and permanent success. Works at Vincennes were started about a few years were engaged in futile or, until about 1745. In 1753, they ceased, and in 1756 transferred to Sèvres. The body of the *Vieux Sèvres*, the pâte of eight parts marl, and seventeen associated with seventy-five parts of a and covered with a lead-glaze. I give a relation of the frit and glaze, that the subsisting between the composition of soft paste, and that of many English is apparent.

The frit consisted, in 100 parts, of—

parts .....	} fused together and then washed.

, after having been baked, was glazed and on the colours were applied by dusting glazed surface, which had been previously with a thin film of fat oil of turpentine. pieces are fired, and the process of the enamel colour is repeated—the fired again. By repeating these two several times, the fine coloured grounds of Sèvres was famous, were obtained. The, often marbled and veined with gold, use; the bleu turquoise was invented and the rose carné, or Pompadour, the ée, the vert pomme, jaune claire, vert rt jaune, in 1857. The special beauty lies not in the intrinsic excellence of

the enamel colours, though this is high, but in the penetration of the glaze by the enamel ground-colours, and the rich but soft effect thereby produced—an effect which is enhanced by the special qualities of the soft and fusible paste beneath.

From old Sèvres let us turn to old Chelsea, the earlier productions of which show the presence of much vitreous matter, like the soft paste of the French factory. The date of the Chelsea works is not known. As, however, a high degree of excellence had been reached as early as 1745, evidence of this being afforded by the three specimens of “bee milk jugs” known to exist, all marked with an incised triangle and “Chelsea, 1745,” engraved in the paste, it is incredible that the manufacture could have originated in that year. We know that in 1747 some Staffordshire potters went to Chelsea, but the notion that any improvement can be traced to this source is obviously erroneous. However, it would appear that they soon left the original factory, and set up an establishment of their own. We have data for arranging the productions of Chelsea according to these periods:—

Period I.—1745 (?) to 1757.

Period II.—1759 to 1769.

Period III.—1769 to 1784.

During period I., the porcelain was characterised by considerable translucency, much glassy grit being employed in the paste, and the glaze being also very soft. During the second period, the colouring was soft and yet rich, but the ware was less glassy, and the glaze rather more greenish. Towards the middle of this period (1764) Nicholas Sprimont, the owner, tried to sell the factory. It was then in most active operation, for a single year's production (over and above private sales) took sixteen days to dispose of by public auction. The catalogue of that auction comprised over 1,600 lots, and more than 6,500 pieces. In 1757, the works slackened and then ceased, the manufacture being resumed in 1759. From that date, all the ware was phosphatic; that is, it contained much bone-ash in the body, while the use of gold in decoration became more frequent and more lavish; figures with gilding upon them are not, indeed, so much as named in the sale catalogue of 1756. Here I may name and show you a peculiarity of the early Chelsea body (of period I.), which was, I believe, first recognised by Dr. Diamond. This white leafy saucer illustrates the characteristic to which I refer. On looking through it at a candle, we notice a number of moonlike discs scattered throughout the piece, and much more translucent than the rest of the body. They seem to be due to an irregular and excessive aggregation, in fact, of the vitreous frit which formed so large a constituent of the early Chelsea ware. Typical specimens of the second period are seen in the large vases (1764) in the British Museum; in the third period, when the works were in the possession of W. Duesbury, of Derby, the style became more ornate, and, in many instances, indistinguishable from that of Derby. Some suggestions as to the materials employed at the Chelsea works may be gathered from the following statements in Grosley's “Tour in London,” “the sort of earth fit to make porcelain” was supplied by Cornwall to Chelsea: pounded glass was then used, and sand from Alum Bay. It will be recollected that Dorset

clay had been worked as early as 1666, and the clay of Bovey Tracey as early as 1730. But chemical analysis of authentic specimens of Chelsea confirms the separation I have made of Chelsea china into three periods, which may be respectively designated as—

- I. The vitreous.
- II. The phosphatic,
- III. The kaolinic.

Something more about this will be seen further on.

Let us now turn to another famous English factory, that of Bow. The introduction of the characteristic constituent of what is often called by Continental authorities "natural or English soft porcelain," is usually attributed to Josiah Spode the younger, son of that Josiah Spode who, at first a workman, rose to considerable position and wealth, and who died in 1797. His son soon afterwards began making porcelain, and attained great excellence in smooth uniformity, truth of form, and fineness of glaze. He died in 1827, his partner, William Copeland, having died in 1826. Josiah Spode the third was the second son of Josiah Spode the second, but he only survived to carry on the porcelain manufacture for two years, his older brother, J. Hammeraley, being in business in London as Spode, Son, and Copeland. In 1833, S. T. Copeland bought the works at Stoke belonging to Spode; afterwards the firm became Copeland and Garrett.

It will thus be seen that no Spode porcelain can be earlier than 1797, probably not much earlier than 1800. If, then, we find phosphate of lime in porcelain of an earlier date, and of other manufacture, Spode's supposed introduction of bones into English porcelain paste—in fact his supposed invention of "natural or English soft porcelain"—falls to the ground. Now, chemical analysis of many specimens much earlier than any of Spode's make, proves this to have been the case. Bow, Chelsea, Worcester and Caughley, are all alike in this particular—all contain phosphate of lime from bones. The excavations in 1863, at the works of Messrs. Bell and Black, revealed many unglazed fragments and wasters which must have been made on the spot; some of these I have analysed completely, others I have tested; all tell the same tale. The patents speak in the same way. The 1744 specification of Heyly and Frye gives one part of potash, one of sand or flint and unaker. In 1749, T. Frye's patent names, in lieu of unaker (an earth from the Cherokee territory, U.S.), a virgin earth, produced by the calcination of certain "animals, vegetables, and fossils." This is directed to be mixed with flint or sand, and a certain proportion of pipe-clay. The glaze was made of red lead, saltpetre, and sand, with some white lead and smalts. There can be no difficulty in identifying the earth produced by the calcination of certain animal and vegetable matters, as bone-earth, or calcined bones, which is essentially phosphate of lime; but the patentees did not desire to be too explicit. Here are the analytical results confirming this deduction. They are obtained by means of a careful chemical examination of some fragments of unglazed porcelain of obviously early period, disinterred during draining operations at the works of Messrs. Bell and Black, at Bow:—

	Per cent.
Silica .....	40
Alumina, with a little oxide of iron ....	16
Lime .....	24
Phosphoric acid .....	17
Soda .....	1
Magnesia .....	1
Potash .....	1

The resemblance between the Bow and Chelsea porcelain of the second period is confirmed by analysis of the latter which I have made. I have given me about 40 per cent. of silica, 16 per cent. of phosphoric acid; but the Bow is softer, indeed it may be easily cut with a and the glaze, which takes colours well, is *piqué avec points noirs*. The bottoms of vases cups of Bow are often heavy and uneven, frequently they have been ground level. Caughley specimens, all Pennington's, Staffordshire, and many Worcester, contain phosphate of lime, little use can be made of the applied molybdic acid test for phosphoric acid in order to determine the origin of a piece of old paste porcelain.

The Bow factory was an extensive one; according to Craft's well-known inscription in British Museum, 300 hands were there employed. It may have been established earlier than the date of the first patent (1744), some say in 1730. Its characteristic qualities, from an artistic point of view, of its productions resemble those of Chelsea porcelain, but they were not developed to the full extent possible; the transition into the glaze of the enamel colours, the warm luminous quality of the paste, are considerable features in Bow porcelain, but the porosity of the body admitted of the ready absorption of grease, and of accidental colouring stains, which caused unsightly disfigurements. From what I have said, it will be evident that the characteristic ingredient of Bow porcelain—bone ash or phosphate of lime, which subsequently came into general use throughout the country.

A few of the recorded recipes for the manufacture of the body of ordinary English porcelain during the last 40 or 50 years, will serve to show the important part which phosphate of lime has in this composition:—

	I.	II.	III.	IV.
Bone ash ..	47	46	46	40
China clay ..	34	23	23	30
China stone ..	28	31	31	30
Flint .....	—	—	—	—
Felspar ..	19	—	—	—
Glassy frit ..	3	—	—	—

Analyses of modern English porcelain, about 1840, gave:—

Silica .....	40
Alumina .....	23 to
Lime .....	10 to
Phosphate of lime and iron .....	15 to
Alkalies .....	2 to

Thus far, I have spoken almost exclusively of productions of Chelsea and Bow; a third English factory demands some attention. Worcester stands by itself in more particular one, but its survival for 130 years alone sets it from all other English factories in an exceptional way. In order to study the products of the Worcester works intelligently, it is necessary

changes of style and taste which occurred to time in the history of the porcelain it is also necessary to observe the success of composition, and consequently both in body and glaze. A convenient arrangement of the Worcester periods

Old.	Modern.
1751 to 1772.	IV. 1793 to 1807.
1772 to 1783.	V. 1807 to 1813.
1783 to 1793.	VI. 1813 to 1840.

artistic point of view the works of the greatly transcend those of the modern. The glazing, and the hard over-precise finish, and the productions of the closing years of the eighteenth century and of the later time, have deprived the decoration of Worcester all its original softness, freedom, and the painters and gilders seemed to have been trying to emulate the rigid exactitude of mechanical processes, which were coming day by day into vogue. And they succeeded very well in expressing the human element of their art, and in making it gorgeous, precise, and lasting.

And, through the kindness of Mr. R. W. Minton, learned and talented director of the works, to give you the recipe for the body of the earliest body made at Worcester; the True Secret of Making Worcester porcelain, a secret supposed to have been lost. The body was a mixture of a prepared mass and other ingredients.

#### Worcester Body of 1st Period.

.....	5 parts.
.....	5 "

The used at Worcester in the second period was—

.....	38 parts.
.....	27 "
.....	11 "
.....	15 "
.....	9 "

The supply of "soapy rock," that is, other hydrated magnesian silicates (from Mullion, in Cornwall) was used, which is still largely used at Worcester.

We went on to describe the peculiarities

of several specimens of old and modern Worcester porcelain, which were on the table.]

The following list of potteries where soft paste porcelain was made, is instructive in many ways, but has no pretension to completeness. The history of almost all manufactories has been a chequered one, and many have enjoyed but a very brief existence:—

1745 to 1849, Derby.	1795 to 1812, Pinxton.
1751 to —, Worcester.	1813 to 1820, Nantgarw.
1756 to 1802, Lowestoft.	1814 to 1817, Swansea.
1772 to 1814, Caughley.	1820 to 1842, Swinton.

[The lecturer proceeded to illustrate the peculiar qualities of the porcelains produced at these factories by means of specimens on the table.]

I cannot conclude without expressing my best thanks for the loan of specimens, new and old, to Messrs. Minton, of Stoke, to Mr. R. W. Binns, of Worcester, to Messrs. Phillips, of Oxford-street, and to Mr. Litchfield, of Hanway-street.

ERRATUM IN LECTURE III.—The figure 3 has been dropped, during printing, from the formula  $\text{Fe}_2\text{O}_3$ , on page 107, line 3.

### MEETINGS OF THE SOCIETY.

#### ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

JANUARY 19.—"Causes of Success and Failure in Modern Gold Mining." By ALFRED G. LOCK, F.R.G.S. HYDE CLARKE, Esq., will preside.

JANUARY 26.—"Five Years' Experience of the Working of the Trade Marks' Registration Act." By EDMUND JOHNSON.

FEBRUARY 2.—"Trade Prospects." By STEPHEN BOURNE.

FEBRUARY 9.—"The Present Condition of the Art of Wood-carving in England." By J. HUNGERFORD POLLEN.

FEBRUARY 16.—"The Participation of Labour in the Profits of Enterprise." By SEDLEY TAYLOR, M.A., late Fellow of Trinity College, Cambridge.

FEBRUARY 23.—"Recent Advances in Electric Lighting." By W. H. FREER, Pres. Soc. Tel. Eng.

MARCH 2.—"Flashing Signals for Lighthouses." By SIR WILLIAM THOMSON, LL.D., F.R.S.

MARCH 9.—"Improvements in the Treatment of Esparto for the Manufacture of Paper." By WILLIAM AENOT, F.C.S.

MARCH 16.—"The Manufacture of Aerated Waters." By T. P. BRUCE WARREN.

MARCH 23.—"The Increasing Number of Deaths from Explosions, with an Examination of the Causes" By CORNELIUS WALFORD.

Dates not yet fixed:—

"Buying and Selling; its Nature and its Tools." By Prof. BONAMY PRICE. On this evening Lord ALFRED S. CHURCHILL will preside.

"The Discrimination and Artistic Use of Precious Stones." By Prof. A. H. CHURCH, F.C.S.

"The Compound Air Engine." By Col. F. BEAUMONT, R.E.

#### FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

FEBRUARY 1.—"The Industrial Products of South Africa." By the Right Honourable Sir HENRY BARTLE FRERE, Bart., G.C.B., G.C.S.I., D.C.L., LL.D., F.R.G.S., &c.

FEBRUARY 22.—"The Languages of South Africa." By ROBERT N. CUST.

MARCH 15.—"The Loo Choo Islands." By CONNELL JOHN A. GUBBINS.

APRIL 5.—“Trade Relations between Great Britain and her Dependencies.” By WILLIAM WESTGARTH.

#### APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

JANUARY 27.—“A New Mechanical Furnace, and a Continuous System of Manufacturing Sulphate of Soda.” By JAMES MACTEAR, F.C.S. J. C. STEVENSON, M.P., will preside.

FEBRUARY 24.—“Deep Sea Investigation, and the Apparatus used in it.” By J. G. BUCHANAN, F.R.S.E., F.C.S.

MARCH 24.—“The Future Development of Electrical Appliances.” By Prof. JOHN PERRY.

#### INDIAN SECTION.

Friday evenings, at eight o'clock:—

JANUARY 21.—“Forest Conservancy in India.” By Sir RICHARD TEMPLE, Bart., G.C.S.I.

FEBRUARY 11.—“The Gold Fields of India.” By HYDE CLARKE.

MARCH 4.—“The Results of British Rule in India.” By J. M. MACLEAN.

MARCH 25.—“The Tenure and Cultivation of Land in India.” By Sir GEORGE CAMPBELL, K.C.S.I., M.P.

MAY 13.—“Burmah.” By General Sir ARTHUR PHAYRE, G.C.M.G., K.C.S.I., C.B.

#### CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Second Course will be on “Watchmaking,” by EDWARD RIGG, M.A. Three Lectures.

#### Syllabus of the Course.

##### LECTURE I.—FEBRUARY 7.

Introduction—Units of Time—Historical Sketch—Description of usual forms of watch—Escapements—Conditions of accurate timekeeping, and arrangements necessary for their maintenance in the higher class of watch.

##### LECTURE II.—FEBRUARY 14.

The ordinary watch—Degree of accuracy required in it—Systems of manufacture in this country and abroad—Description of specimens illustrative of the various stages of construction—Comparison of the several systems.

##### LECTURE III.—FEBRUARY 21.

Necessity of efforts to promote the art in this country—Need of education, theoretical and practical, in horology—Literature—Great want of uniformity in gauges, screws, &c.—Exhibition of ordinary and complicated watches, and of watchmakers' tools—Conclusion.

The Lectures will be illustrated by Specimens, Models, and Diagrams. The different movements, &c., will be shown enlarged on the screen by means of the Aphengiscope and the Electric Light.

The Third Course will be on “The Scientific Principles involved in Electric Lighting,” by Prof. W. G. ADAMS, F.R.S. Four Lectures.

March 7, 14, 21, 28.

The Fourth Course will be on “The Art of Lace-making,” by ALAN S. COLE. Three Lectures.

April 25; May 2, 9.

The Fifth Course will be on “Colour Blindness and its Influence upon Various Industries,” by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

May 16, 23, 30.

#### ADMISSION TO MEETINGS.

Members have the right of attending Society's meetings and lectures. Every can admit *two* friends to the Ordinary and Meetings, and *one* friend to the Cantor Books of tickets for the purpose have to be to the Members, but admission can also be on the personal introduction of a Member.

#### MEETINGS FOR THE ENSUING WEEK

MONDAY, JAN. 17TH...Royal Geographical, University, Burlington-gardens, W., 8½ p.m. Mr. C. I. “The Arctic Discoveries along the Coast of Joseph Land, by Mr. B. Leigh Smith, in 1880.” British Architects, 9, Conduit-street, W., 8 p.m. “Journé Discussion on Mr. E. C. Ro “Sanitary Science in its Relation to Civil A Medical, 11, Chandos-street, W., 8½ p.m. Victoria Institute, 7, Adelphi-terrace, W.C. Southall, “Pliocene Man in America,” to be by a second Paper on the same, by Pri Dawson.

London Institution, Finsbury-circus, E.C., W. Huggins, “The Photographic Spectra.”

TUESDAY, JAN. 18TH...Royal Institution, Albemarle 8 p.m. Prof. E. A. Schäfer, “The Blood.” Civil Engineers, 25, Great George-street, S.W., 8 p.m. Messrs. T. F. Brown and G. “Deep Winning of Coal in South Wales.” Statistical, Somerset-house-terrace, Strand, 1 Mr. J. T. Danson, “Growth of the Human Pathological, 53, Berners-street, Oxford-street Zoological, 11, Hanover-square, W., 8½ p.m.

WEDNESDAY, JAN. 19TH...SOCIETY OF ARTS, Adelphi, W.C., 8 p.m. Mr. A. G. Lock Success and Failure in Modern Gold Mining Meteorological, 25, Great George-street, 8 Annual General Meeting. Report of the Address by the President.

Geological, Burlington-house, W., 8 p.m. M. Duncan, “The Coralliferous Series of Connexion with the last Upheaval of the 2. Mr. G. R. Vine, “Further Notes on Diastoporidae, Buak.” 3. Mr. G. W. “Further Notes on the Carboniferous Fer Entomological, 11, Chandos-street, W., 7½ Meeting.

Archaeological Association, 32, Sackville-street, Mr. J. Romilly Allen, “Notes on some Remains near Feating, Forfarshire.”

Institute of Bankers (at the Theatre of the Institution, Finsbury-circus, E.C.), 6 p.m. Chalmers, “The Codification of Mercant especial reference to the Law of Negoti ments.”

THURSDAY, JAN. 20TH...Royal, Burlington-house, W. Antiquaries, Burlington-house, W., 8½ p.m. Linnean, Burlington-house, W., 8 p.m. 1. J. Lowe, “Some Hybrid British Ferns.” 2 Phillips, “A Revision of the genus *Vibris* Chemical, Burlington-house, W., 8 p.m. Armstrong, “Some Hydrocarbons pres Spirit.” 2. Mr. E. Vogel, “Determin Relative Weight of Single Molecules.” : Downes, “The Oxidation of Organic Mat 4. Prof. Liversidge, “Analysis of Queens London Institution, Finsbury-circus, E.C., W. E. Ayrton, “The Production of Elect Royal Institution, Albemarle-street, W., Francis Hueffer, “The Troubadours.” ( Royal Historical, 22, Albemarle-street, W., Numismatic, 4, St. Martin's-place, W., 7 p. Philosophical Club, Willis's-rooms, St. J. 6½ p.m.

Civil and Mechanical Engineers, 7, Westminster S.W., 7 p.m. Mr. J. Coates, “Application Machinery to Mines, Gas Works, Grain &c.”

FRIDAY, JAN. 21ST...SOCIETY OF ARTS, John's W.C., 8 p.m. (Indian Section.) Sir R. “Forest Conservancy in India.” Royal Institution, Albemarle-street, W., 8 Meeting. 9 p.m., Dr. Warren De La Rue ments of the Electric Discharge with 1 of Silver Cells.”

SATURDAY, JAN. 22ND...Physical, Science Schools, St ton, S.W., 3 p.m. Mr. R. T. Glasebrook, ment of Small Resistances.” and “Comparing the Capacities of Two Conden Royal Botanic, Inner-circle, Regent's-park, Royal Institution, Albemarle-street, W., Sidney Colvin, “The Amaryn.” (Lect

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,470. Vol. XXIX.

FRIDAY, JANUARY 21, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.O.*

## NOTICES.

## ADJOURNMENT OF MEETING.

In consequence of the small attendance at the ordinary Meeting, last Wednesday, 19th inst. ; to the inclemency of the weather, the session on Mr. Alfred G. Lock's paper, "Causes of Success and Failure in Modern Gold Mining," adjourned to Monday evening, 24th inst., at 8 o'clock.

Cards of invitation issued for the meeting will be available for next Monday.

## LABEL FOR PLANTS.

The Council are prepared to award a Society's Medal, together with a prize of £5, which may be placed at their disposal for the purpose of awarding to G. F. Wilson, F.R.S., for the best label for plants.

The object of the offer is to obtain a label which is cheap and durable, and may show legibly whether the name is written or printed thereon; the label should be suitable for plants in open border. The following considerations will principally govern the selection.

The award will be made on the recommendation of a committee, which will be appointed for the purpose by the Council.

Specimen labels, bearing a number or motto, accompanied by a sealed envelope containing the name of the sender, must be sent in to the Secretary not later than the 1st May, 1881.

The Council reserve to themselves the right of awarding the Medal and Prize offered, if, in the opinion of the judges, none of the specimens are deserving.

(By order)

H. TRUEMAN WOOD, Secretary.

## PROCEEDINGS OF THE SOCIETY.

## SEVENTH ORDINARY MEETING.

Wednesday, January 19th, 1881; B. FRANCIS COBB, Treasurer of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Barker, George E., Sutherland-villa, Chiswick.  
Barlow, Walter Alfred, 6, St. Paul's-churchyard, E.C.  
Buchan, William Paton, 21, Renfrew-street, Glasgow.  
Burt, Frederick, F.R.G.S., Woodstock, Crescent-road, Crouch-end.

Temple, Sir Richard, Bart., G.C.S.I., C.I.E., D.C.L., The Nash, near Worcester.

Tovey, Major Hamilton, R.E., Waltham Abbey, Essex.

The following candidates were balloted for, and duly elected members of the Society:—

Andrew, Capt. C. W., 286, Kennington-park-rd., S.E.  
Bayliss, Samuel, 5, Victoria-street, Westminster, S.W.  
Browne, Miss Annie Leigh, 58, Porchester-terrace, W. Johore, The Maharaja of, Singapore.

Keymer, H. J. C., Marine-cottage, Gorleston, and Gorleston-docks, Great Yarmouth.

Reid, Arthur G., M.D., Thatched House Club, St. James's-street, S.W.

Rigg, Arthur, 71, Warrington-crescent, Maida-vale, W.  
Taylor, George Noble, 3, Carendon-place, Hyde-pk., W.  
Wiseman, William Percival, Cumberland-house, West Pennard, Glastonbury.

Wragge, Clement Lindley, F.R.G.S., Farley, near Cheadle, Staffordshire, and Adelaide, South Australia.

The Chairman said, as there were so few present owing to the severe weather, it was proposed that the paper should now be read, and the discussion adjourned to Monday next.

The paper read was on—

## CAUSES OF SUCCESS AND FAILURE IN MODERN GOLD MINING.

By Alfred G. Lock, F.R.G.S.

The working of gold mines is usually the earliest and the most rapidly remunerative enterprise developed in the countries where they exist, doubtless from the fact that their produce is unaffected by those conditions which have more or less influence upon almost every other production of nature or art, viz., cost of transport, depreciation by time, and fluctuation of market value. Gold mining is often the first incentive to the occupation of new lands, and has been the primary cause of the progress of our most important colonies.

The "Stock Exchange Year Book" for 1880, reveals the fact that £2,240,449 of English share capital was invested in so-called "gold-mining" enterprises at the end of 1879. An analysis of this sum shows it to be composed of—

£871,658	which has never paid a dividend.
362,041	which has paid none for some years past.
110,000	which is paying about 3 per cent.
896,750	which is paying 10–50 per cent.

£2,240,449

In other words, more than half this large amount is utterly unremunerative. Probably this fact has done much towards creating the popular notion

that gold mining is a very speculative and uncertain enterprise; whereas in fact, none is safer or more highly profitable, when properly conducted. The recent favour shown by the public towards Indian and other gold mines, seems to warrant the selection of the present occasion for a consideration of some of the causes that determine the success or failure of their working. These may be divided at starting into three distinct heads:—

1. The soundness of the constitution of the undertaking.

2. The presence of gold in the property, and the existence of the ordinary facilities for mining operations.

3. The knowledge of how to extract the gold in the property, and the provision of suitable appliances for the purpose.

Given the two first essentials, the problem is to apply the third.

Before proceeding to deal with this question, it will be necessary very briefly to glance at the several conditions under which gold occurs.

#### OCCURRENCE OF GOLD.

These are three—(1.) In the form of scattered grains and nuggets, in alluvial deposits, having been liberated by natural causes from its original matrix; (2.) In the form of grains and leaves, in mineral veins (principally quartz), still enveloped in its matrix, but not associated with any other metals, and technically known as “free” gold; (3.) In the form of grains, imbedded in and most intimately associated with (not chemically combined with) various other metallic compounds, chiefly sulphides and arsenides, and commonly known by the comprehensive term “pyrites,” disseminated throughout veins of quartz or other mineral. The first class I shall pass over, as, though of equal importance with the rest, there is less difficulty and expense in treating it. Our attention will be confined to the free gold and the pyritous gold found in mineral veins.

#### TREATMENT OF THE VEIN-STUFF FOR RENDERING SEPARABLE THE FREE AND PYRITOUS GOLD.

The mere mining operations entailed in obtaining the auriferous rock may be passed over without any discussion, as being thoroughly well understood and carried out. We may proceed at once to the treatment of the material when mined, in discussing which treatment I shall refer, where necessary, to those systems which ought not to be admitted, and shall explain the reasons why they are not admissible.

The first process of the treatment is the disintegration of the material, to such a degree of fineness as will enable the gold and the pyrites to be liberated from the non-auriferous portions of the mass.

*Crushing and Stamping.*—The disintegration of the mineral is conducted in an establishment known as the “reduction works.” The ore, being reduced to a suitable size, is submitted to the pounding action of a series of “stamps.”

These are heavy iron pestles, lifted to a height of some inches, and allowed to fall upon the ore intended to be crushed. They work in a “mortar” or “coffer,” an iron trough, constantly supplied with ore and water, from which the crushed material escapes, as soon as it is reduced to the

desired degree of fineness, through the meshes of closely-fitting screens. The mortar is generally rectangular in form, and contains a set (usually five) of stamps, constituting a “battery.” The mortars should be securely fastened to a solid foundation of heavy timber, so as to prevent jarring when at work. The stamps are established in a substantial framework, and are lifted by means of revolving “cams” or “wipers.” The stamps should be round, never square, and each head should rotate, making part of a revolution each time it is lifted. It was, at one time, objected that the effective capacity of round stamps was less than that of square ones; but it has been proved, by careful experiments under like conditions, that they are equal in that respect, whilst the wear and tear is lessened by the revolution. Their weight and lift, and the speed at which they are driven, vary in almost every reduction works, opinions being greatly divided on each of these points. Their proper adaptation to the ore under treatment has an important influence upon the success of the operation.

The weight of stamps ranges, in Victoria, from 224 to 1,232 lbs. per head. Although a medium weight of 560 to 672 lbs. is found in most instances to best suit the character of the ore, yet, in others, a higher figure may be necessitated. In America, the weight varies from 700 to 950 lbs.

The height of drop or fall varies from 2 to 11 inches in Victoria, and from 7 to 11 inches in America. It should not be less than 7 inches, and may be advantageously increased if the stamps are light.

The speed differs in like manner: in Victoria, it varies from 45 to 85 blows per minute (75 to 80 being generally considered best); in America, from 70 to 100.

The order in which the stamps drop varies in different mills, but the desired conditions are (1), that the work of raising the stamps shall be uniformly distributed on the cam-shaft, so that the weight lifted may be, as nearly as possible, the same at any period of the revolution; and (2), that each stamp shall fall effectively upon the material to be crushed, and maintain its proper distribution. If the stamps were allowed to rise and fall in regular succession, from one end of the battery to the other, the material would accumulate at one end, and the effective duty of all the stamps would be greatly diminished. In a five-stamp battery, a common sequence is (1) the middle stamp, (2) the end one on the right, (3) the second on the left, (4) the second on the right, (5) the end one on the left. Another, which makes a backward and forward wave, and thus keeps the mortar very evenly filled, is (1) the middle stamp, (2) the second on the right, (3) the end one on the right, (4) the second on the left, (5) the end one on the left. In other mills, the end stamps are dropped first, thus, (1) the end stamp on the left, (2) the end one on the right, (3) the second on the left, (4) the second on the right, (5) the middle one. It is thought that the middle stamp dropping first secures the greatest discharge, and that the end stamps dropping first ensures the greatest quantity being stamped.

The action of the stamps in the presence of water is to reduce the material to such a degree of fineness as will enable it to flow off with the water, which flashes up at each blow of the stamps,

through the screens placed at the exit from the mortar. The prompt escape of this fine material is of great importance; consequently, the arrangement should admit of both a back and front discharge. This fact has been overlooked even in some of the batteries most recently despatched to the Indian gold-fields, which were provided with one escape only, and had their effectiveness thus reduced by one-half.

The "gauge," or number of perforations of the gratings, or screens, varies in different works: in Victoria, from 60 up to 800 holes per square inch; in America, from 900 to 10,000 holes per square inch. As this determines the degree of disintegration to which the material is subjected, it should be regulated by the character of the gold contained in the material, and should always be sufficiently fine to ensure the liberation of the auriferous particles. Care must be taken, on the other hand, that it is not so fine as to cause a difficulty in arresting the particles. For reasons to be explained presently, I am of opinion that 400 holes per square inch should not be exceeded.

In order to save the mortars from wear and tear, iron dies, or false bottoms, are placed on them, to receive the blows from the stamps. In America, they are generally of cast iron, and rest directly on the mortar. In Victoria, the much better plan is adopted of allowing the dies to rest upon a layer, at least three inches thick, of finely broken quartz. By having dies of the same size as the stamp-heads placed on this layer of quartz gravel, an opportunity is provided for the liberated gold particles to get into the gravel, out of reach of the stamps, and thence they are easily recovered.

The character of the blow demands attention. The hardness of the mineral containing gold is always so much greater than that of gold itself, or even of auriferous pyrites, that the same amount of stamping on the three substances will render the two latter much finer than the former. But it is of the most importance to prevent the gold from being smashed too fine, or beaten flat, for in those conditions it is very liable to be lost. The tendency of slow heavy blows is to flatten the gold particles, while that of smart light blows is to effect disintegration without materially altering the shape of the particles.

The effectiveness of the stamps is largely dependent upon the regularity with which they are supplied with ore. This is frequently done by hand labour, which has many advocates; but labour is saved, wear and tear are lessened, and usually greater regularity is ensured, by using a self-feeding apparatus. This consists of a hopper, filled with ore, from which an inclined trough leads to the battery; this trough, agitated by the stamps, discharges its contents gradually into the battery.

The trough supplying water to the battery is generally placed under the self-feeding apparatus. The quantity used is in proportion to the character of the ore, and the degree of fineness to which it is crushed. In Victoria, it varies from 30 to 1,200 gallons per stamp-head per hour, though 300 to 500 may be reckoned as satisfying all requirements. In America, on the other hand, about 93 gallons per stamp-head per hour is generally thought sufficient.

It is evident that the weight and speed of the stamps, and the height of their lift, united to the number of holes per square inch in the screens,

chiefly determine the "duty" of the stamps, or the quantity of ore crushed per 24 hours. Accordingly, in Victoria, it varies from 1 ton to 3 tons 13 cwt.: the Port Philip Company's 6-cwt. stamps, giving 75 blows per minute, and requiring 1 h.p. per head, crush an average of 2 tons 4 cwt. each per 24 hours; and their 8-cwt. stamps, making 75 blows, and taking 1½ h.p., average over 3 tons in actual practice. In America, the quantity varies from 1 ton to (in some few instances) as high as 3 tons per 24 hours.

I would here direct attention to a class of stamps recently brought into notice, which, though requiring certain modifications to fit them for gold ore crushing, yet are decidedly a step in the right direction—I refer to W. Rasche's, of Melbourne, "direct acting" battery, Husband's and Sholl's Pneumatic stamps, and Patterson's "Elephant" stamps. They are all based upon one principle: the battery consists of two stamps only, driven at a great speed (150 to 200 blows per minute), and weighing only 2 to 4 cwt. each, their main differences lying in the means adopted for securing the speed. The perfection of stamping, so far as quantity is concerned, would be gained by allowing each stamp in a battery to work independently, and to surround it on all sides by screens. One reason why some of the stamps in Victoria and America crush so much more than others is, that they have screens both at the back and at the front of the battery.

An excellent little stamp for prospecting purposes has been quite lately invented by Dunham. It can be driven by mule or hand power, and is exceedingly portable; the stamp is surrounded by screens, and, consequently, permits the maximum of duty to be reached.

#### APPLIANCES FOR ARRESTING THE GOLD (BOTH FREE AND PYRITOUS) RENDERED SEPARABLE BY THE STAMPING OPERATION.

Having treated of the means by which the auriferous material is disintegrated, it will next be necessary to describe the appliances used for separating the free gold and pyrites from the other finely divided matters, in whose company they leave the battery. This apparatus is effected by a combination of two distinct processes:—(1.) The first consists in directing the components of the mass through, over, or among a body of mercury, which metal possesses the peculiar property of absorbing the particles of free gold. This absorption is known as "amalgamation," and as it constitutes the most certain and satisfactory method of collecting the minute particles of gold from which the mercury can be separated afterwards without loss, the object of all the processes employed is, or should be, to bring the gold into a fit condition to be amalgamated, when it is not already in that condition. (2.) The second process is the provision of a number of checks or obstructions to the onward flow of the matters, with the object of presenting abundant opportunities for the greater specific gravity of the most valuable portions of the mass to exert itself, causing them to be arrested, while the worthless matters and a portion of the pyrites flow away to undergo further treatment.

*Mercury Methods.*—There are three essentially different methods of applying mercury for the re-

covery of the free gold at this stage of the treatment. That most widely used originated in America; it consists in placing a quantity of mercury in the coffer of the stamps, so that it may be pounded up with the material, supplementing this by a considerable area of so-called "amalgamated copper plates," for catching both the free gold which has escaped the mercury and also that which has formed an amalgam with it. The mercury introduced into the batteries is added in small quantities from time to time, according to the richness of the material and the rapidity with which amalgam is formed. The amalgamated plates are formed by a somewhat delicate and tedious process, of covering one side of pieces of sheet copper (more recently electro-silvered) with a coating of mercury. That portion of the interior of the batteries which is not occupied by the screens, is lined with these plates, fixed in an inclined position, and so as to be readily removed and replaced. By the churning that takes place in the battery, particles of gold, mercury, and amalgam are splashed up on these plates, and attach themselves to the surfaces, which are periodically cleaned. Outside the batteries are placed tables, covered with similar amalgamated plates, adjusted at such an inclination as will permit a ready flow of the materials over the surface, without being so rapid as to wash away the gold and amalgam, or prevent their adhesion to the plate. The inclination necessarily differs according to the supply of water, and other conditions. The gold and amalgam collected on these plates are removed in the same way as from the others. The matters not retained by the plates escape with the "tailings," the treatment of which will receive special attention presently.

I venture to assert that this system of putting mercury into the stamp coffers, and using amalgamated plates, is radically wrong. First, as to the former. Even supposing the ore under treatment to contain no pyrites whatever, a condition which is probably never met with in practice, the stamping up of the mercury is alone a cause of great loss of that valuable commodity. But where pyrites is present, there is incurred the additional evil that the pyrites grains form a coating over the globules of mercury and amalgam, or cause "flouring," as it is technically called, thereby producing a triple loss—a loss of gold which has not been amalgamated, of gold which has, and of mercury—for no effective method has yet been found for catching this "floured" stuff. As to the amalgamated plates, it is an incontestible fact that they do not catch such a proportion of the gold as to render them of any real service. Probably the highest portion of the gold caught by them never exceeds 55 per cent.; and when other appliances are not used in conjunction, the loss of gold may amount to half of the total contained in the ore. It may be safely said that their use has been abandoned on all properties where any pretence is made of saving above 80 per cent. of the ascertained contents of the ore.

The second means of exposing mercury to the crushed material may be divided into two heads—mercury "ripples" or "riffles," and mercury "troughs." Mercury ripples consist of grooves cut across the "ripple-board tables," inclined planes of wood, varying in length, and placed in the

route of the materials leaving the stamps. These grooves are cut about 2½ feet apart, and are 1 inch deep at the lower side, diminishing till they are flush with the surface of the bath at the upper edge, and about 3 inches wide. While at work, they are kept nearly full of mercury. They are generally used in combination with blanket-tables, and are most favoured in Australia. The mercury trough may also be considered as essentially Australian. A very effective arrangement of blanket-tables and mercury troughs, adopted by the largest Victorian companies, is as follows:—The material leaving the stamps is led into a trough, having a perforated plate at the bottom to keep back any coarse stuff, by which it is easily distributed; thence it passes into three connected troughs, containing mercury, dropping from the first into the second, and from the second into the third. Each of these troughs is fitted with a splash-board, which, reaching down to within a certain distance of the bottom, compels the falling matter to penetrate the mercury more or less, before escaping over the lip of the trough. Each trough has a tap-hole on one side, by means of which the amalgam may be drawn off. The whole of the contrivance is under lock and key, which prevents stealing. At the end of the blanket-table, another similar trough is placed, through which the material passes before entering the waste-trough. The amalgam formed in all these troughs is periodically removed.

The third plan of amalgamating at this stage is by grinding the crushed material with mercury in little mills, as in Hungary. The same objections apply to this, as to the system of introducing mercury into the material under the stamps.

*Blanket-tables.*—The representative of the second class of appliance is the "blanket-table." This consists of a wooden floor, stretching across in front of the batteries, with a varying length, and laid at a varying pitch or incline. It is fixed securely, and in such a manner as to enable the pitch to be altered, always observing the utmost regularity in its arrangement, and ensuring precisely the same degree of pitch throughout the entire length. The surface of the table is made perfectly smooth and true. By means of narrow strips of wood fastened to the floor, it is subdivided into "strakes," one for each stamp in the battery. Sometimes the table is broken transversely, into sections of three feet or so, the upper edge of each section being about two inches below the over-lapping edge of the next above. The surface is covered throughout with closely woven baize or blanket, laid on with extreme care, so as to lie flat, and cling to the boards.

The mixture of water and disintegrated matters leaving the battery, passes over the surface of the blanketing in a thin stream. The specific gravity of the gold and pyrites causes them to descend to the lowest stratum of this stream, by which they are brought into contact with the fibres of the blanketing, and are induced to settle among them. From these, they are subsequently dislodged by washing in clean water.

Many conditions govern the success or failure of this apparatus. (1.) When the gold is stamped to an excessive degree of fineness, or is flattened into tiny thin plates, it becomes what is known as "float" gold, i.e., owing to the minuteness of the

es, or their flattened shape, they lose the of their great specific gravity, and actually way. Hence the fallacy of too fine stamping. The supply of water, received through the, must be exactly adapted to the nature of material under treatment; if too little, the it will be unevenly distributed, and will blankets; if too great, it will wash away d. (3.) The excessive inclination of the is often a source of great loss; it should y ever be greater than one in 14-16. e length of the table is of importance in re; the inevitable loss to a minimum; for, by far the largest proportion of the valu- matters is deposited on the first few feet of takes, yet, however far the latter may be ned, they will always catch some particles. ctice, it would be inconvenient to much 30 feet, but 20 feet should be regarded as a um figure. (5.) The interstices of the ting would, in course of time, become with heavy matters, and would then cease a receptacle. The renewing and washing therefore, be performed at sufficiently short als. The frequency with which this is ed will much depend upon the character of aterial, being increased when it is "slimy," hen much pyrites is present. The first series ankets may need changing every hour, or oftener, the second every two hours or so, he remainder every six to twelve hours. gold is lost through slovenliness in this de- ent. (6.) Sufficient care is not generally sed in the selection of the fibrous material for covering the strakes; and experi- with various kinds of hair and wool, and different classes of fabric, may be expected to, considerable light upon the subject.

#### TREATMENT OF THE BLANKET-SAND.

*Barrel Amalgamation.*—The material gathered the blanket-strakes, consisting of grains of gold, globules of mercury, and particles of gam, which have been splashed or washed the troughs, ripples, or plates, with a large ity of pyrites and some worthless material, collectively termed "blanket-sand," is usually ed with mercury in a revolving barrel, the as being known as "barrel amalgamation." the proportion of free gold is considerable, the operation is properly conducted, it gives satisfactory results. The barrels are of wood n, and are constructed to revolve on a pivot at end. The charge is 8 to 10 cwt. of the damp et-sand, and 200 to 300 lbs. of mercury; the l is then set to revolve for about eight hours, speed of 14 to 16 revolutions a minute. After it is filled up with hot water, and set to ve again for another four hours, at a rate of 6 revolutions a minute. This concludes the ction, and the charge may be drawn off. The mercury and most of the amalgam are with- n first. The remainder of the contents is to a shaking-table, or some similar contri- for effecting the separation of the amalgam, es, and refuse. The two latter are treated ame as the "tailings." Stones and pieces of are sometimes put into the barrel, with the ous idea that they grind the sand finer, and he amalgamation. This should on no account

be done, as, with pyrites present, the grinding will inevitably cause sickening or flouring of the mercury. When very little free gold is present, it is a better plan to treat the blanket-sand in the same manner as the concentrated tailings, to be described hereafter.

#### TREATMENT OF THE "TAILINGS."

All the stamped material remaining beyond the portions which are caught by the blankets, plates, ripples, and troughs, is collectively known as "tailings." It consists principally of fine earthy matters, but contains also more or less of gold, amalgam, mercury, and pyrites, chiefly the last. In some instances, especially when the ore contains a large proportion of pyrites, the tailings have a very high value; in all cases, the recovery of the gold contained in them demands the earnest attention of the miner who desires to achieve success. Unfortunately their treatment is full of difficulty, and hence the only too frequent disposition to neglect them totally or partially. It is only where the poverty of the ores renders it compulsory to extract all the precious metal they contain, in order to give a remunerative yield, that any really effective and economical plans have been devised for the purpose. Where the ores are sufficiently rich to pay a good profit from the more easily extracted portion, little attention has been given to this question. But the knowledge gained in one region should be applied in all, and there is no excuse for throwing away a quantity of gold because the mine happens to pay well without it. Such an undertaking must be undoubtedly catalogued among the failures, whatever profits it may return.

*Settling-boxes.*—The sands, pyrites, slime and water, which have escaped from the blankets and the last mercury-trough into the waste-trough, pass direct to "settling-boxes," where the current is checked, and the heavier material settles. These boxes are generally cleaned out every few hours, and the material is passed on at once to some machine for concentration. The fallacy of this step will be evident, when we consider that all methods for the mechanical concentration of ores by means of water, based upon the fact that the ore is specifically heavier than the refuse, can only fully succeed when that superior weight of the ore is most thoroughly availed of. I have previously alluded to the fact that the relatively greater specific gravity of the particles may lose its effect in the presence of material of disproportionate size and shape. The latter feature cannot be controlled, as it is determined during the process of crushing; but for the classification of the grains according to size, at least within certain limits, a number of contrivances have been invented, and are in every-day use in Europe, for the concentration of such heavy ores as galena, tin ore, &c. Their value for application to the treatment of auriferous pyrites is intensified by the fact that the gravity of the latter, as compared with that of quartz, presents far less contrast than does that of lead or tin ore to its gangue; besides, the pyrites is so much softer and more brittle than the quartz, that it is crushed relatively much finer. For these reasons, the "sizing" of the tailings, before any attempt is made to concentrate

their valuable portion, must evidently be of considerable advantage.

*Sizing.*—Of the contrivances for classifying according to size, the most exact are probably inclined, rotating, sieve drums. In these, the material is introduced at the higher end, and passes through finer and coarser sieves in succession. But the objection to their use is that they require a considerable amount of attention, so that they are not suited for a country where labour is dear; nor have they the capacity for treating the large bulk of material which accumulates at many of the great gold mines.

The foremost authorities in Australia recommend separation into three sizes, each to be treated distinctly afterwards. Some speak highly of German "pyramidal boxes," and "triangular double troughs." The "pyramidal box" consists of a series of V-shaped troughs, increasing in size towards the outlet, over which a stream of water and material is constantly passed. The heaviest particles fall in the first box, the next heaviest in the second, and so on. The "triangular double trough" has the same object in view. It consists of two or more consecutive V-shaped troughs, into which are fitted triangular stops, which compel the stream of water and material entering at one end to perform a series of descents and ascents. The heavy matters are deposited at the bottom of the trough, while the lighter matters are carried up by the force of the water.

*Concentration or Separation.*—Having classified the material according to size, the next step is to submit each separate size to a process of concentration, with the object of eliminating the valuable portion. For this purpose, many machines are in use. A description of them all would occupy too great space here, but they will receive attention in my forthcoming book. Probably the most perfect, and one which is said by some in Australia to save 95 per cent. of the pyrites present, is Borlase's "buddle," fitted with Munday's "scrapers." It consists of a circular wooden trough, 18 to 24 ft. in diameter and about 1 ft. 6 in. deep. The crushed material, with additional water, is conveyed into a box in the centre of the trough, from which it escapes by revolving pipes, and comes into contact with the sides of the trough. In flowing over the sloping floor of the buddle, the pyrites, from their greater specific gravity, become separated, and are deposited upon the floor, whilst the lighter refuse substances are carried away through a discharge pipe. Several rims or stops are placed on the floor to facilitate the collection of the pyrites, which, as collected, is constantly levelled and distributed by the scrapers, which are set at a suitable angle, and revolve with the shaft. When they descend too deep, owing to the quantity of pyrites collected, they are raised by screws. Attention to the quantity of water and crushed material flowing into the buddle, and the speed at which it revolves, are essential to obtain the best results. The various so-called separators or concentrators, of which I have described one as a type, effect the separation of the pyrites from the gangue or refuse, or, in other words, concentrate the pyrites by elimination of the refuse matters.

#### TREATMENT OF THE PYRITES.

Having secured the pyrites in a fairly clean con-

dition, the next step is to extract the gold contained in them. This is often conducted as a separate industry, especially where the proportion of pyrites yielded by the ores is too small to permit each mine maintaining an establishment for purpose, and where the necessary facilities—of fuel and skilled labour—do not exist.

Under this section, will be included the treatment of all compounds of the baser metals, in which association gold is found. The treatment of ores will have been pretty much the same up to this point, whether the gold were in a free state or associated with various metallic sulphides, arsenides, &c. Of course, should the ore contain no fine gold whatever, the mercury methods might be dispensed with; but the blanket-tables, sieves and concentrators will need more than usual attention.

The gold found in these ores is probably always in a native state, that is to say, it is not in chemical combination, though the mechanical association may be exceedingly close. In some instances indeed, the grains of gold are covered by a microscopically fine film of sulphide, sufficient to prevent actual contact between the gold and mercury. In fact, combined with what has been previously said about the flouring of mercury placed in the blanket boxes, by reason of the sulphides met with, it is conclusively to the error of attempting to separate the gold by amalgamation of the gold in such ores by means of grinding with mercury, for not only will much of the gold be lost, but much mercury will be consumed and also lost.

It may be taken as an established fact that the first step necessary to the recovery of the gold from such compounds is the oxidation of the sulphides, arsenides, or other compounds which hold the gold in solution. The least experienced gold-miner knows that pyrites which has been exposed in heaps for years to the weather, yields a far greater percentage of gold than it did when first placed in a heap, the gold having been liberated by the oxidation caused by the exposure. But this is necessarily a very slow process, and not quite a perfect one. A more rapid and effectual method of securing the same result is by roasting the material in a reverberatory furnace, so as to volatilize the sulphur, &c. These furnaces are constructed on many plans. The one adopted by some of the largest and most advanced works in Australia is the inclined reverberatory furnace of Latta and Thompson. It only requires one man per shift to work it. It consists of a fire-box at the lowest end, from which the heat passes over the pyrites on the hearth. It has doors on each side by means of which the pyrites are gradually drawn down over the hearth, beginning with the hopper which supplies the pyrites, and which is situated at the higher end of it, until they reach the bottom, where they fall into a channel, where they are drawn into a pit. The labour may be reduced by making the furnace in three sections at right angles to each other, so as to facilitate the operation of working the charge through. The roasting must be continued until all the sulphur and arsenic are driven off, and the pyrites become "sweet;" but the heat must not be carried too high, nor is it necessary to convert all the pyrites into sesquioxide. The time occupied in the operation is 12 to 18 hours, but efficiency must not

to time, for partially decomposed pyrites re "flouring" of the mercury, and of gold and amalgam in the succession, than undecomposed pyrites. The is judged by the material emitting nor fumes, by giving off no sparks its turning red when cold, and by run easily when stirred. About of pyrites can be treated in a furnace. The consumption of depend upon the regular feeding of attention must also be paid to the furnace, as it is essential that a air should pass over the surface to ensure their thorough oxidation, must be adopted to effect this, as to whether the presence of a stage of sand with the pyrites is beneficial; on the one side, it is that the sand tends to check the for "caking" of the particles, which, again, makes it very difficult, if not to roast properly; on the other hand, that the sand cuts up the mercury, a great loss in the subsequent process of amalgamation, especially if a Chilean mill is using charcoal with the pyrites in roasting their decomposition by the combination the carbon with the sulphur, but a good properly attended requires no such aid, as lead or antimony are present in the the carbon acts injuriously (by reducing it).

or furnace which is highly spoken of is a revolving furnace. It consists of a fire-box, the heat and products of combustion travel through an iron tube, lined with fire-bricks, supported by a frame which varies with the character of the ore. It rests upon friction wheels, and is rotated by a gear at the lower end; it passes into the upper, and is so arranged as to deliver the ore through it by an opening into the upper. At the upper end, it communicates with a series of condensing chambers. The ore, dried and covered by the condensing chambers, is raised by a hopper by a boy, who also attends to the tube makes three to eight revolutions in its progress, it raises the ore by four shelves parallel with its axis, whence it falls off in thin streams through the heated tube. The sulphur and arsenic thus burn so freely that much of the former, if the latter, will have escaped before the ore has reached half-way along the tube, and the heat by this combustion is available for the upper portion of the tube. The advantages of this furnace are—saving of labour for dressing pyrites, and the completeness with which the distribution is effected.

**Roasting.**—The object of simple roasting is to separate gold from its companionship, and render it amenable to amalgamation. In order to effect this the roasted pyrites are ground with a mill. In Chilean mills, in Arrastras, or in a hopper, or Hepburn and Peterson's pans, &c. in all is to break up the mercury, and to ensure thorough penetration of the sand operated it may take up all the gold brought with it. The successful conduct of this is by no means easy, for the very means

adopted to secure effective amalgamation give rise to a flouring of the mercury, brought about by mechanical action, and causing a great loss of mercury during the subsequent operation of flushing off. Several specifics have been proposed for lessening this loss. "Sodium amalgam" keeps the surface of the mercury bright and quick, owing to the gradual oxidation of the sodium, and is by many considered to prevent flouring, and to assist in collecting the mercury when floured; by others, it is thought to gather base metals, and to cause a loss of mercury. It is probable that more watchfulness and attention to its peculiar properties would make it more generally successful. Solution of soda is useful for freeing the gold particles from grease; the same is more or less true of solution of potash and of lime. Potassium cyanide prevents flouring, and keeps the mercury bright. Of the acids, sulphuric acid acts better than either nitric or hydrochloric.

The matters taken from the amalgamator, of whatever kind, are next passed through a concentrator, or, better, through two in succession, and then through a mercury trough, the tail-sand being run through buddles. The proportion of the gold saved from the pyrites by the proper use of these contrivances has been as high as 95 to 98½ per cent.

Pyrites may consist of the following distinct minerals:—

	Specific gravity.
1. Iron pyrites (mundio).....	4·8 — 5·2
2. Magnetic pyrites (pyrrhotine).....	4·4 — 4·7
3. Arsenical pyrites (mispickel).....	6·0 — 6·4
4. Copper pyrites (chalcocopyrite).....	4·1 — 4·3
5. Sulphide of antimony (stibnite).....	4·5 — 4·6
6. Sulphide of lead (galena).....	7·2 — 7·7
7. Sulphide of zinc (blende).....	3·9 — 4·2

Other rarer compounds are also sometimes found, but only in such small quantities as not to interfere with any process adopted, and they will not be considered in this paper.

The most common form is a mixture of iron, magnetic, arsenical, and copper pyrites, in which any one of these may largely predominate, or be entirely absent. It is usually found that the gold exists in one or two only of the components of the mass, and not in the others. Where the gold is absent from the magnetic and copper pyrites, and present in the iron and arsenical pyrites, these may often be separated by mechanical dressing, based upon the difference in specific gravity. Where this is impossible, and the copper pyrites are sufficiently abundant and valuable to treat, Mr. Cosmo Newbery—who has a great reputation in Victoria—recommends the wet method of copper extraction, leaving the gold to be obtained by the ordinary amalgamation process, instead of smelting.

But it is only within the last few years that any process has been found for extracting the gold from ores containing sulphide of antimony, and many highly auriferous mines in Victoria have been stopped for want of such. In 1873, Messrs. Cosmo Newbery, Ulrich, and Brown, treated antimonial ores by fusing the sulphide with a proportion of metallic antimony, which, having a great affinity for gold, takes it up, and, on cooling, may be easily separated from the sulphide. The antimony is used until it has become rich in gold, when the two metals are separated by the oxidation of

the antimony. But this process is suitable only for ores rich in antimony. Mr. Cosmo Newbery, after long experimenting, has succeeded in discovering a process by which both the gold and the antimony in these poor ores can be saved. His method is to put the ore, as mined, into a close furnace, with some salt or other chloride, and heat it to dull redness; steam is then injected until the whole of the antimony is got rid of. The quartz or gangue is rendered extremely friable, the steam penetrating all parts of even the largest lumps that can be conveniently handled in charging the furnace. The chloride of antimony formed comes into contact with air on leaving the mass of ore, and is converted into oxide, the sulphuretted hydrogen being burnt at the same time; the oxide of antimony is collected in suitable condensers. When the charge is removed from the furnace, it is crushed, and the gold may be saved by amalgamation. The treatment of antimonial sands requires certain modifications. The steam is not easily introduced into a reverberatory furnace without admitting an excess of air, but a close furnace with automatic rakes may be used. The rakes, being perforated, and attached to the steam pipe, are used to distribute the steam in jets through the mass of sand.

Mr. Cosmo Newbery has gone yet further, and has devised in the laboratory a simple and inexpensive method for condensing the solidifiable portions of the fumes. It consists of a small flue, with an artificial draught, produced by a blower. The flue is contracted at intervals to a nozzle, which directs the fumes with force against a fixed plate. It is found that the solid particles adhere to this plate, forming a dense cone of such solidity that the strongest current of air fails to dislodge them.

From the practical results obtained in the treatment of the St. Arnaud (Victoria) ores, which contain, relatively to the gold, large quantities of lead, it would seem that by careful washing after amalgamation in pans, the loss to be feared from its contact with the mercury, may be so reduced as to be scarcely noticeable.

Zinc at a dull red heat alloys with gold, yet the alloy is easily amalgamated by mercury; it therefore requires no special notice.

There remains to consider two processes for the treatment of auriferous pyrites, viz.: Plattner's and Claudet's.

The former was proposed by Prof. Plattner more than 30 years ago, and has been used in Germany and America for many years; in some instances, successfully, in others, not. In Silesia (Germany), ores containing about 9 dwt. of gold per ton have been profitably treated by it; in California, also, it is considerably used. It consists in acting upon the pyrites—after roasting—by chlorine gas, obtained by the reaction of sulphuric acid with peroxide of manganese and salt. The gas forms a chloride of gold, which is dissolved out and precipitated, in the metallic state, by sulphate of iron, or as a sulphide by sulphuretted hydrogen. In theory, it is a simple process, and requires only a few hands; but in practice, there are several drawbacks. Pyrites, roasted and pulverised, fit for amalgamation, would not necessarily be fit for chlorination. Metallic iron must not be present, or it will precipitate the chloride of gold, and

it is essential that all the particles of gold shal as nearly as possible of the same size, as any l pieces will prolong the operation, and so a waste of time and loss. In many countries, it c not be used, as the chlorine-producing mater cannot be obtained sufficiently cheap.

With regard to Claudet's process, Mr. J. Ar Phillips, the well-known metallurgist, who associated with M. Claudet in carrying out invention, assures me that it is quite unfi to deal with ordinary auriferous pyrites, it b essentially a copper process, in which the go obtained as a bye-product at very small pence.

*Oxidation.*—The last point to which I shal is one which bids fair, if successful, to revolue the entire present treatment of pyritous ore is no less than oxidising them before crue thus saving the losses and expenses of conc-tration, roasting, and subsequent amalgam. This, Mr. Cosmo Newbery has successfully a plished in the laboratory, by a similar pro- that I have just described as being used fo treatment of antimonial ores, viz., roasting close furnace with the introduction of steam. remains to be seen whether the cost for fuel, lab &c., will render the operation more profitable t the means now adopted.

#### RESUME.

In this brief description of the processes follow in extracting gold from its natural combinatio I have endeavoured to introduce allusions to the most important of the improper methods wh have crept into use.

A cause of failure not yet noticed is the prac of burning the vein-stuff before crushing, v the object of lessening the wear and tear of machinery, and increasing its effectiveness, rendering the quartz very friable. If pyrites v entirely absent from the ore, the process might valuable; but this is rarely or never the case. simply roasting such large fragments of mint it is impossible to oxidise all the sulphur pre in the pyrites. The result with common i pyrites is that a lower sulphide is formed, w melts, and encloses fine particles of gold i ferruginous glaze; while with arsenical pyr the arsenic set free in vapour may actually form alloy with the gold. In either case, the gol lost.

In conclusion, it may be interesting to illust the consequences of using suitable and unsuit appliances, by a few examples of failure success, quoted from official documents.

First, as to the failures. According to Mr. W. Raymond, there is no subject of "more portance to the mining interest of California t the economical treatment of gold-bearing ores, it is a fact worthy of consideration that, afte years' experience in the business of quartz-min it is conceded that, with a few exceptions, 1 one-third to one-fourth of the assay value of ores now being worked, amounting to sev millions of dollars annually, passes off in slimes, and is irretrievably lost."

In the case of an Australian mine, which abandoned by the owners because they ha knowledge how to extract the gold from the py

lowed gold varying from 19 dwt. 14 gr. 5 dwt. 3 gr. a ton, besides silver, the total being £4 3s. 6d. and £6 1s. 6d. a ton respectively. A sample of what was considered poor gave 9 dwt. 19 gr. of gold and over 25 ozs. The total value being £7 7s. 2d. a ton. A few other samples of tailings, mostly non-collected by the same official, gave the proportions of gold per ton:—9 dwt. 2 dwt. 9 grs., 13 dwt. 17 grs., 16 dwt. 1 dwt. 15 grs., 1 oz. 0 dwt. 21 grs., 1 oz. 1 grs., 1 oz. 6 dwt. 18 grs., 1 oz., 15 dwt. New Zealand, too, no mining company able to pay a dividend from ore having a 10 dwt. of gold per ton, a fact largely positive loss of gold, which, with proper extension indefinitely, but will suffice as illustration. It shows the black side of the case, and would represent gold-mining as a very undesirable and unremunerative undertaking; yet every one of these failures may be directly to a specific fault in the appliances

refreshing to turn to the other side, and see what has been effected by proper plans of treatment.

And here I shall refer only to examples where the amount of gold obtained was less than the smallest amount thrown away in the case, which you will remember was 9 gr. The first and most prominent example well-known Port Philip Co., of Victoria, the managing director, Mr. Rivett Bland, the case of gold-mining is much indebted. This company has to raise its ore from a depth of 700 to 1,000 ft. During the past 10 years, it has treated 1 ton, the average yield of which was 13 gr., the extremes being 3 dwt. 23½ gr. in 1874 and 7 dwt. 21 gr. in 1878. The same company has treated 3,593 tons of pyrites, yielding an average of 4 oz. 3 dwt. 17 gr. of gold, when considered. The average total cost of treatment has been £3 13s. 7d. a ton; the average yield, £13 5s. Another Australian company, the part of its ore from surface workings, probably crushed 283,550 tons, with an average yield of 2 dwt. 22 gr. Another treated 100 tons in seven months, with a return of 10½ gr., and paid £2,101 10s. profit. It realises a large profit from a yield of 1 dwt. 14 gr. per ton of ore crushed. But the most remarkable of all is the Imperial Company at Ballarat, which has treated 2,100 tons of ore, affording only 21·99 gr. of gold per ton, a fair margin of profit on the operation; in other words, it has made money out of material which is only one-tenth part as rich as the non-ferrous material which its neighbours are throwing away.

Now, some allowance must be made for the difference of the ore in different cases, and the conditions surrounding the undertaking; but I do not think any doubt can now remain upon the subject that if the knowledge already acquired in the subject of treating gold-bearing ores were fully and appropriately applied in all cases, we should soon see a satisfactory return for an outlay of one million some odd thousand to which I referred at the beginning of the

## DISCUSSION.

The Chairman said as it was possible there might be some gentlemen present who would not be able to attend on Monday, he should be happy to hear any remarks any one might wish to make.

Mr. J. Valentine Smedley said he should like to express his appreciation of the paper and his thanks to Mr. Lock. He was not a mining engineer, nor qualified to give anything like a technical opinion upon the paper, but as a private individual he was very deeply interested in mining, in spite of himself. He had been connected with mining of various kinds during the last 20 years, as proprietor, as a shareholder in several mines, as director of several collieries, and as chairman, and, from having lost a good deal of money in mining he had endeavoured to abandon it, but in spite of his efforts, somehow or other, mining had stuck to him. At this particular period, when gold mining in India was so prominently before the investing public, Mr. Lock's paper was eminently opportune. The unfortunate experience he (Mr. Smedley) had had in gold mining led him to the conclusion that, whereas, as Mr. Lock had shown, they might be told what methods to avoid, and, on the other hand, what to adopt, he would go farther, and say that even in the case of proper methods and appliances, unless they were properly administered by the local managers or superintendents in charge, the great advantage of the improved methods was lost. It seemed to him that in almost every case the causes of failure had been nothing more nor less than local mismanagement of mines. He had not the number of dividend and non-dividend mines at his finger-ends, but he believed there were more of the latter than of the former; and he was one of those who thought that this was not owing to any want of precious metal in the mines, but because the mines were badly administered. Even in cases where proper treatment, such as suggested by Mr. Lock, had been present, the cause of failure was owing to those methods not being properly administered. He thought the time had come when a revolution must take place in the system of the management of mines.

Mr. Hepple Hall said he had not the same interest in gold mining as the previous speaker, but he had been a great deal in gold mining countries, and had seen a great deal of the various methods adopted. He came there expecting a great treat, and he had not been disappointed, but still he regretted that the paper had not a rather broader scope, for it seemed devoted principally to Australia, with some references to California. He had been in British Columbia and in Nova Scotia, where there was a great deal of gold mining, but this had not been touched upon in the paper. He would withhold any general remarks until the next meeting.

Mr. Fretwell asked if Mr. Lock had had any experience of gold mining in Hungary, especially in Transylvania, and if he could explain why these mines had not been profitable to the Government, who worked them.

The Chairman said Mr. Lock had had considerable experience of Hungarian gold mining, and he would, no doubt, deal with it fully in the discussion. He understood the object of the paper to be on the operations of gold mining, and how to obtain the last grain of gold from the quartz or matrix in which it was contained, but he did not understand that Mr. Lock confined himself to Australia or California. He took those countries as prominent instances of the treatment of gold by crushing, as distinguished from alluvial washing, or anything of that sort. As to the question of the management of gold mines, he hardly thought they could call on Mr. Lock to discriminate between well and ill-managed mines. He simply dealt with the method of treating the ores, with a view to obtaining the best results from them.

Mr. Morgan said he was interested in silver mining and silver extraction, and he should like to ask if Mr. Look had turned his attention to the question of lixiviation. In the concern in America in which he was interested, the rebellious ores were absolutely useless up to a certain time, but by roasting and then treating in a wet way with hypo-sulphite of soda and hypo-sulphite of lime, the mines were now returning very large profits.

Mr. Look said his object was to get the whole subject of gold mining thoroughly considered, and to get everybody to come forward who had something to say upon it. There was a vast outlet for capital in this direction if it were thoroughly understood, but, at the same time, opportunities of learning gold mining in England were wanting, so that the thing could not be properly worked. One gentleman had just mentioned one process, and if the whole subject were gone into and discussed by those who understood it, the discussion would be reported and get to the ears of others, and thus various people would be set thinking upon it, and it might result in the perfection of a new process. It was not fair, therefore, to the subject, to dismiss it in half-an-hour, when there were many anxious to take part in the discussion, who would have attended if the weather had not been so severe. For instance, there was Mr. J. Arthur Phillips, whose view of Claudet's process he had mentioned in the paper. That process was thought a good deal of in Australia, as one which would come largely into use in treating waste tailings, and Mr. Phillips could tell them more about it in five minutes than he could in a week. He should certainly not have given the account he had of it except with Mr. Phillips's express authority.

Mr. Smedley then moved that the discussion be adjourned to Monday evening.

Mr. Hall seconded the motion, which was carried unanimously, and the meeting adjourned.

## CANTOR LECTURES.

### SOME POINTS OF CONTACT BETWEEN THE SCIENTIFIC AND ARTISTIC ASPECTS OF POTTERY AND PORCELAIN.

By Prof. A. H. Church, M.A. Oxon., F.C.S.

LECTURE V.—DELIVERED DECEMBER 20, 1880.

#### *Hard Porcelains, European and Oriental.*

Whatever independent origins in diverse countries may be assigned to terra-cottas, earthenwares, and stonewares, there can be no question that from Chinese porcelain started all attempts to make true china or hard-paste porcelain. Early efforts in this direction failed, for one or other of all of three reasons—ignorance of the materials used in China, ignorance of their local sources, and ignorance of the composition of the paste, glaze, or colours. Difficulties in manipulation and firing there were indeed, but these proved but minor obstacles when knowledge of the materials\* had once been secured. But let me not be misunderstood, for, if the energetic experimenters of the 17th and 18th centuries had succeeded in analysing Oriental porcelain into its constituents—so much silica, so much alumina, so much lime, and so much alkali—they would have been little or no nearer the desired success than before. The qualities or properties which distinguish hard-paste porcelain can be secured only by the asso-

ciation of certain previously formed com Attempts to imitate the body, by heating t proportion of the pure constituent oxides t to the right temperature, have ended in failure. Heat is obviously not the sole f the production of this remarkable mater constituents must be already in some sort s combined before firing, if they are to during that treatment the right condition.

This seems to be the fitting place to intr few words about the minute physical or me structure of hard porcelain. When a thin is examined under the microscope, certain ances are presented with a tolerable appi constancy. We may classify these physic stituents of hard porcelain thus:—

1. Clear paste, the binding material.
2. Opaque rods, called belonites, variou persed and associated.
3. Minute granules, called spherulites.
4. Quartz or other unchanged minerri ments.
5. Spherical bubbles.

It is very common to find three layer ental porcelain (a) body; (b) wash, slip, c ing; (c) glaze. The wash (b) is put on as venient ground for bringing out the colou usually highly aluminous, and so, whi from quartz grains and bubbles, is genera in belonites. These straight-ended, opa are associated in ferruginous porcelains w ous dendritic growths, in which silica is oc with oxide of iron and with lime, as well alumina.

Before entering into details as to the elements of Oriental and European ha porcelains, it will be serviceable if I pri you a series of analyses, some already pu and some new, of porcelain bodies and p clays. On the older analyses implicit relianc be placed. Methods of separation and est were imperfect, and the recognition of m potash, and soda, was frequently most c I begin by drawing your attention to a these older analyses of Chinese porcelain:—

	1st Quality.	2nd Quality.	W
Silica .....	69.0	73.3	
Alumina .....	23.5	19.3	
Oxide of iron .....	1.2	2.0	
Lime .....	.3	.6	
Potash .....	3.3	2.5	
Soda .....	2.9	2.9	

	Dish.	1st Quality.	Int
Silica .....	73.5	71.0	
Alumina .....	18.5	22.5	
Oxide of iron .....	.1	1.0	
Lime .....	trace.	(?)	
Potash .....	5.0	1.2	
Soda .....	(?)	(?)	

I give for comparison with these figu analyses I have made of specimens of ancient porcelain found in a ruined Indian temple

\* On this point, the letters of Père d'Entrecolles, 1712-22, constituted most important sources of information.

	a. White body.	b. Brownish body.	c. Glaze of a.
.....	75.0	72.0	67.5
ina.....	17.8	17.5	14.5
of iron.....	.2	2.5	2.5
.....	1.0	1.5	10.0
.....	4.5	5.0	4.0
.....	1.0	1.0	.5
soda.....	.5	.5	1.0

In looking through these analyses of Chinese kaolin, you will see that the per-centage of silica runs over 71, while that of alumina corresponds to a mean of about 21. Let us keep these in mind when we are examining the composition of hard European porcelains. We may note also the general preponderance of potash soda amongst the alkaline constituents of the ; also the remarkable richness in lime of the example of glaze analysed.

Coming to Japanese porcelain (the manufacture of which probably began about A.D. 1513), I have for you these two analyses by Mr. H.

	Eggshell. Sp. Gr. 2.337.	Thick. Sp. Gr. 2.308.
.....	78.8	74.5
.....	17.8	19.3
le of iron.....	.6	1.9
.....	.2	.1
sh.....	.2	.6
.....	2.0	2.8
soda.....	trace	.2

In these analyses, the chief feature shown is the higher proportion of soda over potash, as to the relative per-centage of these in Chinese porcelains. A detail in the composition of Japanese porcelain may be mentioned, namely, the slight firing which the wares in the biscuit state previous to the firing of underglaze colours and of the glaze; high temperature is used afterwards.

As we gradually accumulating a full series of analyses of Japanese clays, thanks to H. Professor Atkinson, and two other chemists, Würtz found in his examination of Arita that the silica oscillated between 74.5 and alumina between 14.0 and 19.3 per cent. In the analysis the silica was 50, and the alumina as high as 38.7—figures under those deemed by normal kaolin.

Mr. Atkinson's analyses of Japanese clays gave—

	Silica.	Alumina.
uma .. 1 .....	60.7	22.7
.. 2 .....	73.1	20.2
.. 3 .....	59.4	27.9
.. 4 .....	77.2	13.5
.. 5 .....	51.8	30.9

so .. 1 .....	64.7	22.6
.. 2 .....	60.2	23.3
ri .....	54.6	32.4
.. ..	59.1	26.1
to .....	56.9	28.6

If these, it will be noticed, is very near the composition of our European china clays, and some removed from it.

Before speaking of the artistic elements of either Chinese or Japanese porcelain, as illustrated by the specimens on the table, I purpose drawing your attention to that remarkably active period for the European production of hard porcelain, namely, the first half of the 18th century. About the close of the third quarter of the preceding century, Dwight, of Fulham, succeeded in attaining a measure of success, although he had clearly not got hold of the true china clay. But about 35 years afterwards, Bötticher, at Meissen, under the patronage of Augustus II., Elector of Saxony, and King of Poland, first realised in Europe the production of true hard porcelain, equal, if not superior to that of China. It was his knowledge of the proper clay, "Schnorrische weisse Erde," as it is called, found near Aue, Schneeberg, Erzgebirge, which enabled Bötticher to secure success. A chronological list of some of the more important hard porcelain factories, started during the 18th century, presents many features of interest: especially, did time permit, could I show you how the knowledge of the needful materials or ingredients, and where to find them, gradually spread from works to works, generally by workmen who had been discharged, or bribed, had managed to run away with the secret. Thus Vienna got its information from Meissen, Höchst from Vienna, and Berlin from Höchst.

- 1709. Bötticher, at Meissen.
- 1718. Stolzel, at Vienna.
- 1718. Anspach.
- 1720. Bayreuth.
- 1740. Ringler, at Höchst.
- 1744. St. Petersburg.
- 1747. Neudeck.
- 1750. Wegeley, at Berlin.
- 1753. Baden.
- 1758. Ludwigsberg, Nymphenberg, and Fulda.
- 1764. Brancas-Lauraguais at Sèvres.
- 1768. W. Cookworthy, at Plymouth.

Besides all these manufactories of hard paste, many others were established in Germany, France, Switzerland, and Holland, towards the close of the last century.

It will be of interest if I now present you with some analyses of European hard porcelains. We shall be able to discern the chemical differences which sever them from oriental wares; and we shall see that these differences, if they do nothing more, at least give us the means of overthrowing such an egregious fancy as that which has attributed to Lowestoft, in Suffolk, the manufacture of tens of thousands of pieces of inferior Chinese porcelain. Analysis shows at once the absolute identity of duly authenticated pieces of hard Lowestoft, with similar pieces known to have been made in China.

Beginning with Dwight's semi-porcelain made at Fulham, a fragment of an authentic specimen from the Reynolds "collection" gave the following numbers, clearly showing that Dwight had not introduced kaolin into his ware:—

	Per cent.
Silica.....	79.5
Alumina.....	12.5
Oxide of iron.....	1.0
Lime.....	1.5
Potash.....	3.0
Soda.....	1.5

I now give a series of analyses representing the composition of many Continental porcelains:—

	Berlin (1806.)	Berlin.	Meissen (1825.)
Silica .....	66·6	71·3	57·7
Alumina .....	28·0	23·7	36·0
Oxide of iron .....	·7	1·7	·8
Lime .....	·3	·6	·3
Potash .....	3·4	2·0	5·2
Soda .....	(?)	·6	(?)

	Bohemia.	Nymphenburg.	Vienna (1806.)
Silica.....	74·8	72·8	61·5
Alumina .....	21·1	18·4	31·6
Oxide of iron....	(?)	2·5	·8
Lime .....	·6	3·3	1·8
Potash.....	2·5	·6	2·2
Soda.....	·6	1·8	—
Magnesia .....	—	—	1·4

Since the time when hard paste almost, if not quite, completely displaced *pâte tendre* at Sèvres, the composition both of the body and the glaze there has remained constant, except for special purposes. The body is so made up, after analysing the ingredients, as to contain, per 100 parts:—Silica, 58; alumina, 34; lime, 4·5; potash, 3; magnesia and soda, ·5. In order to secure this composition, 73 of kaolin, 24 of felspathic sand, and 3 of lime, were used in 1839. In 1843, the per-centages taken of these three ingredients were respectively 48, 48, and 4. The Sèvres glaze is now obtained with the china-stone of St. Yrieix. Its composition may be gathered from these partial analyses:—

	1826.	1839.	1841.
Silica.....	73·0 ..	73·4 ..	74·3
Alumina ..	16·2 ..	15·7 ..	18·3
Potash ....	8·4 ..	7·4 ..	6·5

It will be remembered that the ascendancy of hard paste at Sèvres dates from 1768. Efforts by the royal factory to buy the secret of kaolin from foreigners had failed, when, as the story goes, Madame Darnet, wife of a surgeon, of St. Yrieix la Perche, found a white clay for cleaning linen in a neighbouring ravine. M. Darnet showed this to M. Villaris, a druggist, of Bordeaux, who recognised in it the long-desired kaolin. He sent the substance to M. Macquer, the chemist of Sèvres, who obtained an identical substance at St. Yrieix in August, 1765, and in June, 1769, read a memoir, illustrated with specimens, on “Porcelaine dure Française.”

A peculiar interest is attached to the excessively rare porcelain made by the Comte de Brancas-Lauraguais. He began, about 1758, discovering the kaolin of Alençon. He worked at Sèvres, and probably also at Chelsea. He was acquainted with the china clay and china stone resources of Cornwall. His English patent, for hard or true china, was taken out in June, 1766, but his invention was never specified. He thus anticipated W. Cookworthy's patent by two years. Brancas-Lauraguais and his porcelain are named in the *Scot's Magazine* for 1764, by Dr. Erasmus Darwin, in a letter to Josiah Wedgwood; and by the

Abbé Raynal. Horace Walpole possessed a certain reproduction, by the Count, of that of Michel Angelo. In M. Gasnault's there is a medallion dated “Octobre, 1768.” The Rouen Museum possesses a specimen of date Septembre, 1768. The Musée de Sèvres has no less than three pieces of Lauraguais porcelain. M. Jules Vallet with coloured decoration in an Oriental style. M. Jacquemart owned a cup. Three specimens in the Alexandra Palace were destroyed in the disastrous fire of 1873. One of these last-named pieces was a tea-poy; its decoration of flowers rendered forcibly of that of Chelsea, period 1760, was fine, hard, and of good colour; another specimen showed to what a degree of perfection the Count had brought his invention. An analysis of a fragment of a twisted piece of this porcelain, with the following results:

	In 100 parts.	
Silica .....	58	} Spec. g.
Alumina .....	36	
Oxide of iron .....	1	
Lime .....	1	
Potash.....	3	
Soda.....	1	

The kaolinic character of this ware is what I have to direct your attention now to. The manufactory of hard paste porcelain in which attained any considerable degree of perfection. We may call it, perhaps, “Plymouth”—company was started in Bristol, as early as 1760, for making china from Cornish mat. The Plymouth factory began in 1768. Champion added the latter to his works in 1773, continuing the manufacture until 1781. No doubt W. Cookworthy had china clay long prior to the earliest of the ceramic chronicles constantly show an interval between china clay and china stone very wide one.

An analysis of Champion's Bristol gave me—

Silica .....	58
Alumina .....	36
Lime .....	1
Potash and soda .....	3

Cookworthy mentions that the kaolin of Stephen's burns, to a degree of transparency without the addition of china stone; but analysis indicates, as we should expect, that china stone was a normal ingredient of his porcelain. Cookworthy used, for glaze, having green spots, from Tregonnin, when he wanted a more fusible mixture of 1 part of lime, and 2 of fern-ashes, to 30 parts of the above china stone. Kaolin, pipe sand were used as safeguards in the kiln.

It will be useful if I now give you a few details about kaolin, although time forbids me to go into full details concerning this substance. Kaolin always completely formed, and derived from the decomposition of the same, it would exhibit a greater constancy of composition and properties than is the case. It is true, a substance of apparent mineral rank has been isolated, and is called kaolinite. But if a substance of this

main constituent (often the chief constituent) china clays, yet the existence of the various kinds of different composition, especially adapted for porcelain-making proved by the analyses of many of the clays used in this manufacture; it must be borne in mind that china is not kaolinite, as it occurs in nature, but free from traces at least of iron, lime, soda, potash, and soda, none of which enter into its composition, but are proofs of the incompleteness of the process by which it has been formed. Indeed, essential constituents may reach a sum of 100 per cent of the total weight of the kaolin. It should be stated, as assumed to possess the following per-centage composition:—Silica, 55; alumina, 39.8; water, 13.9. The greater the water needs a temperature above 212° and so on.

And now direct your attention to the specimens of hard-paste porcelain on the table. A few words seem necessary concerning highly felspathic bodies which come so much into use, that they may well be mentioned. The most notable of these is that of the L. Solon for the decoration of his *décoré* and *sur paille* pieces. Thanks to Messrs. I am able to show you four specimens of refined and lovely work. It is marvellous to see Mr. Solon, as I have been to see him, without outlines or previous laying the wet porcellaneous slip with a brush coloured ware in the green state, and adding the powdery substance into forms of truth and tenderness. If you examine men of this artist's work, this pilgrim's will, I trust, agree with me that the china has yet to be applied, will be very far from the artistic qualities of the surface, the colour, and the design of the piece.

But the manufacturers have their own covering fine work with glass; and the purchasers, for the most part, have no objection to the glazing layer which, if it protects, also and even modifies the body and its colour. Some day, let us hope, a surface like Wedgwood's finest jasper will permit quite work to be thoroughly enjoyed. There are some tiles and a jug, which under the name of "crackle porcelain," have been lent to me. It is a hard, apparently felspathic resembling Wedgwood's jasper bodies, closely in appearance, and in the quality of coloured oxides into intimate union with the mass. From these examples I judge that use may be made of this material for those designs in which softness and richness are desirable without having recourse to

the artist concluded by noticing the chemical characteristics, so far as they threw light on the decorative qualities, of a large number of specimens of Continental and English porcelains, chiefly contributed by Mr. He then examined and explained from a standpoint—crackle porcelain, blue and white Chinese porcelain with black, coloured, and glass, noticing especially the celadon, ruby, and opaque canary and mustard green. He showed how a pure good

cobalt blue is revealed by means of the light from burning magnesium. He spoke also of the various kinds of Oriental white or uncoloured porcelain, and of the methods of decorating it by incised work in the paste. The fertility and skill of the Chinese, as shown in their splashed, mottled, and sprinkled glasses, was touched upon.]

## MISCELLANEOUS.

### CITY OF LONDON COLLEGE.

The prizes and certificates gained by the students at the annual examinations of the City of London College, the Society of Arts, and the Government Department of Science and Art, were distributed on the 4th of January, at the College, in Leadenhall-street, by the Right Hon. A. J. Mundella, M.P., the Lord Mayor being also present. Having distributed the prizes,

Mr. Mundella first directed his remarks to the students, and then addressing the Lord Mayor, observed that it was a matter of great rejoicing to him that the Corporation of the City of London had, during the past few months, made a step in the right direction. They had voted £10,000 towards the new technical guilds to be established at South Kensington, and £2,000 a year for some years, and he saw that the great City guilds, whose names were identified with our British industries, and which had presided over their infancy, but had long ceased to have any connection with them but their name, had recently taken it in hand to improve the skill, industry, and force of the British workman. He, however, thought it was only right to say that the sum which had been raised, £50,000 for building, and £5,000 for sustenance, was altogether inadequate, and if the City of London and the guilds of London were to do anything worthy of their name and position, they must do far more. The sum mentioned was not sufficient for the sustenance of the laboratory. A single institution in a German town had spent £50,000 on the laboratory added to it last year. He knew second and third rate towns spread over the continent of Europe which had spent in the last four or five years double the sum which was supposed to be sufficient to represent the great City of London. The Corporation could do no better work than affiliate this institution to their new college. Mr. Mundella then pointed out what great manufacturers had done for technical instruction in Sheffield, in Leeds, in Dundee, and in Birmingham, and alluded to the noble works done in Manchester and Liverpool; and he urged the merchants of London to follow the example of local towns, and immediately provide a suitable home for the college as good as what the small town of Keighley, in Yorkshire, had done for its locality.

Mr. Henry Cole, in responding for thanks to the Society of Arts, which had helped to give the college its present name in 1853, showed how much the Society had acted as the pioneer of all the existing examinations. Now the great growth of public education had left the Society to examine only in Political Economy and Domestic Economy and Music. To discuss Domestic Economy in education, and show how much it was women's especial work rather than men's, a congress would be held in the summer, when distinguished ladies would be the chief workers at the congress. He congratulated Mr. Mundella on his public declarations to decentralise public education.

Before the meeting ended, the Lord Mayor stated that he would summon a meeting in the City to advocate the claims of the college to have a suitable building, and Mr. Mundella promised to attend it.

## ST. GOTHARD RAILWAY.

An account of the Leggestein spiral tunnel, which is one of the most remarkable works in connection with the St. Gothard Railway, has been communicated to the *Daily News* by the Geneva correspondent of that paper.

"The leading feature of the scheme adopted by the engineers in constructing the line has been to keep to the bottom of the valleys—on the north side of the Alps, the valley of the Reuss; on the south side, that of Ticino—and, so long as they did not deviate too widely from the required direction, to follow their windings until the point fixed for the entrance of the great tunnel should be reached. When this could not be done, and it became necessary to carry the railroad higher, spiral, or to use the German term, 'turn tunnels,' were to be pierced through the mountains. These tunnels made at once a steep gradient and a sharp curve. The gradient of the Leggestein tunnel is 23 in the 1,000, and it describes a curve of 300 metres. After leaving it, the line winds spirally outside the mountain, and passing through a shorter passage higher up, reaches the required altitude. The construction of this tunnel was difficult, less on account of its length, which is nothing extraordinary, than owing to the necessity of boring entirely by hand through a mass of almost impenetrable granite. The progress made at the outset did not exceed three décimètres (twelve inches) in twenty-four hours, even with the aid of blasting. The necessity of handwork arose from the absence of water, and the impossibility, in the circumstances, of using steam for the perforators. Two other turn tunnels—in the valley of the Reuss that of Wellington, 1,000 metres long, and that of Pfaffensburg, 1,000 metres long—will be completed during the coming spring. The former, like the Leggestein, is being bored by hand, the latter by water power. On the south side, in the valley of the Ticino, there are four tunnels (which are to alpine railways what locks are to canals), of from 1,500 to 1,600 metres long, now in course of construction. All these are being bored by water power, and like those on the north side are expected to be finished early in 1881. It is intended to light the great tunnel by electricity. To this end two systems have been proposed. One is to place in the passage 40 electric lamps, each possessing a capacity of 1,200 candles. The interval between each lamp would be about 400 yards, and the necessary motive power would be supplied by the turbines at Airolo and Göschenen, which have been used for moving the perforators and ventilating the workings. The second proposal, whether it be practicable or not, has certainly the merit of greater originality. According to this scheme, a locomotive impelled by compressed air would be stationed at either portal of the tunnel. These locomotives, being smokeless, would be used for drawing the trains through the tunnel. Each locomotive would carry two electric lamps, and two would be placed at the end of the train, together with reflectors, so arranged that their united light would be equal to that of 12,000 candles. By this means, wherever there was a train, and for a considerable distance before and behind it, the tunnel would be brilliantly lighted at a comparatively trifling expense, the electricity being produced and the engines provided with their motive power by the turbines at Göschenen and Airolo."

## CORRESPONDENCE.

## BREAD REFORM.

Dr. J. H. Gilbert, F.R.S., writes to the Secretary of the Society regretting his inability, on account of

pressure of other work, to read a paper at the Society of Arts during this present Session, and goes on to say: "If I had any spare time for such a purpose, I should be disposed to discuss the important food question of the so-called bread reform. Many years ago Mr. Law and myself went somewhat fully into some of the points involved (*Journal of the Chemical Society*, vol. 1, 1857). We showed the distribution of the mineral matter, the phosphoric acid, the different mill products from wheat grain. It is known that about three-fourths only of the total nitrogen in the grain are found in ordinary bread-flour, the remaining one-fourth or so being retained in the excluded portions, which latter are richer in nitrogen than the flour. But it has long been known that a considerable part of the nitrogenous matters of these excluded portions is not in the same condition as those in the flour, and it is stated that they are in an inferior, indigestible and available. Recent investigations show that only from two-thirds to three-fourths exist in albuminoid condition; and it is as yet not known whether, or in what degree, the non-albuminoid nitrogenous bodies are of nutritive value. So far as they are not, the value of the excluded portions is proportionately reduced (so far as this is dependent on the nitrogenous compounds), and it may be even instead of higher, for a given weight, than in the flour. Of the phosphoric acid of the grain, it may be said that not more than about one-third will be found in bread-flour. And, although I am not aware that the point has been proved, it may be that the flour is to a greater degree deficient in a due proportion of phosphoric acid than of nutritive nitrogenous compounds, and, if this be the case, it is a question whether it would not be better to add phosphoric acid in the process of bread-making (as is sometimes done in America) than to include the whole of the more phosphoric portions of the grain. For, if these were supplied in a coarsely-ground state, there would be waste of its passage through the body unused; and, if added as ground as to avoid the aperient action, it is a question whether evil would not then arise from the earthy (and especially magnesia) phosphate, causing irritation and concretion. Indeed, notwithstanding the exclusion of so much of the nitrogen and phosphoric acid of the grain from ordinary bread-flour, we never came to the conclusion that such flour was better than whole-meal bread, for the reasons that the nitrogenous matters of the excluded portions were of nutritive value; that those portions contained a considerable amount of indigestible woody matter; that the branny particles so increased the peristaltic action as to cause the passage from the body of a considerable amount of the food unused. In reference to the whole of the matter which are now again brought so prominently before us, we said, in the paper above referred to (pp. 33, 34):

"The higher per-centage of nitrogen in bran and fine flour has frequently led to the recommendation of the coarser breads as more nutritious than the finer. We have already seen that the more branny portions of the grain also contain a much larger per-centage of mineral matter. . . . It is, however, a very questionable whether, upon such data alone, an opinion can be formed of the comparative value of food, of bread made from the finer or coarser portions of the grain and the same grain. . . . Again, it is an indisputable fact that branny particles, when added to the flour in the degree of imperfect division which our ordinary milling processes leave them in, considerably increase the peristaltic action, and the alimentary canal is cleared much more rapidly of its contents. It is also well known that the poorer classes almost invariably prefer the whiter bread; and among them who work the hardest, and who, consequently, would soonest appreciate a difference in nutritive value (navvies for example), it is distinctly stated that the preference for the whiter bread is founded on the

browner passes through them too rapidly, convey before their systems have extracted from it as nutritious matter as it ought to yield them. It is granted that much useful nutritious matter is, first instance, lost as human food, in the amount of 15 to 20 per cent. of our wheat to the lower animals. It should be remembered, however, that the amount of food so applied means entirely wasted. And further, we know it more than doubtful, even admitting that an equal proportion of mineral and nitrogenous constituents would be an advantage, whether, unless the branny matter could be either excluded, or so reduced as to make the clearing action above alluded to, more than would not be lost to the system by this loss, as would be gained by the introduction into the food, coincidentally with it, of a larger actual amount of supposed nutritious matters. In fact, all experiments tend to show that the state, as well as the chemical composition of our food, must be considered; and words, that its digestibility, and aptitude for assimilation, are not less important qualities than its chemical composition.

Of course, if the branny portions were reduced to the state of fineness, and it were found that this did the aperient action, and that other evils were remedied, or, better still, if more of the food material separated from the bran, and in either case more cost than the saving would be worth, it might be some advantage. But, to suppose that oat meal, as ordinarily prepared, is, as has been assumed, weight for weight, more nutritious than ordinary bread-flour, is an utter fallacy, a theoretical text-book dicta; not only unsupported by experience, but inconsistent with fact, it is just the poorer fed and the harder that should have the ordinary flour bread, and the whole-meal bread as hitherto prepared, the over-fed and the sedentary that should have the whole-meal bread. Lastly, if the whole is on a finely ground, it is by no means certain that the percentage of really nutritive nitrogenous matter would be higher than in ordinary bread-flour, and it is a question whether the excess of earthy matter would not then be injurious." Mr. J. B. Lawes concurs with the opinions stated.

#### EDUCATION CODE REFORM PROSPECTS.

As a member of the Society, to call attention to the prospect of extensive changes in the principles of the Education Code, which is unintelligible except to technical men, like the Education Inspectors and staff at the Department, and not very clear to them. I send extracts from speeches recently made by Mr. Mundella, President, who is reported, on the 1st December, to have said at Huddersfield, "As Vice-President of the Council, he was not disposed to treat the Education Committee as if they were children in leading strings. He wished School Boards to be responsible for the management of the ratepayers and rather less to the Department." On the 15th December, 1880, at Sheffield, he said, "What he wished was responsibility upon the locality and less on the Department;" and on the 29th December, 1880, he said, at the Borough-road College, "The Education Committee desired for the teachers the possible freedom in their teaching, to get away from all unnecessary routine." The Education Committee, on the 31st August, 1879, given in the report, were as follows:—"The schools obtained £6,078 by endowment, £836,792 from rates, £1,249,297 by voluntary contributions, £1,249,297 by endowment, and £23,066 paid by Guardians of the

Poor, making a total of £2,899,366. The Government grant was £1,828,702; all these sums, with £48,841 from other sources, making a total of £4,776,914. Of this the local contributions amounted to £2,948,207, whilst the Government grants were only £1,828,707." Thus it appears that the local funds spent on elementary education were upwards of £1,100,000 more than the Government grant. If Mr. Mundella's excellent intentions are fulfilled, it may be hoped that the present "leading strings" imposed on local authorities will be relaxed in due proportion.

F. S.

#### SIGNALLING BY MEANS OF SOUND.

I was not present when the paper by Mr. Price Edwards, on signalling by means of sound, was read, on the 15th ult., but I have read with interest the report in your *Journal*, and, if permitted, should like to offer a few remarks upon it.

Mr. Price Edwards approves a system of sound signals based on distinctions obtained by making blasts to occur in groups of one, two, three, or four blasts at a time, with varying intervals of half a minute, one, two, or three minutes between the groups of blasts. Sixteen distinct signals are thus obtained.

In the discussion which followed the paper, Mr. Preece supported the proposal made by Sir William Thomson to use a system based on that of telegraphy, using long and short sounds, as in the Morse system, but no one present at the meeting seems to have mentioned the plain numerical system of signals proposed in 1851 by my father, the late Charles Babbage, applicable both to light and sound. It was published in 1851, and was communicated to the Trinity House in November of that year. It was reported on by the Lighthouse Commission of the United States, whose report was printed and published in 1852.

By that system every lighthouse in the world would have its own number, which would be continually repeated, either by light or sound, as long as necessary. Thus, if the lighthouse was numbered 73, there would be during foggy weather seven blasts at short intervals, then a pause; then three blasts, and a longer pause; after which, the same would be repeated as long as the fog lasted. The number of the lighthouse could thus be repeated in less than 30 seconds, and as the lighthouses on either side would be arranged with numbers not having the same digits (say, for example, 25 and 48), the counting of one digit would in most cases indicate the lighthouse, and the counting of the second would afford a check, and give positive assurance of the correctness of the observation, if it was found to tally with the number found on the chart. In this system nothing else has to be done beyond counting the number of the blasts; no previous knowledge whatever is requisite, and a glance at the chart tells everything wanted; surely this is within the intellect of almost any sailor of any nation able to use a chart.

Now, contrast this with the other two systems. In the Morse system, the sailor must observe, not only the length of each and every blast, but he must also watch the sequence of the long and short blasts, and he must know the combinations of them which represent each numeral, before he can be sure of the number of the lighthouse before him, and find it on his chart. It is true that the Morse system is used for the heliograph and army signalling, and also in the Royal Navy for night signalling, but I believe that a specially instructed staff is required in all cases to work it, and that by all others it is found quite impracticable.

In the Trinity House system also, not only must the number of the blasts be counted, but the interval between each group must be measured, and how often would mistakes be made in this during the anxious

moments of danger, when, at any instant, the ship might strike and go to the bottom. Then, supposing the observation correctly made, the mariner would have to search on his chart, not for a simple number alone, but for the comparatively complex characteristics which he has observed, and which would not meet his eye so readily as a simple number; perhaps, if a foreigner, he might not be able to read it at all. Besides these very serious defects, the Trinity House system provides only sixteen signals, of which four only are repeated within the half-minute, and four of them require as much as three minutes; but, in these days of steam, what might not happen from ignorance of the identity of the light-houses for three, two, or even one minute! Then, again, unless the number of the lighthouse was different for light and for sound (which would be very undesirable), restricting the number to sixteen for fog signals, would similarly restrict it for light also.

It seems to me that the simple numerical system has advantages over every other yet proposed, and it is capable of being gradually introduced. Until it has been fairly tried, it should not be rejected by the Trinity House. The expense of setting up one, say somewhere towards the mouth of the Thames, where many could see and hear it, would not be thrown away.

HENRY P. BARRAGE.

Bromley, Kent.

### SANITARY INSPECTION.

There are one or two points in Professor Fleming Jenkin's paper and the discussion upon "A Sanitary Protection Association for London," about which I should like to make a few remarks. The most serious objection to the whole scheme is that, on the face of it, the first expense, namely, the small subscription, is but the prelude to heavier outlay, and that the great majority of persons, whose means would necessitate their taking advantage of the association, could not afford to carry out the works which would be recommended, even if they had a sufficient interest in the property they occupy to justify the expenditure. These would only be dissatisfied with their houses without reasonable opportunity of putting right the imperfections revealed to them, and, in most cases, it would be better for them never to have had a question raised. When anything is radically wrong, the proposed inspection by the association would only lead to the employment of other professional assistance, and no saving would be effected. Again, professors of sanitary matters are so utterly at variance upon what they individually consider to be vital questions, that the public could not place anything like implicit reliance upon the reports furnished them, and would more often than not find those called in to remedy alleged evils disagree altogether with the advice given by the official of the association. Further, there is the difficulty to be encountered with local Boards and Vestries, who often will not sanction what might be considered, from a sanitary point of view, the best modes of dealing with drainage. To illustrate this, I may mention that I am one of those dreadful persons who let land to suburban builders of the speculating class for the erection of small dwellings. Nevertheless, in all cases in which it is reasonably practicable, I should like even these buildings to be constructed on sanitary principles; and with regard to one parcel of ground, my common-sense led me to the opinion stated by Mr. Rawlinson, that "when houses were dealt with as they ought to be, there would be no drain-pipes within them." This piece of ground is surrounded on three sides by roads, in which there is no sewer. This necessitates the construction of a sewer through the middle of the ground, and my desire was to drain all the houses into this through their gardens, and so that no drain-pipes should run under any house. The local authorities, however, would not allow me to

do so, and insisted on the usual drainage through the houses, with regard to those fronting roads having sewers. Consequently, in a row of houses which might have all been drained from the back without any pipes under the house, every alternate house has its drain (carrying its sewerage and that of the adjoining house) running underneath the parlours, with the danger any time of breakage, and the escape of noxious gases, and the unpleasant necessity, in case of stoppage of pipes, of opening up the drain inside the house. There may be some power by which I could have insisted on permission being given to drain in the proper way, but it would not have done for me to have exercised it, being so impolitic to go against local authorities.

I notice, too, that one of the speakers "had strongly for many years the helpless condition in which tenants were placed with regard to these matters." This is to some extent true, though looking at the great number of unlet houses they have to choose from, it is only partially so. But the fact is that the ordinary run tenants do not care, and will not pay for properly constructed houses. A hideous burlesque of grand style architecture, applied to £30 a year houses, will let them readily, though inside they may be, *"whited sepulchres."* Hundreds of assembly-houses stand empty because "they are not profitable enough." Again, the honest builder who spends £300 to £320 in building a £30 a year house, gets on the same rent as the jerry builder, who has constructed houses, similar in appearance, at about two-thirds that cost. The real remedy for the present wretched system of building is a revival of the custom, which have heard used to obtain in town, and largely still in country places, of persons having houses let for them, instead of buying and renting ready-made houses. The question of cost would then be more adjustable to the value obtained.

Finally, let us insist upon cleanliness and order with such means as are at hand. Let closets and drains be frequently flushed and windows opened. In the elementary principles of domestic management now happily being taught to the poorest children in Board schools, be practically applied. In the mean time let professors of sanitation and patentees of sanitary appliances (many of which, let us honestly admit, are good and valuable; but many more of which are absurd and worthless) fight out their wordy strife as they may, and perhaps, even they some day may come to rest upon what are the "principles of sanitation," principles which, up to now, I have vainly endeavored to glean from either their lips or their pens.

JAS. BARRAGE.

East Dulwich, 17th January, 1881.

### NOTES ON BOOKS.

Association Internationale pour l'Eau Potable. 5<sup>e</sup> Générale tenue à Turin le Jeudi, 9 Septembre, 1880, à l'Occasion du Troisième Congrès International d'Hygiène. Amsterdam, 1880.

This volume consists of the address of the President, Mr. J. G. Jager, and the report of the proceedings of the meeting held on the 9th of September. The association grew out of the work of the International Congress of Hygiene, and was formed in Holland with the object of finding an answer to the question put by William III. to his ministers at the period of the cholera epidemic of 1866. The question of the King was this effect—whether the quality of drinking water had any influence over the spread of cholera, and, that influence being admitted, whether the State should intervene, or whether the matter should be left to the com-

urities. After considerable discussion, the unanimously passed a resolution, affirming that necessary for the Central Government to inter-  
 order that the good quality of drinking water  
 assured. Mr. Jäger specially alluded to the  
 of the Select Committee on the Water Supply of  
 the account of which he quoted from the  
 of the Society of Arts.

and Catalogue of Cabinet and Upholstery  
 clare, Looking-glasses, &c. London: C. and R.  
 M. Curtain-road, 1880.

large folio volume contains one thousand nine  
 and eighty designs for articles of furniture  
 variety of styles, which are arranged under  
 of hall, library, dining room and parlour,  
 room, bedroom, camp and ship, kitchen, and  
 . The information given in this book is so  
 as to be practically useful to those who  
 designs for furniture, such as are called for  
 wants of the present day. Prefixed are  
 notes on Household Furniture," which con-  
 tain sketch of the changes that have taken  
 the fashion of British furniture from the  
 the Saxons, when little more was found  
 than a series of benches and a heavy table  
 h the dwellers in the house and the guests  
 ght, down to the present time when furniture  
 s Early English, Mediæval Gothic, Renaiss-  
 an, Venetian, Louis XIV., Louis XVI,  
 e, Chippendale, Neo-Greek, and Japanese,  
 air different admirers. Special mention is  
 r William Chambers, the architect, Thomas  
 s and Thomas Sheraton, the cabinet-makers,  
 s Hope, the connoisseur, whose works greatly  
 the fashion of domestic furniture in Eng-  
 ppendale's "Gentleman and Cabinet-maker's  
 was published in the year 1759, and  
 have suffered from some adverse criticism.  
 ty of the designs are of that pure and rather  
 e which is associated with his name, but  
 also specimens of florid ornamentation in the  
 much taste adapted to frames and cornices  
 ously enough are now often referred to as  
 Chippendale work. Sheraton's "Cabinet-  
 Upholsterers' Drawing Book" appeared in  
 ret volume being devoted to the science, and the  
 the art of the cabinet-maker's trade. Mr.  
 me, entitled "Household Furniture and In-  
 nation," was published in 1807, and contained  
 nber of designs in a purely classical style. His  
 t in directing attention to this subject was  
 furniture which should harmonise with the  
 us collection of antiquities. The critics,  
 ord Jeffrey of the *Edinburgh Review*, laughed  
 or, but in spite of opposition the book exerted  
 ide influence. The introduction to Messrs.  
 ook also contains some remarks upon the  
 the several articles of furniture appropriate  
 ons rooms.

## GENERAL NOTES.

ological Museum at Sidney.—A Technological,  
 and Sanitary Museum for New South Wales is  
 sed at Sidney. This museum is intended to  
 similar position and fulfil the same purpose in that  
 as South Kensington Museum, the Bethnal-green  
 the Museum of Practical Geology, the Patent-  
 um, and the Parkes Museum of Hygiene do in  
 To this end, it is intended to collect together  
 sections of all materials of economic value belong-

ing to the animal, vegetable, and mineral kingdoms, from  
 the raw material through the various stages of manufacture,  
 to the final product or finished article ready for use. The  
 following are the chief subjects which will be represented:—  
 1. Animal products. 2. Vegetable products. 3. Waste  
 products. 4. Foods, animal and vegetable. 5. Economic  
 entomology. 6. Economic geological specimens, showing  
 the ores of the metals, their manufacture and uses; building  
 and ornamental stones, clays, cements, glass, pottery,  
 porcelain, pigments, &c. 7. Educational apparatus and  
 appliances, school fittings, books, maps, diagrams, &c.  
 8. Sanitary and hygienic appliances and systems. 9. Mining,  
 engineering, and machinery. 10. Agricultural tools,  
 appliances, and machinery; also soils, manures, &c.  
 11. Models, drawings, and descriptions of patents.  
 12. Ethnological specimens. 13. Examples of historical  
 furniture and of artistic workmanship in iron and other  
 metals. 14. Photographs, electrotype, plaster, and other  
 reproductions of examples of art workmanship where  
 originals are not to be obtained. 15. Exhibition catalogues,  
 trade journals, price lists, and descriptions of new processes  
 or industries. The acting-secretary, Mr. Charles R. Buck-  
 land, asks for contributions to the museum.

## MEETINGS OF THE SOCIETY.

### ADJOURNED MEETING.

Monday evening, at eight o'clock:—

JANUARY 24.—Discussion on Mr. A. G. Look's  
 paper, "Causes of Success and Failure in Modern  
 Gold Mining." HYDE CLARKE, Esq., will preside.

### ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

JANUARY 26.—"Suggestions for Preventing London  
 Smoke." By W. D. SCOTT-MONCRIEFF.

FEBRUARY 2.—"Trade Prospects." By STEPHEN  
 BOURNE.

FEBRUARY 9.—"The Present Condition of the Art of  
 Wood-carving in England." By J. HUNGERFORD  
 POLLEN. Sir PHILIP CUNLIFFE OWEN, C.B., K.C.S.I.,  
 will preside.

FEBRUARY 16.—"The Participation of Labour in the  
 Profits of Enterprise." By SEDLEY TAYLOR, M.A.,  
 late Fellow of Trinity College, Cambridge.

FEBRUARY 23.—

MARCH 2.—"Flashing Signals for Lighthouses."  
 By Sir WILLIAM THOMSON, LL.D., F.R.S.

MARCH 9.—"Improvements in the Treatment of  
 Esparto for the Manufacture of Paper." By WILLIAM  
 ARNOT, F.C.S.

MARCH 16.—"The Manufacture of Aerated Waters."  
 By T. P. BRUCE WARREN.

MARCH 23.—"The Increasing Number of Deaths from  
 Explosions, with an Examination of the Causes" By  
 CORNELIUS WALFORD.

MARCH 30.—"Recent Advances in Electric Light-  
 ing." By W. H. PREECE, Pres. Soc. Tel. Eng.

Dates not yet fixed:—

"Buying and Selling; its Nature and its Tools."  
 By Prof. BONAMY PRICE. On this evening Lord ALFRED  
 S. CHURCHILL will preside.

"The Discrimination and Artistic Use of Precious  
 Stones." By Prof. A. H. CHURCH, F.C.S.

"The Compound Air Engine." By Col. F. BEAUFORT,  
 R.E.

## FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

FEBRUARY 1.—"The Industrial Products of South  
 Africa." By the Right Honourable Sir HENRY BARTLE

FRERE, Bart., G.C.B., G.C.S.I., D.C.L., LL.D. Sir RICHARD TEMPLE, Bart., G.C.S.I., C.I.E., D.C.L., will preside.

FEBRUARY 22.—"The Languages of South Africa." By ROBERT N. CUST.

MARCH 15.—"The Loo Choo Islands." By Consul JOHN A. GUBBINS.

APRIL 5.—"Trade Relations between Great Britain and her Dependencies." By WILLIAM WESTGARTH.

#### APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

JANUARY 27.—"A New Mechanical Furnace, and a Continuous System of Manufacturing Sulphate of Soda." By JAMES MACLEAN, F.C.S. J. C. STEVENSON, M.P., will preside.

FEBRUARY 24.—"Deep Sea Investigation. and the Apparatus used in it." By J. G. BUCHANAN, F.R.S.E., F.C.S.

MARCH 24.—"The Future Development of Electrical Appliances." By Prof. JOHN PERRY.

#### INDIAN SECTION.

Friday evenings, at eight o'clock:—

JANUARY 21.—"Forest Conservancy in India." By Sir RICHARD TEMPLE, Bart., G.C.S.I., C.I.E., D.C.L. ANDREW CASSELS, Member of Council, will preside.

FEBRUARY 11.—"The Gold Fields of India." By HYDE CLARKE.

MARCH 4.—"The Results of British Rule in India." By J. M. MACLEAN.

MARCH 25.—"The Tenure and Cultivation of Land in India." By Sir GEORGE CAMPBELL, K.C.S.I., M.P.

MAY 13.—"Burmah." By General Sir ARTHUR PHAYRE, G.C.M.G., K.C.S.I., C.B.

#### CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Second Course will be on "Watchmaking," by EDWARD RIGG, M.A. Three Lectures.

#### Syllabus of the Course.

##### LECTURE I.—FEBRUARY 7.

Introduction—Units of Time—Historical Sketch—Description of usual forms of watch—Escapements—Conditions of accurate timekeeping, and arrangements necessary for their maintenance in the higher class of watch.

##### LECTURE II.—FEBRUARY 14.

The ordinary watch—Degree of accuracy required in it—Systems of manufacture in this country and abroad—Description of specimens illustrative of the various stages of construction—Comparison of the several systems.

##### LECTURE III.—FEBRUARY 21.

Necessity of efforts to promote the art in this country—Need of education, theoretical and practical, in horology—Literature—Great want of uniformity in gauges, screws, &c.—Exhibition of ordinary and complicated watches, and of watchmakers' tools—Conclusion.

The Lectures will be illustrated by Specimens, Models, and Diagrams. The different movements, &c., will be shown enlarged on the screen by means of the Aphenioscope and the Electric Light.

The Third Course will be on "The Scientific Principles involved in Electric Lighting," by Prof. W. G. ADAMS, F.R.S. Four Lectures.

March 7, 14, 21, 28.

The Fourth Course will be on "The A making," by ALAN S. COLE. Three Lectures.

April 25; May 2, 9.

The Fifth Course will be on "Colour and its Influence upon Various Industries," by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

May 16, 23, 30.

#### ADMISSION TO MEETINGS.

Members have the right of attending Society's meetings and lectures. Everyone can admit two friends to the Ordinary and Meetings, and one friend to the Cantor Books of tickets for the purpose have to the Members, but admission can also be on the personal introduction of a Member.

#### MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 24TH...SOCIETY OF ARTS, John-street, W.C., 8 p.m. Adjourned discussion: Lock's paper, "Causes of Success and Modern Gold Mining." Royal United Service Institute, Whitehall: Capt. L. K. Scott, "Suggestions for Improving Artillery Fire, combined with an E. Capt. Scott's system of Sighting Gun illustrated by models." Medical, 11, Chandos-street, W., 8½ p.m. Royal Asiatic, 22, Albemarle-street, W., 3 p.m. London Institution, Finsbury-circus, E.C., E. B. Tylor, "Problems in the History of

TUESDAY, JAN. 25TH...Royal Institution, Albemarle-street, W., 8 p.m. Prof. E. A. Schäfer, "The Blood." Medical and Chirurgical, 53, Berners-street, W., 8½ p.m. Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on "Deep Water in South Wales." Anthropological Institute, 4, St. Martin's-street, W., 8 p.m. Annual Meeting. Royal Colonial, the Grosvenor Gallery Library, Bond-street, W., 8 p.m. Sir Alexander's Future of Canada."

WEDNESDAY, JAN. 26TH...SOCIETY OF ARTS, Adelphi, W.C., 8 p.m. Mr. W. D. Scott, "Suggestions for Preventing London Street Telegraph Engineers and Electricians, 4, Bir S.W. 1. Inaugural Address by the Pres. C. Foster. 2. "Mr. W. Heavinside, 'ments on Induction with the Telephone.' Royal Society of Literature, 4, St. Martin's-street, W., 8 p.m. Mr. Robert N. Cust, "A Recent with Notices of the Al Hamra and of Spain."

THURSDAY, JAN. 27TH...SOCIETY OF ARTS, Adelphi, W.C., 8 p.m. (Chemical Section) Maclean, "A New Mechanical Furnace: Continuous System of Manufacturing Sulphate of Soda." Royal, Burlington-house, W., 4½ p.m. Antiquaries, Burlington-house, W., 8½ p.m. London Institution, Finsbury-circus, E.C., H. E. Armstrong, "The Manufacture of Coal." Royal Institution, Albemarle-street, W., Francis Hueffer, "The Troubadours." Inventors' Institute, 4, St. Martin's-place, Royal Society Club, Willis's-rooms, St. J. 6 p.m.

FRIDAY, JAN. 28TH...Royal United Service Institute, Whitehall, 8 p.m. Colonel Thomas Innes, "The Militia." Royal Institution, Albemarle-street, W., Arthur Schuster, "The Teachings of Spectroscopy." Quakett Microscopical Club, University College, 1, Mr. B. W. Priest, "Sponges." Cobbold, "Filaria." Clinical, 22, Berners-street, W., 8½ p.m. AN SATURDAY, JAN. 29TH...Royal Institution, Albemarle-street, W., 8 p.m. Prof. Sidney Colvin, "The (Lecture II.)"

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,471. Vol. XXIX.

FRIDAY, JANUARY 28, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## HOUSE SANITATION.

The Council offer the following Medals for showing the best Sanitary Arrangements as built in the Metropolis, such plans to be submitted in the Society's Rooms, Adelphi, in 81, and to be sent in on or before 12th 31:—

1. Silver Medal for the best sanitary arrangements carried out and in satisfactory working, and let out in tenements to artisans, for weekly rental is paid.

2. Silver Medal for the best sanitary arrangements, in actual working, in a house of the rental of £40, or less, to about £100 in value.

3. Silver Medal for the best sanitary arrangements, in actual satisfactory working, in a house the yearly rental value of £200 and upwards of any amount.

4. Houses must be open to the inspection of judges, who, in considering their award, guided by the suggestions of plans for sewerage, drainage, and water supply, made under the Public Health Act, 1875.\* The houses must have been in actual occupation within the last six months, and a Certificate must be given by the occupiers, on a printed form, stating the satisfactory working of all the sanitary arrangements. The form to be obtained at the Society of

Artists. Houses may be old, fitted with modern sanitary arrangements, or may be new. They must be within the metropolitan area of the Board of Health.

5. Sanitary arrangements must include the arrangements for good water supply, drainage, warm-ventilation of the house, and precautions against frost.

6. Medals may be awarded to the occupiers, tenants, or the lessees, or the owners.

\* The Health Act has been revised to 1878, and published by the Stationery Office. Price, with plans, three

8. The plans must consist of a ground plan and sections, to the scale of not less than one inch to five feet; details of not less than one inch to the foot. The plans may be accompanied by specifications.

9. The names of the architects, surveyors, or sanitary engineers who directed the sanitary arrangements should be given, and Certificates will be awarded to those whose plans obtain the Medals.

(By Order)

H. TRUEMAN WOOD, Secretary.

## DOMESTIC ECONOMY.

1. The Council will hold a Third Congress on Domestic Economy, at the Society's Rooms in the Adelphi, London, during the present year.

2. The Council offer Seven Bronze Medals, and Certificates of Merit for Papers (not exceeding 1,000 words), written by Teachers of Public Elementary Schools and Training Colleges, which shall give an account of the best method practised by the teacher, of the teacher's experience, and the result of the teaching, in any one or more of the seven classes of subjects named below.

3. The Education Department, in the Code of 1880 (p. 31), classes the following subjects under Domestic Economy for Girls:—

The First Branch includes—

- (a) Clothing and Washing.
- (b) The Dwelling—Warming, Cleaning, and Ventilation.
- (c) Rules for Health—The Management of the Sick Room, Cottage Income, Expenditure, and Savings.

The Second Branch includes—

- (a) Food—Its Composition and its Nutritive Value
- (b) Food—Its Functions.
- (c) Food—Its Preparation and Culinary Treatment (i.e., Practical Cookery) (§ 24).

The Council have resolved to add the subject of Needlework, which will be exhibited and discussed in the Congress, although it is not classed in the Code as a branch of Domestic Economy.

4. Only one medal will be given to a teacher, but the subjects taught successfully will be inscribed on the one medal and a certificate given.

5. The papers must be sent to the Secretary of the Society of Arts by the 1st May next. Each paper must be enclosed in a sealed envelope, bearing a motto, and must be accompanied by an envelope bearing the same motto, and having within it the writer's name and address.

6. No medals or certificates will be awarded if the papers are not of sufficient merit to deserve them.

(By order)

H. TRUEMAN WOOD, Secretary.

### EXAMINATIONS IN PRACTICAL MUSIC.

The following report on these examinations has been received from Dr. Hullah :—

The Society of Arts' Examinations in Musical Practice were held at the Society's House and (by the kind permission of Messrs. Chappell) at 50, New Bond-street, on the 10th and 11th inst. In the conduct of these, I was assisted by Mr. W. A. Barrett, Mus. Bac. Oxon., who had kindly taken the sole charge of them on the only occasions on which they had before been held, from both of which I had, unfortunately, been absent.

For these last examinations, 75 names had been entered, the owners of three of which did not present themselves. To the remaining 72, we had the pleasure of awarding 42 certificates of the first class, and 33 of the second. The maximum of marks assigned to the candidates is 100, of which 80 are needed for the attainment of a first-class certificate and 60 for a second. Of the former candidates, two attained the maximum number of marks, 100.

The majority of the candidates (63) were students of the pianoforte (59) or organ (4); (2) of the violin; and (23) vocalists. Of these 11 went in both as vocalists and pianists. Of four of these candidates, who also went in for "Honours," two attained first-class certificates, and one a second-class certificate.

Such a result as this demands a few words of comment, as well as of congratulation both to those who have instituted these and similar examinations as to those who have gone through them successfully. Though only in their second year, these practical examinations are an outcome of the examinations in the theory of music started by the Society of Arts in 1859; and, like those, are an evidence of the progress which musical science and skill have made in this country during the last twenty years. My own experience of them is of long date; and I have no hesitation in saying that they mark an amount of progress in execution, style, ear, reading, and general musical culture no parallel to which, in the same space of time, has been presented in any other age or country.

JOHN HULLAH.

London, Jan. 19, 1881.

### INDIAN SECTION.

Friday, January 21st; ANDREW CASSELS, Member of Council, in the chair.

The Chairman, in introducing Sir Richard Temple, said he considered himself fortunate, on this opening night of the Indian Section, in being permitted to introduce so distinguished an Anglo-Indian as Sir Richard Temple. To those who were at all acquainted with India, his name must be as familiar as a household word. Few Englishmen, or natives either, had ever seen so much of India as he had, having traversed it in all directions. He had served the State in different capacities, with advantage to his Government and credit to himself. As he had the honour of being chairman of the Indian Section for the present year, it might not be improper for him to state, on this opening night, that one of the rules of the Society was, that all political topics should be avoided. He did not say this in reference to that evening's discussion particularly, but in reference to any papers which might come before the

Society. If it were otherwise, as a member of the Council of India, he could scarcely hold the position he had the honour to occupy.

The address was on—

### FOREST CONSERVANCY IN INDIA.

By Sir Richard Temple, Bart., G.C.S.I., C.I.E., D.S.I.

I am about to offer to you, not a lecture, but an oral address in a conversational style, if you will allow me. I must, in the first place, thank those who are present here for coming to this meeting on such a night, and in such inclement weather, but we shall have a larger audience of several thousand members of the Society outside, who will read the report of our proceedings in the *Journal* of the Society. I may say that I esteem it a great honour to be asked to deliver an address before the Society of Arts, remembering as I do, in common with all Englishmen, the great historical and distinguished part which the Society of Arts has played in the educational and industrial history of England during the 19th century. Not only has the Society done much for fine arts, of which we see traces in the room in which we are assembled, but more especially has it done great things in the application of science to all the varied industries of England. It has also done more, probably, than any other Corporation in England, for the advancement of technical education; and in the remarks I shall make to you regarding forests, you will find a signal proof of the mischief which has been wrought, mainly, from the want of technical and professional knowledge on the part of our own countrymen in India regarding forestry. I feel, however, much encouragement in addressing you this evening, when I look back on the names of the great men who have guided the deliberations of this Society, such men as the Duke of Norfolk in the last century, H.R.H. the Duke of Sussex, H.R.H. Prince Albert, and now H.R.H. the Prince of Wales. We have also had and have now on the Council of the Society men whose names are really the property of the nation, such men as Wentworth Dilke, Lubbock, Leighton, and Galton. But more especially we have had on the Council many men who have contributed much to develop the industries of India in particular, such men as Cole, Sykes, Birdwood, Alcock, Siemens, Cunliffe-Owen, and Brassey. Well then, looking to these names of men, some departed, and others still present among us, we ought all of us, those who speak and those who listen, to feel the responsibility which attaches to all of us in assisting in the deliberations and proceedings of such a Society as the Society of Arts. Amongst its many educational and scientific operations, arboriculture was one of the earliest. As a remarkable instance, I may remind you that it is now nearly 130 years since this Society began to pay attention to forestry, an attention which, as you perceive, remains undiminished up to the present moment. It was soon after 1760, as you will perceive from the history of London, written by Charles Knight, and Davenport's history of our Society, that gold and silver medals, presented by this Society for planting fir and cedars, were won by such distinguished persons as the Dukes of Bedford and Beaufort,

l Paget, Earls Winterton, Ossory, Mansfield, Wilton, the Bishop of Llandaff, and the Duke of Tichfield. There were also men in days whose names have been handed down in history of British agriculture as well as in horticulture, namely, Curwen, of Windermere, and John Hutton, of Yorkshire, and Buck-

These men originally showed what could be in the way of tree plantation in Great Britain, it is to be hoped that they may prove to be ancestors of a long line of Englishmen, who, generation to generation, will distinguish themselves in arboriculture in all parts of the British Empire throughout the world.

In this brief preface, which I hope will not be uninteresting to members of the Society at present time, I will pass straight to the subject of the evening, namely, "Forest Conscience in British India." India, of course, is the only country in which questions regarding forestry are becoming prominent. The mischief which has been wrought by the destruction of forests is patent on the face of Europe. Destructive floods which have occurred in various parts of France, are directly due to the denudation of the Swiss hills. Similar questions are being raised in South Africa, and we hear even injury being feared in the United States of America. In India, the destruction has been vast. Traditions of the forests in India show how the land was once clothed with sylvan and other vegetation.

But every time a city had to be built or a temple erected, or in modern times a railway to be constructed or barracks to be built, there has been a ruthless destruction of forests. Of course the forests were made for the use of man, but they may be so cut as to leave something for reforestation. Instead of that "they have been swept away as clean as if they had been shaven by a razor" speak figuratively. Well, notwithstanding this destruction, still forests remain, though they can hardly be said to be more than the remnants of what once were the forests of India. You will say, perhaps, why did not the Government and its officers prevent this devastation. They did not stop it, simply because they were none of them properly instructed in matters regarding forests. Such ignorance is to be wondered at, considering the ignorance which has prevailed in Europe and in other parts of the world. I know that 20 or 30 years ago, when we were young men in India, we, none of us, had of any principles regarding the forest conscience. The consequence was that forests, being remote and difficult of access, not easy to visit or understand, and we ourselves being ignorant of anything regarding forestry, we paid no attention whatever to the subject, and consequently, when wood was wanted, forests were cut down by persons who had nothing to do except to make as much as they could at the present moment, without regard to the future, and so forests have been destroyed in the most thoughtless and merciless manner. Still, there are great mountain ranges, for instance, the Western Ghats, which form a continuous wall on the western coast; the Eastern Ghats, which form a similar range, although so regular, on the eastern coast; two great ones, the Satpura and Vindhya, which unite in the direction of Bengal, and form one broad mountainous region; there are the mountain ranges on

the east of Bengal, separating Bengal from Burmah; and, lastly, there is the great Himalaya range itself. I do not now speak of the mountain range on the west of the Indus, because that was originally a region mainly destitute of vegetation, and whatever vegetation there was has long been swept away by the action of man; so that really the great range which separates India from Afghanistan counts for nothing, in the language of forestry. The ranges with which forestry in India has to do are the Western Ghats, the Eastern Ghats, the Satpuras and Vindhya, the Eastern Bengal ranges, and the mighty Himalayas.

In these mountain ranges, there are numerous kinds of trees, which constitute a forest flora in themselves. It is quite impossible for me, within the time at our disposal, to even enumerate, much less describe to you, the various kinds of trees which exist in the Indian forests; still I may mention, by way of recapitulation, some of the most striking and interesting trees which we have. The trees of India must be divided mainly into two main divisions, the Himalayan division, and the plain division, which latter comprises the whole of India proper.

Now, the Himalayan trees are allied mainly to the trees of Europe and other temperate regions. The *coniferae*, including the great genera of firs, pines, and the like, are found all over the Himalayas. Amongst them the queen is the cedar. Nowhere in the world are such fine cedar forests to be seen as are in the Himalayas. You have some idea, in this country, from the lawns of our principal country seats, of what beautiful shape and colour the foliage of the cedar is; then imagine trees much grander, much finer in trunk, and branch, and foliage, with a background of everlasting snow; imagine them situated in the midst of rugged situations, and with the most glorious surroundings. And there is a further interest attaching to them, from the way in which they are felled, and the mode in which the logs, when felled, are transported to market. The value of a cedar forest depends on its situation. If the trees stand upon precipitous sites, overhanging rivers, they are felled to great advantage. The tree is felled, and the log is shot down the precipice into the roaring, cataract-like, torrent of the river. The river itself acts as a carrier, and whirls log after log down to the plains. And as the river, laden with all this freight of cedar logs, emerges from the Himalayas, skilful native swimmers are stationed on the bank, and dart forth and catch the logs as they descend the stream.

Similar remarks apply to the *Pinus longifolia*, which is, next after the cedar, the most valuable timber tree in the Himalayas. In fact, in Northern India, most of the great public buildings of the British Government, and most of the palaces of the native princes, are largely constructed with the timber of cedar and pine. As a matter of interest, I should not omit to mention the cypress. But the cypress of the Himalayas is not the funereal sort of tree which you read of, or see depicted, as constituting a great feature in the cemeteries and burial-grounds of the Levant or Constantinople, but is a truly magnificent tree, growing, too, in the very midst of the limestone formations. There appear to be certain chemical elements in the limestone which

favour the growth of the tree, and the consequence is, that the cypress may be seen fringing limestone precipices, where you would suppose that no vegetation could possibly grow—in places, indeed, where the only vegetation perceptible consists of these cypress trees, growing, as it were, out of the very crevices of the rocks. But, as regards funeral aspect, the most mournful looking tree in the Himalayas is the fir, which is named the *Abies Smithiana*. That, indeed, has long, pendant foliage, of a very weeping, mournful appearance, but still impressive and picturesque, especially when combined with other foliage, and more particularly, perhaps, when it is adorned by the beautiful golden red of the Virginia creeper. Imagine the bright scarlet leaves of the creeper winding about amongst the dark coloured, mournful-looking foliage of the fir, and you have a delightful picture.

Then another tree, most beautiful in the Himalayas, is the yew. It does not grow there singly, as it does in this country, but in a few spots among the Himalayas it grows in a dense forest, limited in size, but extremely thick; and nothing can equal, from an artistic point of view, the beautiful forms of these dependent branches and the foliage of these yews. The beautiful lines of Wordsworth are applicable to these yew forests—

"Joined in one solemn and capacious grove  
Huge trunks, and each particular trunk a growth  
Of intertwined fibres serpentine;  
Nor uninformed with phantasy, and looks  
That threaten the profane—a pillared shade.  
Upon whose grassless floor of red brown hue  
By sheddings from the pining umbrage tinged  
Perennially . . . . . Ghostly shapes  
May meet at noon-tide."

Lastly, I should mention the juniper. This tree is extremely fine in the Himalayas; and when I mentioned to you just now that the trans-Indus range, near Afghanistan, was almost treeless, I ought to have made one exception in favour of the juniper. We hear now much of the Bolan Pass, and of Quetta, but the only valuable timber you have near Quetta consists of juniper forests, which grow near the summits of the limestone formations, 10,000 or 12,000 feet above the sea, which overlook those valleys, now so interesting to us from a political point of view.

Then, passing from this great natural order of *conifera*, we come to the other trees which are very familiar to us all in this country, the ilex, the oak, and the walnut, which are found in great abundance at Simla, where, as you know, is the residence of the Governor-General and his Council in the summer months. Near Simla, there grows the holly. In that locality it is not a shrub, as it is in this country, but a very fine tree of 50 to 60 feet high. I ought also to mention the plane tree. The plane tree is a great glory and ornament of the happy and world-wide celebrated valley of Cashmere. The scenes of the poem, *Lalla Rookh*, were laid in the midst of plane groves. Plane trees formed the ornament of the gardens of the great Mogul on the margin of the beautiful lake of Cashmere. The famous wooded island which stands in the midst of the lake is adorned with plane trees; in fact, in Cashmere, the plane is the crown and glory of the valley. In the eastern part of Himalayas, near Darjeeling, we have the maple; also the magnolia, which is brilliant with masses of white flower, so that it looks in the

midst of summer as if it were sprinkled with fresh snow. The laurel grows there to a great height, not like the shrub as we see it here, but a great tree 70 to 80 feet high. The tree fern probably the most graceful member of the vegetable kingdom to be seen in the world—the tree fern the eastern Himalayas. No word-painting of mine can give you any idea of the minutely graceful character of the foliage of the tree, especially, as it is generally seen with the distant background of the highest snow mountains in the world.

Before we leave the Himalayas, I must say a word about the rhododendrons. The discovery of the Himalayan rhododendrons is mainly due to Joseph Hooker, the distinguished director of the establishment at Kew. With great toil and hardship, and with much exertion, he discovered and brought to England specimens of most of the finest species of rhododendrons. The tree does not grow there in shrubs as you see in this country, but attains a height of 20 to 30 feet. Its flowers, as in its native habitat, are almost as large as man's head. The leaves found on the trees there are 12 to 13 inches long. The branches and the trunk are permeated with a sort of colouring matter, so that the whole of the tree seems ready to burst out with red; anything more magnificent than the appearance of this tree cannot be imagined. It is generally found in the midst of very rocky scenery; it flowers with great abundance, at altitudes of 12,000 to 13,000 feet and that generally at a season in May and June when the long winter of that region has hardly passed away, so that the rich flowers are fresh and bleached in a day or two after blooming in the masses of fog and driving rain, and sometimes even of sleet, to which they are exposed.

So much, then, for the trees of the Himalayas. I regret that time does not admit of my dilating more fully upon them.

I must pass rapidly on to the trees of the plains. The first I shall mention of course is the teak, or *Tectona grandis*, which is the queen of trees in the plains, just as the cedar is the queen of trees in the mountains. It is said that enthusiastic foresters to possess every virtue of which wood is capable. It is good under ground, it is good on the water, it is good in the burning sun, it is good everywhere, under all circumstances. It carves well; in light, it is durable; it will stand wet, and is seldom affected even by insects. It is used, as you know, largely by the British Admiralty. Its appearance always attracts the eye of the observer on account of the arrowy manner in which it shoots up. Even the young tree, which is hardly four or two above the ground, always looks like an infant giant, or a young Hercules, amongst trees by the striking manner in which it rises from the ground and seems to aspire upwards.

Then there is *säl*, or *Shorea robusta*, which is commonly called the iron-hearted *Säl*, on account of the great strength and durability of the wood, but it has not nearly so many virtues as the teak, especially in that it is so very heavy. But its appearance is very fine, with a tall, straight trunk and branching head. It is to be found in the greatest perfection near the source of the Nerbudda, near the point where the two ranges of the Sathpuras and Vindhya unite. Next I show

the two finest kinds of the natural order *minalia*; the *arjuna*, or anjun, is remarkable beauty of its trunk, which can only be a great marble pillar. The trunk is also-  
 is, bright, and smooth, generally growing  
 is, on the margin of streams, and in a very  
 te. The trees I have hitherto been  
 grow in the cool, but this tree  
 the midst of the greatest heat. The  
 of terminalia is the *Pentapteru tomentosa*,  
 hat is the very opposite in appearance.  
 having a white and smooth trunk, it  
 ck and rough trunk, and, as the two  
 grow in juxtaposition, the effect is as  
 a saw a pillar of smooth white marble  
 lar of black rough stone placed close  
 Then there is the *Pterocarpus marsupium*,  
 also a tree with a black-looking bark.  
 distinction to them, I may mention the  
*Boswellia thuriferu*, commonly called the  
 use-tree. I have just mentioned the  
 which has a rough, black bark, and, in  
 to that, I mention the salai. Instead  
 bark, it has white bark; instead of a  
 trunk, it has a winding, bending, strag-  
 ank, with branches thrown out in a kind  
 wayward manner. The salai, in sum-  
 , may be called the ghost which haunts  
 ts of India.

es which I have just mentioned grow always  
 contain ranges of British India, as contra-  
 shed from the Himalayas; but I must now  
 some of those which grow in the plains.  
 of all there is the babul, or *Acacia arabica*.  
 the one tree which is universal in India,  
 used almost for every purpose which is  
 in the daily lives of the natives. Then  
 the mango-tree, which is known, of course,  
 country on account of its fruit, and which  
 as a staple article of food to the mass of  
 ple. But it is also valuable for timber. It  
 in fine avenues on the sides of roads, and in  
 groves near to the Hindoo temples. Then  
 the sundar tree. You have often heard of  
 underbunds, that great, semi-marine forest  
 grows on the low, sandy region near the  
 of the Ganges. They are called the Sunder-  
 but that name is really derived from the  
 which is the principal tree in that part of  
 est, extending for thousands of square miles.  
 forest, the most remarkable tree is the  
 from which all the country boats of Bengal  
 k. As you may have heard, the river traffic  
 in Bengal is, perhaps, the most extensive  
 of the kind in the world. The network of  
 navigated by hundreds of thousands of  
 The boats there are to the inhabitants what  
 wagons are to the inhabitants of other  
 ; and all these countless boats are made  
 of the sundar tree, which grows in the forest I  
 ribed, near the mouth of the Ganges.

we have the different kinds of fig tree, or  
 here is, first of all, the ordinary *Ficus*,  
 known popularly throughout the world as  
 the tree. That is the tree under the shades  
 whole regiments are occasionally en-  
 It is the tree which you have read of  
 , and in the works of many modern  
 the beauty of the tree consists in the  
 which it throws down tendrils from

its branches, which take root in the earth and form  
 fresh trunks; so that a finely-developed banyan  
 tree looks like the interior of a great Gothic struc-  
 ture. The tree has its colonnade, its arches, its  
 aisles, its naves, and its transepts, and its roof  
 consists of the densest foliage, so that the per-  
 spective view, taken in the interior of one of these  
 great banyan trees, is, perhaps, the finest sylvan  
 subject which the artist can possibly have for his  
 brush or his pencil. Then there is the pipal, which  
 is called *Ficus religiosa*, which is to be found near  
 every Hindoo temple. It is remarkable for the  
 manner in which its branches entwine themselves  
 amidst the masonry. You know the old song—

"Creeping where no life is seen,  
 A rare old plant is the ivy green."

Similar to this is the *Ficus religiosa*. It is  
 always to be found in the midst of ruins; in fact,  
 it is one of the causes of old buildings becoming  
 ruins, for once it insinuates itself into the building,  
 it gradually works its branches and its tendrils  
 through all the interstices of the masonry, until  
 possibly the whole structure is embraced in its  
 fatal grasp. The building then becomes like a  
 human being seized by a boa constrictor, or like  
 the Laocoon encircled in the folds of the Python.  
 Lastly, there is the *Ficus elastica*, or india-rubber  
 tree, which many ardent foresters believe will, ere  
 long, more than rival the india-rubber trees of  
 South America.

Then there is the bamboo, the beautiful feathery  
 bamboo, which affords the means of constructing  
 almost all the huts, cottages, and villages of the  
 inhabitants of Bengal. But, besides what may be  
 called the domesticated bamboo, there is the wild  
 bamboo of the forests of Central India, which is  
 truly a lovely tree. A single shoot of the bamboo  
 has been shown at an exhibition, to the height of  
 80 or 90 feet, with a little flag at the top. These  
 bamboos, too, generally overhang the pools of  
 rivers, so that taking these great, beautiful, grace-  
 ful bamboos, bending over the stream, and the re-  
 flection in the stream—together forming almost an  
 arch in appearance—a more picturesque object  
 cannot possibly be imagined.

Lastly (I hope I have not wearied you by des-  
 cribing these various trees) we come to the palm.  
 Now, the first of the palms to be mentioned is the  
 date-palm, that is the kind which is known to  
 poetry as the feathery palm. Our Indian date-  
 palms are, no doubt, not so fine as those of the  
 valley of the Nile, and on the banks of  
 the Tigris and Euphrates, which run into  
 the Persian Gulf. Still, next after these, our  
 Indian palms are the finest in the world. Some-  
 times they grow singly, but often they are to be  
 found in great clusters, and often in long, straight  
 avenues. Then we have the Palmyra palm, with  
 great fan-like leaves, just like a human hand  
 stretched out. It is, perhaps, more noxious than  
 beneficial, for from it some of the strongest spirits  
 in India are distilled. Then, lastly, I shall finish  
 my mention of trees by describing the cocoa-nut.  
 Now, the cocoa-nut, probably, taking it all in all,  
 is the most useful tree of all the trees in India, for  
 it is commonly said—and truly said—that the  
 cocoa-nut will provide everything which a human  
 being can require. It will give him the most  
 nutritious food, slightly oleaginous, perhaps, but

still very strengthening; it will also give him the sweetest and most delicious drink; it will afford him everything that he can require for clothing; it will furnish him with roofing for his house; and it will give him not only the roofing, but the rafters. It will supply timber for the pillars upon which the edifice rests, and it will also give him the best material for rope; so that there is not a single use which man can require in the vegetable world which is not supplied by the cocoa-nut, and the cocoa-nut of India is second only to that of Ceylon, if, indeed, it is second. It grows in the greatest abundance all along the Malabar coast. There the cocoa-nut tree constitutes a little freehold—a little property—for actually the land revenue in some districts is based upon the cocoa-nut trees. That is to say, a man and his family get their living and pay their revenue out of a few cocoa-nut trees, so valuable is the tree.

Now, I wish I could dwell much longer on all these beautiful, interesting, and useful kinds of trees in India. I have hoped to induce you to feel an affectionate interest in them, to love the forests, so that they may live in your imaginations as they live in mine. But, from this brief summary of the subject, I must pass on to the question of how all this vast national wealth should be preserved.

Before doing so, I must first say something as to the reasons why the trees are valuable. They are valuable you will find, I think, for two main purposes, one economic, and the other climatic, and I will touch upon each of these subjects separately.

First, I will allude to the economic purposes. Now, the preservation of forests is desirable for the purpose of conserving the great wealth with which nature has endowed India for the use of men. There are no less than 37,000,000 of inhabited houses in British India, and I need not say that for every one of those houses wood is required. The majority of these 37,000,000 houses are constructed mainly of wood, so you can imagine from that what an enormous demand there must be in the vast British Indian population of 200,000,000 persons for timber for house building alone; besides, there are 40,000,000 of inhabitants of native States. Again, most of the domestic implements of the people are made of wood. No doubt, implements of various metals are being substituted for implements of wood, but, still, wood enters more largely into the consumption of the Indian population than that of most populations in the world for domestic implements. Among agricultural implements, take ploughs for instance, there is no accurate return of the number of ploughs in British India, but the best returns show at least 8,000,000 of ploughs. That, probably, is much below the mark. If you consider that there are not less than half a million villages, if there are 10 ploughs to a village, that would give 5,000,000; if there are 20 ploughs to a village, that would give 10,000,000; and if, which is much more likely, there are 30 ploughs to a village, that would give, perhaps, 15,000,000. From these facts you can judge what an enormous demand there is for wood, even for implements of agriculture. Then there are the carts. It is almost impossible to give any idea of the number of carts. There is no proper return of them, I am sorry to say, but they must be

counted also by many millions; and as for the boats, in some parts of the empire they are also to be numbered by hundreds of thousands. Then, also, there is the consumption of fuel. Now, to meet the demand for all the purposes I have been hitherto mentioning, wood is somehow found from the forests; but, for fuel, there is, in most parts of India, an absolute want of wood, and the consequence is that the people use for fuel the cow-dung which ought to be used for manure. You hear very much in India of the gradual exhaustion of the soil. I hope (and that is all we can say) that the exhaustion is very gradual. It certainly does appear, from many proofs, to be very slow. But, at all events, the gradual exhaustion of soil is to be feared, unless the people can have some better means than they have at present for obtaining manure. At present, much of the natural manure of the country is being used for burning, and you can imagine from that what a grave disadvantage is inflicted upon a country from the want of the conservancy of the forests. In fact, the agriculture of the country is suffering greatly from this cause. So much for economic purposes.

You will readily perceive how numerous and extensive the markets must be for timber and fuel, how difficult it is to keep them adequately supplied, and yet how fatal to the country it would be if they were to become depleted. Without a system of State conservancy, the forests would shrink and shrink, while the population increases; materials in wood and timber would become scarcer and scarcer; the price of fuel would rise, so as to press heavily upon the poorer classes.

But there are other purposes, namely, the climatic. There are many people who think the droughts with which India is periodically visited arise from the destruction of forests. Too much, perhaps, must not be made of that cause. There is a certain amount of evaporation from the Indian Ocean, there are certain masses of clouds, and they must condense somewhere, so I do not suppose the total rainfall of the continent of India can possibly be effected by forests; but the distribution of the rainfall is probably very much affected. The clouds pass over the dry plains, and go straight on to the mountains. They arise in the Indian Ocean; the first obstruction they meet with is from the wall of hills which I have described to you along the western coast, but, passing over this wall of hills, they sweep over the dry plains of India, and then they meet with the Sathpura and Vindhya ranges, which I have described. They are stopped there; they condense on these ranges, and then enormous torrents of rushing streams to arise and swell the rivers. Thus the clouds return back to the plains in the shape of floods, and sweep away the railways, viaducts, and carry roadways to destruction, and so effect numerous damages. Now, a great deal of these floods might have been avoided, had the clouds been arrested in their course over the plains, and this arresting can only be brought about, in the opinion of the best judges, by the preservation of the forests. If the forests exist, a cool surface is presented to the clouds, which causes them to stop and condense into rain, and drop fatness on the earth. If there are no forests, the clouds pass

in the upper stratum of the air, until they are stopped by the hills.

The same description applies to Bengal; the rains arise from the Bay of Bengal, and are stopped over the plains of Bengal, and are stopped by the great mountain ranges which divide Bengal from Burmah; or, again, they sweep over the great valley of the Ganges and Jumna, until they are checked by the Himalaya. Time does not permit of my properly entering into this meteorological subject, but you will see, from these main facts, how very probable it is that the existence or non-existence of forests may greatly affect the distribution of the rainfall. If there are no forests, the probability is that at one time there will be droughts, and at another time immoderate rains, a period of floods almost always follows, according to past experience, a period of drought. It is to the forests we must partly look for being blessed with the early and the latter rains in the season.

Now I pass then to another point with regard to climatic influences, viz., the retention of moisture. There is no doubt that forests produce this result very considerably. If the vegetation is destroyed, the streams run dry unseasonably, and the wells have but a scanty supply of water. If the vegetation is preserved, the excessive moisture of the dry season is stored by a natural process, for the soil man during the dry season. More especially is this important in those parts of India where canals have been constructed. Some of the canals of India are drawn from rivers which have their source in the Himalayas, in the perpetual snow, and for some forests are not of great importance. But many of the canals of India are drawn from rivers which rise in the mountain ranges of India itself, and if these mountain ranges are denuded of vegetation, those streams which feed these precious canals will all run dry in seasons of drought, so that, if we are to maintain our great canal system in full efficiency, we must preserve the forests near the sources of those rivers.

One more point with reference to climatic considerations, and that is the preservation of pastures. The cattle in India have too much food at some seasons, and too little food at other seasons, and the consequence is that the animals, which have been suffering from depletion or inanition during the dry months, are apt to surfeit themselves as soon as the vegetation bursts forth into leaf upon the commencement of the annual rains. Now, the great object is, by preserving forests, to preserve the grass during the dry seasons. If there is a certain amount of vegetation, the grass is sheltered from the burning sun, and it thrives and affords fodder for cattle, whereas, if all the vegetation is swept away, grass will not survive. For that reason, many experienced men think more ought to be done in the plains of India for the establishment of what are called communal forests, and that every village, or cluster, or circle of villages, should be induced or compelled to combine for the establishment of communal forests, which shall afford a certain amount of timber and fuel, and shall also preserve the grass for the cattle. These are the main reasons, in brief, why the preservation of forests is a matter of such vital importance and national concern in India. It then comes to the measures to be taken for pre-

serving these forests. I have sorrowfully admitted to you the neglect on this subject, which has prevailed in former years. Nobody is more zealous than I am in vindicating the character and conduct of our Government and officers in India, but I must admit that in respect of the preservation of forests, we have not, until within the last 20 years, done as much as it behoved us to do. I attribute that not to any wilful neglect, but simply to the fact which I stated at the outset of my address, namely, a want of knowledge. It is the deficiency of technical education on this subject which has caused the partial destruction of these great sources of national wealth—a wealth too, which, as you see, is essential to the well-being of the country. But, of late, we have been mending our ways in that respect, and we have established a very highly organised department of forestry. We now have a large staff of trained forest officers—I wish I could add that they had been trained in this country. You may have seen lately that there is a project for establishing a forest school in England, in connection with the forest of Epping; hitherto, however, our English forest officers have been trained, not in their native country, but in France and Germany; and we must acknowledge the great debt we owe to our gallant neighbours, the French, for the excellent forest school of Nancy, which has given us many English officers for the benefit of the Indian forests. Still, I do not see why forestry should not be taught in England as well as anywhere else. You do not require a very large or extensive wild forest, in order to learn the principles of forestry. Any of the numerous woods and covers which adorn the undulating valleys of England would do perfectly well for instructing Englishmen in the art of forestry, to say nothing of the woods which may be found in Scotland or Wales. But, at all events, it matters not so much where the men are instructed, as that they should be well instructed somewhere; and I am happy to state that we have now a Forest Department of India which, in respect of scientific, technical, and practical knowledge, is second to no similar department in the world.

Now, you will ask, what exactly does this great department do? In the first place, the remaining forests—I must call them remaining forests, because you see how the ancient forests of the country have been destroyed—are divided into two great categories. They are divided by law (for the matter has received careful attention from the Legislature) into two classes; firstly, reserves, or the forests which are absolutely guarded; and, secondly, the protected forests, which are imperfectly guarded and preserved. To give you any idea of the extent of these forests, I must mention to you the area in square miles, and you will find that at first sight the area does present a respectable aggregate or total. In the Punjab there are now 4,000 square miles; in the North-West Provinces, 3,000; in Bengal, 9,000; in Assam, 7,000; in the Central Provinces, comprising the Sathpura and Vindhya ranges, which I have mentioned several times, 20,000; in Berar, 5,000; in several miscellaneous districts, 1,000; in British Burmah, 2,000; which are, probably, the best forests in the empire. All these make up, for the Bengal Presidency, a total of 51,000 square miles. To this you must

add 13,000 square miles for Bombay, and 5,000 for Madras, which make up a grand total of 69,000 square miles, or, say in round numbers, 70,000. This sum total will, ere long, be augmented, because there are many thousand square miles yet to be marked off in British Burmah, and, I believe, there are some thousands of square miles also to be marked off in Southern India, within the limits of the Madras Presidency, so that, I dare say, within a few years, we shall have not less than 100,000 square miles of forest in India, which, I hope, is a figure worthy of being mentioned before a distinguished Society like this. But it were vain, if I were to lead you to believe that the whole of this area, of 70,000 square miles, is properly protected; I am afraid that the greater portion of it is imperfectly protected; but, still, I think that nearly half is really well preserved; and I see that the Famine Commission, in the very careful report they have recently made on the resources of India, say that 25,000 square miles are thoroughly guarded and preserved; but at all events, the whole of this great area is, more or less, under some protection and supervision.

The Forest Department, as above described, manages directly all the forests technically described by law as "reserved," and supervises the management by the ordinary civil officers of the forests technically described as "protected." From these forests, the markets for timber and fuel are largely supplied. The proceeds for all British India amount to about three-quarters of a million sterling annually, and the expenses to half a million. Thus, the department defrays all the charges for the conservancy, and yields a small revenue to the State. Many articles of wild forest produce, such as gall-nut and sandal-wood, are sent to the great marts for exportation abroad.

Besides the area of forests, as above set forth, there are extensive areas of jungle of equal, probably more than equal extent, left in the hands of the people, under the terms of the Land Revenue Settlement. From these jungles most of the local wants of the country, as above mentioned, are supplied.

The first-class timber markets are, however, supplied from the "reserved" forests, and the second-class timber markets from the "protected." From both kinds of forests excellent fuel is obtained.

The railways were at first worked with wood fuel; but coal is largely used, now that the mines are being opened. With a good conservancy system, however, there ought not to be any apprehension on account of wood being consumed by the railways. For forests could, in many places, be formed all along the lines of railway, and would supply fuel, while improving the country.

Then the question arises as to what does this preservation and guarding consist of, and to what intents and purposes are the forests protected? Well, now, they are first protected as to the matter of wood-cutting. The forests are not treated by the Government as if it were the dog in the manger. Timber is intended for the use of man, and the object is not to preserve the trees for ornament, but for use. As soon as a tree has attained its utmost development, and grown to its full height, it is fit to be cut, and ought to be cut; and in many cases trees grow so thickly together

that thinning of them is a positive benefit to the vegetation of the forest. So, then, the restrictions upon wood-cutting are not made absolute, but are instituted in order to insure that a certain number of trees shall always be left for reproduction.

The next point is to regulate the practice of what is called "rab." Now, rab means this—that the new shoots and sprigs of the trees are burnt, and their ashes are used for manure. You will readily understand that such ashes contain many of those chemical constituents which are needed for manure, especially where much of the natural manure of the country, viz., the cow-dung, has been used for fuel. Now, this practice of cutting the sprigs of trees, and burning them for ashes for manure, is a practice which, if not regulated, will cause great damage to the forests; but, nevertheless, to a certain extent it is necessary.

Then another matter is the prevention of the jungle fires. These jungle fires are partly accidental and partly intentional. When they are accidental they present some of the most magnificent spectacles you can possibly imagine. I, myself, and many other people in India, have been sometimes out at night in the midst of these fires, and you then see some of the grandest, if not, perhaps, the most alarming sights you ever witnessed. The way in which the devouring element rushes over the country, travelling sometimes at the rate of several miles an hour—the wild animals fleeing before it in terror, the native inhabitants of the forests sometimes even being caught in the flames and being burned to death, poor men, and occasionally even mounted Europeans having to gallop away to escape from the vast rushing conflagration—all these things constitute a wonderful sight. Then, the manner in which the trunks of the trees form as it were pillars of fire, or the clumps of bamboos rattling and crackling just like the roll of musketry, and sometimes the sound of the falling forest, and the roar of the flames is not unlike the resonances of artillery or the thunder of Heaven. Again, the manner in which some of the trees smoulder is quite wonderful. Stories are told of trees sometimes burning for many months together, and one I heard of, or rather read of, as having burned for three years consecutively. First, the trunk smouldered, then the fire got to the roots, and gradually burned through the radicles for months and months together.

Now, you will readily imagine what mischief is caused by such conflagrations as these spreading over many square miles. Yet the cause of the accident is often trifling, a wayfarer lighting his pipe, a labourer cooking his dinner (after the Oriental fashion) in the open air. With a system of conservancy, these accidents are minimized, or almost prevented altogether. Without such a system, they become terribly frequent.

But the fires are also intentional, and are lighted up every year to insure the plentiful growth of fresh green grass for the grazing of the cattle. Of course, to some extent, that is permissible, and the hills at the back of Bombay, in the months of April and May, are lighted up at night with a magnificent illumination. In fact, so popular is the practice, that, whenever there is any political disturbance anticipated, the natives say "the fire will be out on the hills," and

from that we understand there is going to be a disturbance.

There is another way in which the burning of the fires are intentional, viz., this, there are many wild hill tribes who carry on their agriculture, not by means of ploughing, but by means of burning fires, and letting the ashes lie on the ground until the rains come. Then the rains descend on the virgin soil, which, fertilised by the ashes of the burnt forest, produces abundant crops without any further labour whatever. This, of course, is an utterly barbarous practice, and it arises only from the ignorance of the people. No doubt the localities are often very steep, and it is not so easy to plough as it would be in the plains, with these very sharp gradients. Nevertheless, the practice arises from ignorance on the part of the people and from their want of agricultural capital. The object of the British Government is to wean these poor people from the barbarous practice, to reclaim them from habits of agricultural savagery, and to make small advances of money to them for purchasing ploughs and plough cattle, and so teach them to depend on settled agriculture rather than on these wasteful destructive fires.

Then, another purpose to which the forest conservancy is directed is the preservation of the grazing. If the cattle are allowed to wander unchecked in the jungle, they will eat a little and destroy very much; that is to say, they will tread down and trample and destroy uselessly ten times as much as they consume for food. The object, therefore, is to restrict the grazing by means of a sort of block system, that is to say, to allow the cattle to graze in certain blocks or areas of forest range, and to prevent them grazing in others. The block or area is protected from grazing, and as soon as its vegetation has grown up, then the cattle may be admitted to graze safely. Of course cattle must have pasturage, and the object should be to provide pasturage ground sufficient for their real consumption, but to prevent them from needlessly destroying the vegetation.

It is this useless destruction of the pasturage, from want of conservancy, that renders the country so destitute of fodder whenever drought occurs. It is essential to husband the spontaneous fodder of the country, as a resource to be available in time of need.

In all these matters you may readily perceive that the question arises of the restriction of the rights of the people, and there is, to some extent, a slight contest always going on between the forest officers and the ordinary civil officers of the Government. The forest officers, of course, are zealous for preserving the forests, and the civil officers naturally protect the rights of the people. The object is to maintain a judicious compromise. The people who sparsely inhabit the forests have been accustomed to cut, burn, and destroy somewhat recklessly, and they cannot speedily be reclaimed from these evil habits. This can only be done by degrees. But while, on the one hand, their reasonable rights are protected, on the other hand, they must not be allowed to destroy forests altogether, otherwise there will be no *corpus*, as the lawyers say, on which any rights are to be founded; the whole property of the country will be destroyed, the natural wealth will vanish, and there will be nothing for any-

body to have rights in at all. So that, in a judicious gradual and conciliatory manner, forests must be preserved, while a fair and equitable consideration is given to the well-established customs of the country, notwithstanding that these customs are, to some extent, objectionable.

The "reserved" and "protected" forests, technically described above, have been adjudicated, after inquiry, to be the property of the Government. Full provision is made by law for determining disputes between the people and the Government authorities regarding the ownership of the forests, and the boundaries are defined of the jungles which belong to the State and to the natives respectively. An ample quantity of jungle has everywhere been marked off as belonging to the people, and within that area no restrictions are placed upon the natives. The restrictions exist only in those forests which from time immemorial have belonged to Government under native dynasties as well as under British rule. Within some of the Government forests, especially in the technically "protected" forests, subordinate rights are found to pertain to the natives, under the Government, as lord of the manor. Those rights are also investigated under the law, and defined.

Thus no just cause of complaint whatever is allowed to exist on the part of the people against the forest system, though there is no disguising the fact that many would desire to cut down the State forests at their will for immediate gain, without any care for the future.

There are certain things which in all countries are recognised as pertaining to the business of the State, or rather public authority, such as the coinage, the post-office, the electric telegraph, besides the important departments of sanitation, education, and the like. In some great branches, the State, if it does not directly undertake the management, does yet interfere considerably, notably in the case of railways. Now, in India at least, forest conservancy is to be classed in this category. There are many things in which private enterprise is better than State action, but forest conservancy is not one of these. The saddest experience has shown that if forests are left to private action unrestricted, they will be destroyed. Hundreds of tracts are to be seen in India, now bare and barren, where forests and vegetation once abounded, and might again abound under a proper system of conservancy. Hundreds more of tracts exist where the denudation has occurred within the present generation. Sadder still, in many places the mischief is irreparable, because the soil has been, after the loss of its vegetation, washed away by the action of rain. If left to themselves, the people would work out the forests to destruction, just as a spendthrift lives on his capital—in homely phrase, they would kill the goose which lays the precious eggs. The true object of conservancy is to preserve the forests as an inestimably valuable capital with which nature has endowed us, and to draw from these, for the use of the people, interest, in the shape of timber fuel and other produce judiciously cut or felled, and grass or fodder grazed according to a scientific system. It is this which is now being done effectually, though but too tardily, in India. If forests are worked without any State supervision, they are exhausted, and

nothing is left for reproduction. If they are worked by the State, then some trees are always left to keep up the vegetation.

I have now touched briefly, and I am afraid imperfectly, according to the short time at our disposal, on the nature of the forests, on their value, climatic and economic, upon the means which should be provided by the Legislature and the executive for preserving them, and the objects to which that preservation is directed. Before I resume my seat, and invite discussion on these very interesting and important topics, I would desire to re-call to the grateful recollection of patriotic Englishmen, the names of some of our countrymen who have most distinguished themselves in respect of forest conservancy in India, but I must first mention two distinguished Germans. It has always been the pride of the Indian Government to attract to its service eminent men of other nations, and amongst its best servants is Dr. Dietrich Brandis, who has done more for forest conservancy than any other person who could be named, for not only has he organised a system which is scientific and practical, but he has also contributed much to botanical science in India, and is the author of an excellent work, entitled "The Forest Flora." Next after him I would mention his distinguished countryman, Dr. Schlich, who, for a long time, was Conservator of the forests of Bengal and Assam. After them I would mention Dr. Cleghorn, of Madras, who I am happy to see present amongst us this evening. Then there is Dr. Stewart, the late Dr. Dalzell, of Bombay, Mr. Reddome, and Maj. Campbell Walker, in Madras; Col. Pearson and Capt. Forsyth, of the Central Provinces. Capt. Forsyth was one of the men who worked so hard in the forests, that I may say he almost laid down his life for their sake, and has left, as the memorial of his labours, one of the most charming books on forestry that has ever been written. In Burmah, the forest department has been well represented by Messrs. Seaton and Ribbentrop. Then I may mention the two other zealous officers who are now carrying on forest conservancy under great difficulty in the Bombay Presidency. These are Mr. Shuttleworth and Col. Peyton, and lastly I would particularly mention a member of the Covenanted Civil Service, Mr. Baden Powell, in the Punjaub. These are the men who have struggled to preserve our forests through evil report and good report, with a considerable measure of success, and who have, from their sense of public duty, from their regard to the welfare of India, and from their love of the forests, borne much hardship, have endured many toils, and have risked their health, and some even have lost their lives in the service of the forests of India.

It is a cause of thankfulness that scientific and practical forestry is taking a hold upon the public mind in India. The European civil officers of the Government are beginning to understand the subject, and to co-operate with the regular forest officers. Schools of forestry for the natives are being established.

In conclusion, this subject, which I have, I am afraid, imperfectly treated in the brief space of an hour, is worthy the best attention of such a body as the Society of Arts. This Society has influenced Englishmen in many directions, and I venture to say that there are few directions in

which the influence of so learned, influential, and practical a Society as this can be more beneficially exercised than in furthering the interests of forest conservancy in India, which is the greatest of the dependencies of England.

#### DISCUSSION.

Dr. Cleghorn said it had given him great pleasure to hear Sir R. Temple's description of the forests of India, and of the improved management which now existed. In December, 1856, he was called upon to begin at the very beginning, as the first forest officer appointed in Madras; his friend, Dr. Brandis, began his duties in Burmah about the same period. In Bombay the work began a little earlier, but in the north it was not until 1861, and in 1862 the first Forest Act was drafted. Since then the organisation had extended over the whole Empire. He rejoiced very much to hear that the results had been such as they had heard. There could be no doubt that the evils of denudation at the head waters of the large rivers were very great. He had travelled up the Indus, the Irrawaddy, and the Godavery, and of the evils brought out in the concluding chapter of the Famine Commission Report no one who had witnessed them could have the smallest doubt whatever. He had also visited the head waters of the Cauvery and other large rivers which rose in the Western Ghats, and there could be no doubt of the terrible evils which arose from denudation. He had visited forests in 1855 and 1856, where there were wild deer in considerable abundance, but where there was now not sufficient vegetation to afford them shelter, and they had all disappeared. One of the many causes which led to denudation was the ramification of railways, for in the course of two or three years the demand for fuel alone generally led to an almost total denudation for ten or twelve miles on each side of the railway.

Sir Joseph Fayrer, M.D., K.C.S.I., F.R.S., being called upon, said he had not come at all prepared to take any part in the discussion, but he had been much instructed and interested in what he had heard, and congratulated the Society very much on the communication which had been made by one so well qualified to make it. No governing authority in India had ever done more to foster and encourage the development of science than the gentleman they had had the pleasure of listening to, and he was glad to have this opportunity of paying his tribute of admiration and gratitude for the encouragement which Sir Richard Temple had always given to science in India; he was perfectly certain that sooner or later, all scientific men would endorse that opinion. The subject of the address was not one upon which he was qualified to speak, as he had never been a forest officer, but he had always taken much interest in the question. He had seen a great deal of the forests in India, and had travelled amongst them. If there were one point which he should emphasise more than another, it was one which had scarcely been touched upon, namely, the great importance of these forests upon the health of the enormous population of that great country. That population consisted of 250,000,000, and the country was as large as the whole of Europe, excluding Russia. Although the amount of the rainfall itself might not be much interfered with by the denudation of forests, it was much interfered with as to its distribution. There were large tracts of country in India, especially in the north-west, which were almost destitute of vegetation, and it was of the greatest importance that vegetation should be encouraged in those districts if possible. That was one of the directions in which forest conservancy might be most beneficial. With reference to the question of the denudation of the hill sides, there could be no doubt of its evil results, of which

were abundant examples in Europe; as, for instance, in Greece, and, perhaps, in Cyprus. You had only study the sides of that great range of mountains, the Himalayas, which extend for about 1,600 miles from east to west, with an average breadth of perhaps 150, and rising to a height of nearly 30,000 feet, and pouring down from the great water-shed the enormous rivers which run east and south-west, and which would, but for the forests which clothed those hill sides, inevitably try every year desolation and ruin by the floods they brought down. It had been said that endeavours ought to be made to cultivate the Terai, and take away the vegetation which retained the water, but nothing would be more destructive. It might be, and no doubt was, in a certain part of the year, pestilential from malaria, but if the vegetation were taken away, there would be but disproportion in the distribution of water which would be destructive. That was another direction in which forest conservancy might be well developed. Those who know the north-west provinces of India, who had been at Delhi and Agra at the commencement of the hot season, and who had travelled from there towards the west, knew that when they got within the shadow of the great range of hills, that an extraordinary change of climate was experienced; it was not a question of altitude, but of the moisture which was present in the atmosphere due to vegetation. Sir Richard Temple had referred to one very important point, the destruction of the grass; and he had seen a good deal of that. He had seen large trunks of jungle in flames, and the fire extending into the forests. He had seen large trunks destroyed, and, what was far worse, thousands of young trees blighted for ever. The object of these fires was to manure the ground, but it was a most wasteful process; and it was a very wise restriction which the Forest Department had put on their officers, that they should not allow those fires to take place where they could be prevented.

Sir William Robinson, K.C.S.I., desired also to express his thanks to Sir Richard Temple. He thought there was a good deal of imagination in the idea of the arid plains of the tropical India ever having been covered with forest verdure. It had no existence in fact within the memory of man, and could not be re-created. He himself was not so complete a believer in the climatic influences of these forests. He believed that great moisture-laden trade winds of the tropics were arrested by mountain ranges rather than by trees, and Sir Richard Temple had shown that that was pretty much the case. There was, no doubt, a moisture and dewyness about forest land in the low country, but this is all that can be affirmed. He had lived all his life on the west coast, and knew what the south-west monsoon was. It was not influenced by forests. He doubted very much whether famine droughts were created or influenced by woodland denudation. No doubt denudation had occurred, valuable timbers have been cut out and used, but cultivation had very much progressed; and within the 37 years he had been in India, it had much more than doubled. On the west coast it had very largely increased, and of course the forests had disappeared; and he did not think the substitution was a bad one. Exaggeration had characterised the whole argument. He would, however, admit that care must now be devoted to the preservation of forests where they existed; but he did not think the denudation had been anything like so large or wasteful as it was alleged to have been; for there was not a forest district round the circle of mountain ranges in South India, down to the Neilgherries and up to the Bombay frontier that he had not been in. There was a question which had been very little touched upon by the lecturer, and that was the proprietary right over the forest ranges of India. Forests were valuable, they had been valuable for thousands of years, and had been appropriated. Of course no one in that room supposed that the forest ranges of the west coast of India, which had enjoyed

a timber traffic of an enormous character with Arabia, Egypt, and the Gulf, time out of mind, was a "No man's land," which could be appropriated by the Government when it pleased. That was not so much the case in other parts, but still most of the valuable forests had been appropriated, and for hundreds of years had belonged to private individuals or communities; and when this forest conservancy began, it was a very difficult question how you could drive alien forest laws (alien to Englishmen as well as to Indians) amongst the ancient people of India. There were no public forest laws in England. You had to go to Germany, Austria, and the Tyrol to see what forest laws were. They were necessarily meddling, and we ought to be very careful how we dealt with our native subjects in this matter. He, himself, had been deeply apprehensive and anxious on the subject, for he knew it was a difficult question, even on the continent of Europe. Usurpations began almost as soon as British administrations came into the country on the west coast; and when what was called the East India Company's monopoly of timber and wood trade was introduced into Malabar and Canara, it was sternly opposed by Sir Thomas Munroe. It was proposed by the Bombay Government to have a conservator of forests there; the experiment was persisted in for 20 years, and the history of that period was very suggestive, and one which made men accustomed to these things very thoughtful and anxious. Happily, after the monopoly had wrought a great deal of harm, Sir Thomas Munroe happened to become governor; he took the question up, and the whole of this evil was swept away in 1822. There was a great temptation to usurp and carry forestry into places where the prescriptive titles were not very clear, and likely to be menaced. He had doubt himself about the wisdom of large State monopolies of forest and timber trade. In the meantime, with the exception of some such things which would require very careful watching, the Forest Department was doing fairly well. He thought, too, that the recent law on the subject was aggressive; it provided a separate establishment for the management of these questions of property and rights; there was a Forest Settlement officer, who had to go about challenging titles, and in Madras he might be as young in the service as four years. Then the appeal was to the Forest Court, created *ad hoc*, not to the ordinary tribunals of the country, which he did not think was wise or necessary, because, from the native point of view, the executive would be less independent; he accepted this view. Again the law was excessively drastic with regard to penalties, and as far as he understood, would enable transit duties to be levied on the timber trade of the country. One thing he was very anxious about was as to the assumption by Government of proprietary right in the village forests. A large portion of India, practically, belonged to the villages, but the new law, as it seemed to him, simply did away with all village property in forests and local woodlands, and was eminently resumptive.

The Chairman remarked that the question which Sir William Robinson was opening was so large that it would require a whole evening to discuss it.

Sir W. Robinson said the Forest Law laid down that there were only State forests and private forests, and practically denied to village and communal forests any existence. The State forests might be put under strict rules, but the old village communal areas ought not to be touched by the State under any circumstances whatever. The rights of the people should be strengthened, not challenged and interfered with by the law or State executive. Forest rules are plaguing the people.

Mr. Wm. Botly said his experience of agriculture in England, and also on the Continent, showed the necessity of maintaining and extending forests. They were not only picturesque but profitable, and would

will pay for planting in belts, even in this country. On the sides of mountains and hills they afforded shelter, both to cattle and also to growing crops, and, if this were true in England, by analogy it must be so in India. Forests also fertilised the land; he knew of land which 200 years ago would produce nothing but heather, but after having been planted with trees, was so much fertilised by the falling leaves, that it now grew excellent corn. He considered that any one who planted trees was a benefactor to posterity. With regard to agriculture in India, he wished the Government model farms were more generally extended, and that agriculture was more generally taught scientifically.

The Chairman said he would not himself trespass upon the meeting more than to say that, while Sir Joseph Fayrer was speaking of the pestilential character of the Terai, it leapt to his mind that, when he first went to Italy, forty years ago, the Marmura of Tuscany was quite as pestilential as the Terai of India ever was, but now, thanks to cutting avenues through the woods, and drainage, that pestilential character had almost entirely disappeared. He believed the time would come when even the Terai would no longer be looked upon with terror. He concluded by proposing a vote of thanks to Sir Richard Temple, which was carried unanimously.

Sir R. Temple, in acknowledging the vote of thanks, said he had only one word to add in conclusion. The area which he had presented, of 70,000 square miles of forest, more or less preserved, was held to be the property of the Government, the domain of the State. There might be within the domain certain subordinate rights, which he alluded to in the close of his address as the rights of the people. But outside this area, there would be the vast area of forest, of which he could not give the statistics (which must greatly exceed the 70,000 square miles), which had been allotted to the people, and in which their full right was entirely acknowledged, he hoped even to the satisfaction of Sir William Robinson himself. So that it was not to be supposed that, in preserving the forests, the Government was in any way invading the rights of the people. On the contrary, those rights would be most carefully acknowledged in the vast area of forests left in their hands, an area considered quite sufficient for their ordinary requirements. It was only regarding what might be called the first-rate forests, which had great economic and climatic value, that these important conservancy measures had been undertaken. 70,000 square miles was but a very small proportion of the total area of British India, which amounted to no less than one and a-half millions square miles, so that they had not got much more than 1-25th—hardly more than 1-30th—of the area under forest conservancy; and it would be admitted that, considering the circumstances of the Empire and its reasonable requirements, both economic and climatic, the area under forest conservancy, instead of being too much, was really too little. He hoped that one result of this subject being taken up by the Society of Arts, would be the further development of forest conservancy in India, and the consequence of that policy would be certainly to benefit the natives, for, after all, it was for their welfare that the British Government in India existed.

#### ADJOURNED ORDINARY MEETING.

Monday, January 24, 1881; HYDE CLARK, Esq., in the chair.

The discussion on Mr. Alfred G. Lock's paper on "Causes of Success and Failure in Modern Gold Mining," adjourned from 19th inst., was resumed.

The Chairman, in opening the discussion, said that he regretted having been unable to attend the last meeting, but he had read Mr. Lock's paper, which was a valuable contribution to one branch of metallurgy. He welcomed Mr. Lock as a fellow-labourer, having himself read a paper before the Society of Arts, on "Copper Smelting," in 1858. The paper which they had not to discuss was one of a thoroughly practical character, and fittingly brought before the Society an account of what has become a recognised department of English metallurgy, of particular importance at the present time. Although the English school had long since applied itself successfully to the working of copper, tin, iron, coal, and other minerals, gold working was a foreign pursuit, carried on by the Spaniards, Portuguese, and Germans. On the establishment of independence in South America, the English began to take a share in the gold and silver mines. In 1824 and 1825, numerous companies were formed with extravagant expectations, and many of which, although working old and rich mines, ended in disaster. A national advantage, nevertheless, accrued from these undertakings. The most intelligent captains and miners were taken from Cornwall and Wales, and they came back prepared to introduce at home still greater efficiency in their business. Abroad they made themselves masters of the native modes of working, and introduced many improvements and far better machinery. The companies, of necessity, were driven to try all kinds of new inventions and processes, and although some of them were of foreign origin, they all contributed to the formation of a satisfactory system. Some of the English companies, as the St. John del Rey in the Braza, have continued to yield large dividends to this day, while in other cases, though the companies failed, Englishmen remained in Mexico, Chili, and Brazil, working on their own account, or in association with natives, and bringing back large fortunes. Thus originated an English school of gold metallurgy, the work of which was chiefly carried on abroad, and therefore less known. The participation of the English in foreign silver industries was no less successful, and a large business at Swansea has been established as a market for various silver ores, while at Newcastle the process of Pattinsonising, invented by Mr. Pattinson, has enabled workers to treat not only British silver ores, but many Spanish ores. The Americans engaged about the same time as the English in gold enterprises, and the discovery of gold in Virginia and the eastern and northern States stimulated them. When the discovery of gold in California, and of silver in that State and Nevada took place, Englishmen were quite able to deal with the business, independent of any foreign help. The discovery of gold in Australia made gold mining an industry and profession within the empire, and the works in the several colonies of that region, and of New Zealand, do honour to the knowledge and intelligence of the population. It is these processes which Mr. Lock chiefly describes with the necessary detail. Few are aware what returns mining in the colonies and foreign countries bring to those at home, apart from any investment of capital. There are the remunerations for the sustenance of families, there are the remunerations of earnings and savings, and great quantities of machinery and supplies are obtained from our establishments. Mr. Lock's paper comes, too, at a convenient juncture, when the gold mining of India is justly attracting attention, and when the spirit of speculation is promoting operations in Venezuela and Guyana. In reference to engineering and chemistry, gold reduction has the greatest interest, because large masses of mineral have to be pulverised by natural or other mechanical means at the smallest cost to get at a most delicate property of the precious metal.

Mr. Smedley repeated the observations he had made on the former occasion with regard to the importance of

proved system in the management of mines. At that moment he was engaged in encouraging a system which he hoped to put into practice in a short time for the purpose of endeavouring to introduce, on a large scale, what was known as the tribute system, under which it was meant that every one who worked on the mines should be paid by results.

Mr Selwyn said, that although an admiral in the navy he had been connected with practical mining for many years, both in Western America and this country.

He had remarked that one of the great causes of complaints made, that there was so large a proportion of non-dividend paying mines, was the fact that the owners looked for rich ore, and took no care of the quality; it was only by impressing on them the necessity of getting the last cent out of every ton of ore that that could be got rid of. The processes pursued in America were amongst the most perfect known. There had been given something to California, but in Australia, in its clever machinery, which had been in Australia, had been the main-spring of the work. There were particular processes in Australia there which were, as yet, unknown in America. These were largely chemical processes, and when chemical processes were discovered, the man who discovered them was anxious to keep them as long as possible. He was tempted, by the facility by which he could take out a valid patent, to do it known in that way, but he did not propagate it and did who is interested in the results of the process.

If he were only a patentee, and not a miner, he might look at the royalty rather than at the results in the mine he conducted. Some men had invented tobacco juice to be put in the pans, sugar, salt, clay, and every kind of material which could possibly be useless. These things were not kept to themselves, but where they had used means of really deriving a larger proportion of gold from the ore than their neighbours, they kept to themselves as long as they could. He had seen both milling and smelting in America, and they thought they did very well if they got between 60 and 80 per cent. of the metal in the ore; in England they rarely rose to that. He did not say according to ordinary assays, because they were very unsatisfactory.

He had practiced assaying to some extent, and had made a very little mistake in the man who urged the process while the cupelling was going on would give false results. It was quite possible for a portion of the silver and gold present, as it was, to go up the chimney. In 1873 and 1874,

Utah, he took out ore which showed 60 dollars by the dry assay, whilst, by the humid process, 69 dollars per ton out of it, showing that a large amount was escaping by the other method. Another, who was the head of the Geological Survey in Canada, told him again and again that in Canada there were thousands of tons of crushed mining sulphurets of gold containing 3 to 5 ozs. of gold, and yet no one knew how to get it out. In the present state of chemical knowledge, that was ridiculous; but the instant you went there and tried to do it, you were met by exorbitant demands for a part of so-called owners of these refuse heaps, a practical metallurgist had very little chance. Only by the general spread of knowledge, by means such as Mr. Lock's paper, and the discussion on the subject, any great progress could be made. The process, of which he had just spoken, was effective in getting gold and silver, since no more came from the Western States which did not contain gold. He had evidence of that in working the New Consols Mine, near Callington, in Cornwall, where the ore was very poor, and if it were treated by a simple process, there would be even the poorest gold mines. This ore contained 3 to 5 tons of silver, 1½ per cent. of copper,

and a trace of gold, as the result of a fire assay. The results of 30 tons worked was 196 ozs. of silver, 1½ oz. of gold, 1 ton of copper, precipitate, 70 per cent., worth about £65, so that the total results were about £118 on the 30 tons of very poor stuff indeed. That process was one of roasting in furnaces with salt and, afterwards, of boiling in tanks with salt and muriatic acid. When he was in Utah in 1871, he had never seen or heard of either Anderson's, Longmead's, Augustin's, or Rhodin's processes, but it occurred to him that Nature must have had some solvent to put the metal into its present position, and he found that salt water, with a very small quantity of hydrochloric acid, used to boil the ore, would produce the whole of the contents in metal; further, that where gold, silver, lead, copper, or anything but platinum and tin, were present, it produced it in perfectly clear solution; where arsenic and sulphur were present, a chloridising roasting must precede the operation. But at this mine in Devonshire, their great error was that they had antiquated roasting furnaces, and that the quantity treated per day could not possibly pay with such a grade of ore. If you had a very low grade ore, it was necessary to treat a large quantity per day, and if any one part of the process failed to give the necessary quantity, the whole broke down. This was one of the first requirements, but it was utterly unknown in this country. Very little known also was the furnace on the plan of Stettefeldt, or O'Hara, which Stettefeldt would probably say was an imitation of his. That was a process in which chloridising roasting took place, by dropping powdered ore from the top of a chimney shaft into the flame of a furnace, occasionally fed with salt, or the salt was mixed with the ore. O'Hara did very much the same thing, but with a little less labour. This mine in Devonshire was furnished with self-acting tables, the inside worked by water-power; the rabble being fixed, it turned the ore over on the bed-plate. Stamping was not done at all, but the ore was crushed by a set of rollers, crushing it as fine as they could. In America, they wanted very much machinery which would do something more than the present stamp; and Blake's crusher served the stamps capitally, and always kept ahead, although the stamps crushed two and a-half tons per day per stamp head. In some instances, some improvement had been made by attaching rollers to the Blake's crusher; and he had heard that Mr. Marsden had a new crusher, which would fulfil these conditions. If that could be done, it was the most admirable machine which could be proposed for the mine, because stamps were very expensive, and did not do sufficient for the purpose. If you had a furnace which could roast 100 tons a day, and corresponding tanks into which to work it, either lixiviating or boiling, you ought to have a number of stamp heads sufficient to do that duty, and these stamp heads would cost more than all the rest of the plant put together. Besides that, they were extremely objectionable up at the mines, as they involved steam machinery to drive them, and you had to take enormous boilers for the purpose. He had seen teams of mules, 100 yards long, dragging a boiler up a hill; and the boilers rapidly wore out. He wanted to see a process initiated on a proper basis, with an understanding first of the chemical laws concerned, that the whole thing, no matter whether it was called the Washoe process or any other, consisted in the chloridising of the mills; that nature, when she put the metals into the rocks, had them first boiling in a hot, salt ocean, with an excess of chlorine. If you reversed that process, you had got the same thing to the last dwt. That could not be done but by examining first the question of the furnace. Stettefeldt's was a good furnace, but not the best that could be devised, because you had still to use some fuel and attention, both of which cost money; and as there was sulphur in most of the ores, which required the process

of roasting. Hollway's process ought to have shown that, if oxygen enough were used, the only fuel required was the sulphur of the ore; the arsenic might be recovered again in the flues. Having got a good furnace, the next thing was what to do with the ore. He had always advocated simple wooden tanks. In the mill he was running at Utah, they tried for some time to put in hydrochloric acid besides the salt; they usually put in sulphate of copper, salt, and some other extraordinary chemicals like those he had mentioned. Then they heated it with wrought-iron pipes; the pans themselves were generally made of wrought iron, with a flat basis of cast iron set with dies, and the muller was worked round on their lid shoes, all these being of cast iron. The most extraordinary fact came out. They got an enormous per-centage of the contents of the ore up to 93 per cent. in actual practice, and they got the silver extraordinarily pure; but, unfortunately, every bit of the wrought iron about the place began to yield to the chemical action. The silver was deposited, but it was at the expense of the pans and the pipes; they had to give up the process, unless they could constantly replace them, which was not easy in the mountains. However, an intelligent examination showed that you did not want an iron pan; you did want an iron muller, shoes, and dies, which you expect to wear out; but cast iron was worn much more slowly than wrought iron, and the pan itself could be made of wood and hooped round. In that case you would get all the chemical conditions fulfilled; what wear took place of the mullers and dies, would contribute a fine powdered iron to cause the chemical combination sought.

This question of the humid process had been known to everybody connected with mining for many years, but up to 1871 or 1872, they did not give such satisfactory results as were sought, of about 46 to 60 per cent. of the metal in the ore. And he believed he was the first who ever put out anything like 26 per cent. of the metal contained. He took out a patent at the time, but it was hard for one man to fight these things. Unfortunately, everybody tried to make use of it without the knowledge which alone could make it useful. They did it inefficiently, each man taking what he had heard of, and thinking he was very wise, and that he had saved the royalty, the effect being that he made a mess of it to the extent of pounds, where he would only have had to pay shillings. This was a great misfortune, largely due to the state of our Patent-law. With regard to the management of mines, he should have been very glad if he could have run a tunnel in, when he had no hope of getting anything, on tribute; but you could not do it. The men must be sure of their pay, or they would drop their tools directly. You could not sink a shaft, you could not run a level, unless in tolerably rich ore, on tribute. It was usual to let the work on tribute when you had ore, and he always did it; in fact, it had never been the practice amongst miners in Cornwall to do anything else, and all managers of mines were too glad to adopt it when they could. They generally took a stop of which they had not a very good opinion, and said to a man, "We cannot tell what this will give; will you go into a little speculation?" A poor man could not speculate much, but sometimes he said, "I will risk it if you will set it to me at a decent rate; I don't mind taking it with a partner or two." In that way you got tribute work done, to the great advantage of the men sometimes, but at others to the great advantage of the miner; but it was a speculation, and miners could not always afford to go in for that sort of thing. As regards the interest every man took in the mine, he thought a manager's interest was very strongly secured by his pay, because if the mine did not go on and prosper he knew very well it would come to an end, and there would be no more pay for him; it was true some managers did not get paid at all whether the mine prospered or not. He had an assayer retained to assay constantly, or to look at his tools, to

study new processes when there was no assaying to do. How could he ask him to work on tribute; you must have *employees*, if only the blacksmith to sharpen the tools, and there would be some day when there would be no tools to sharpen, and you could not send him away. It had been said that the dividend of steamship companies lay in their coal bunkers, and so the question of whether a mine paid a dividend or not lay in making every ton of rock pay as it came out, if possible. That was what he would really impress on everybody connected with gold mining in India, to see that there was no excuse made for anything thrown away. The assayer ought to be a thoroughly trustworthy man, and should assay what went away as well as what came out. If he did not know everything in the rock and what ought to come out of it, he was not worthy the name. When that was done, mines would prosper. There were no doubt many obstacles. Everybody engaged in mining as they did in tallow, sugar, or anything else, but it must always remain a speculation, for he never could discover that any miner could see beyond the length of his pick. Still a great deal of capital would be usefully employed in mining, and to show how largely that was not the case at present, he would state exactly what had occurred in California. Several millions sterling had come out of those mines, but if you took from Professor Raymond, or anybody else, the quantities of shafts sunk and branches and tunnels driven, it would be found that rather more had been put into the ground in the shape of labour than came out of it altogether in the shape of gold and silver, but it had enriched the country, and gave an outlet for agricultural progress, and encouraged the people to come in and settle, and did a great deal of good in many bye-ways, irrespective of the curious balance of what he had spoken. All over the world you will find the same condition of things. If you took the quantity of paying mines, and set against them the quantity of work done which did not pay, it gave about a balance. There had been a recent discovery which promised something, which he might perhaps advert to as a specimen of an idea cropping out in a new shape. A chemist in Paris had recently patented a discovery by which he proposed to get out, without roasting, from ores containing sulphur and arsenic in large quantities, all the gold and silver—not the copper; and he claimed that he had taken out, from the residue of the Tharsis Company, more gold than they ever knew was in it. He said he used the perchloride of mercury largely, instead of quicksilver, in the grinding process, which he conducted in iron pans, and he used it in salt water. He got iron, chlorine, mercury, and some metals in combination in salt water. He had no doubt that some such effect as he claimed would be produced, simply because that was exactly what they did, in a rough way, in the Washoe process. They put in sulphate of copper and salt; the sulphuric acid left the copper, combined with the salt, to form hydrochloric acid; they had iron pans, so that they were in fact fulfilling the conditions under which per-chloride of mercury could be made, although nobody out there had any idea that that was the manner in which it was done. They all said it was something to do with the nascent copper, or some other wonderful arrangement, and they never sought for the chlorination of this process, considered why it was important, or examined how far the chlorination was carried, because both gold and silver could be carried away in a perfectly clear fluid, and the very water thrown away might, under such conditions, contain as much silver and gold as you were crediting the takings with. When his brother was head of the Geological Survey in Australia, he told him that in mercury troughs at the bottom of blankets he had often found crystals of gold much larger than could have passed through the gratings, showing that there was a formation there, owing to some galvanic action, which deposited the gold in crystals. If that were the case,

easily see how a good deal of gold and silver lost without its being suspected. If this man had found out the way to get at the silver without roasting first, it would save a lot of expenditure, and in such a way as to lead true chemical reactions which took place, he has done an immense deal more for miners than one in his recollection by anyone else.

Secretary said it would be interesting if Mr. Lock more information about the sodium amalgam, which he had alluded to, and which he had discovered by Mr. Crookes. The tone of the matter seemed to be in favour of mechanical rather than chemical methods; but it would be interesting to have any knowledge of this process on a large scale what was his opinion of it.

Admiral Selwyn said the process referred to had been used in California, and was now rather dis-

credited. Secretary said one of the objections mentioned was the fact of this process taking up a lot of space. That could be readily understood, for amalgamation would coat many metals; it would give a nice clean coat to quite dirty iron, but it was not sure whether experiments in this direction had been made by Mr. Crookes, but he knew they had been made by Mr. Bolas. It had been suggested that zinc might be very useful for the amalgamation. The zinc plates in ordinary electric batteries, did not know if anything had been done in that direction, but he might refer, as likely to interest the members, was the reference to Plattner's process, which recalled to his mind a process in the last volume of Dr. Percy's great work, in which he referred to the very beautiful process known as the Plattner process for the purification of brittle gold and silver. This, as Dr. Percy mentioned, was a process that the Society as long ago as 1840, by Mr. Selwyn, in conjunction with the then Secretary, Mr. Adam, had produced practically pure gold from a mixture of gold, silver, copper, and other metals, by passing a stream of chlorine gas over the metals in a state of fusion. This process was now used by the Mint for the purification of gold; and if any member within the scope of the paper, was interested in showing what had been done by the Society in this direction.

Admiral Selwyn, being called upon, said he was not prepared to speak, but he should be glad to show his new machine, which he hoped would be finished in time to show to any one interested in the matter.

Admiral Selwyn remarked that Plattner's process was in use at La Oroya, in Mexico, but the objection to it was that it took twelve hours for a ton of ore, and you could not conduct mining processes in this way. It was a beautiful chemical process, but did not work practically on a large scale.

Admiral Selwyn said he had been engaged for several years in mining in Australia, and whilst there paid great attention to perfecting the operation by means of stamps, and all he had seen, he thought there was nothing like it, either for speed or the fine pulverisation of the ore. Admiral Selwyn said he thought it good work to have a stamp-head per stamp per day; and it was without a Blake or any other crusher, and was sent out through a grating of between 300 and 400 to the square inch. The stamp-heads weighed and the stone was put in as large as it would go for copper - as large as one's head. At first they were troubled to keep down the splash, but at last they had a plan of making the water keep its own level, and by that means they worked the stamps dry. He did not agree with Mr. Lock that the gratings should be back and front; it was not, as the same effect could be produced by

using a little more water. If the outlet in front were 12 inches by the width of the stamping-box, you would get it all out. The foundations could not be too solid; and curiously enough, he had found that where water would not go, gold would, for in taking up old stamp bottoms, he had found gold where it was perfectly dry. For amalgamation they used a cradle with a circular back, in which they put the quicksilver, with a small one in front, and the speed was regulated so as just to keep the stuff lively. The action of sand upon crushed quartz, with the quicksilver in water was to give a roughness to the gold, so that the quicksilver could lay hold of it, which it would not do under other circumstances. In practice they never, except from some careless starting of the stamps too quickly, found any quicksilver in the front part of the cradle. Some years ago he was engaged on a gold, copper, silver, and lead mine in North Wales, and put up some machinery there, of a very substantial character. He would show a sample of the lead, and he had a stone now which contained visible gold, copper, and lead, and several other metals. Of course sulphur was present, and arsenic too. The mechanical mercury process there was greatly interfered with, by the great number of metals, which made it difficult to keep the cradles sufficiently lively; lead was very heavy, and it was necessary to adopt an extra mechanical process to keep it from stagnating. For several months he was at work on this mine, and the quicksilver he lost was only a very few ounces out of the 350 lbs. in use, which was practically equivalent to no loss at all, when you remembered that you could not pour mercury from one vessel to another without losing some. The lead contained a considerable quantity of silver, but the company was anxious to make it a gold mine, and nothing else, which he thought was a mistake. The other day he had a new crusher brought to his notice, which seemed very good. The objection to Blake's crusher was that the moving part was worked by an eccentric; in the new machine this was replaced by a crank and lever, the friction being reduced one-half. If such a machine were used, or stamps such as he should suggest, weighing about 700 lbs., at least four or four and a-half tons would be crushed per stamp head per twenty-four hours. You could not have the stuff put into the stamps too fine, because you got a greater effect. If you put a 4-inch stone under a stamp which lifted 11 inches, you only got a 7-inch fall, whereas if the stuff was not larger than an inch, you got a 10-inch fall, and, of course, the further the fall, the greater the effect. It was very important that the best machinery should always be put up. He quite sympathised with Mr. Smedley's idea about working on tribute, but practically in many cases it was impossible. There were shafts to be sunk, adits to be driven, and so on, which men would not work at on tribute. If you got a payable ore, very likely men would take it on tribute, but not otherwise. He had known many men who would work for a time on a mine, then go to work for themselves, and when they had emptied their pockets, they would go back and work at the mine. If you could get first-rate machinery, and pay men to work it, they would be quite sufficient inducement without any tribute.

Mr. Sholl said that Mr. Lock had so thoroughly exhausted the subject of modern gold mining in his able paper, that there was little left to be said, but he should like to make a few remarks on the important question of stamping the minerals. He was of opinion that the correct principle of disintegrating any minerals containing particles of varying densities, was by imparting rapid and elastic blows, and by using a sufficient amount of water to get rid of the stamped stuff, the instant it was ready to pass the screens. The diagram of his stamping-machine on the wall showed it to be a modified steam-hammer. If, however, it were a steam-

hammer, it would be the very worst possible machine for stamping ores that could be used, inasmuch as a dead blow would smash the mineral (pyrites) and gold in a manner that would be quite fatal to the latter. The modification consists in the reaction of compressed air in chambers above and below the piston taken in, and expelled through the holes, which cushions the blow at every stroke, and renders it thoroughly elastic in its character, and especially adapted for dealing with materials of varying densities, as at speed any known mineral (including emery stone), must succumb, although still retaining the elastic blow in its perfection, as the harder the blow, the more perfect the cushion. The volume of water required per head for ordinary American quarts is about 400 gallons per hour for each pneumatic head. The guaranteed capacity of these stamps is about 10 tons of hard gold quarts per 24 hours through screens 400 holes to the inch, and with two heads in one coffer about 16 tons. Objections have been raised to the supposed heating of the air by compression and consequent loss, but the fact is, that the air is not heated at all, because the outside of the pneumatic supply is constantly under the influence of cold running water, which ultimately runs into the coffer.

Mr. Henty said Mr. Lock, the other evening, explained the chemical combination of gold in iron pyrites, but it was always considered to be a mechanical mixture, not a chemical combination. It was also thought that there were no ores of gold. He had just come from America, and had a specimen of telluride of gold from Boulder County. He did not wish to say anything in favour of American mining, except that it was a large field, and that there were a great number of Cornish miners in America. He was glad to hear of the Indian gold fields, and hoped they would turn out successful. They would probably be worked under very different circumstances from those which formerly existed, when the mines were originally discovered. There was now a great deal of scientific knowledge brought to bear on the matter, which would facilitate the proper working of the ores and the extraction of the metal when found in connection with iron and arsenical pyrites. Allusion had been made to low grade minerals, and he quite agreed that many mines had become very profitable, when they were not successful at first, simply by putting up machinery, which enabled them to concentrate and extract the gold from ore which otherwise was not fit for the market. A mine was generally in an out-of-the-way place, far from the facilities one could desire. The first requisite to success was to have a manager really competent in every respect; and a man educated to his profession, who could combine theory and practice, was the best man. One of the first considerations in machinery was portability. Just now it was a question between stamps of various kinds; but it must be admitted that, wherever stamps were employed, they were more efficient if a crusher were used in connection with them. Most mines under companies were worked under contract work, but those owned by private individuals were generally worked under a lease, which was similar to the tribute system. He had known miners start when they first came out, and work for a company, and when they had made a little money their great desire was to find a place where the rock showed traces of mineral, and try to make money on a lease. But, where a company owned a mine, until they had proved the value of it, it was not practicable in the first place, and in the second place it would not be justified in putting men to work on lease in a mine, near to other mines worked under contract. They might be honest men, but it was not right to put temptation in the way even of honest men. There were large quantities of rich ore lying about, as a big blast would bring down two or three tons at a time. Pieces of ore might easily fall out of the bank

or skip, and there was a temptation to the men to take them in their pockets. The mineral was so throughout the district, that it would be impossible to say what mine the stolen piece came from. The men he produced was very rich, containing for 100 ounces of gold to the ton, and a considerable quantity of silver. A piece broken off the ore stone he had put into a muffle, heated it to the telluride, and it left the gold thickly covered on the stone.

Dr. Carter Blake said he was at the gold in Central America for some time, 13 or 14 years. The Chairman must remember the fact that there is Central America a sort of savages who employ the extraction of gold a much more simple method than those which had been described; who employ the *crustro* method, which was simply the rotation of large stones of coarse sandstone, a system most barbarous, imperfect, and irregular. But what did that system do? It produced a percentage of gold than some of the most exact processes which had been since. These mines had been worked by the Spaniards by these wretched Indians, to a productive and an extremely small expense for labour. Some say that the saving produced was simply a question of labour; others might say that the expense of sand of European mills and machinery was a heavy, and that was why they had not in some experience in Central America led him of the story in Walton's "Angles," where a ragged boy, with a crooked pin at the end of a leaded a bigger fish than the elaborate angler; the most expensive fishing-rod and apparatus. was one question he should like to ask practically being entirely ignorant on the subject himself where the miners in Central America got the for amalgamation before the Spanish came. There was evidence that these gold mines were but there was no evidence whatever that the use of mercury existed amongst these Indians.

Mr. Smedley asked leave to explain, with reference to his suggestion for introducing the tribute system he did not mean it to apply to dead work, sinking shafts, running tunnels, or driving as to the delicate manipulation of the quarts of mined, that is, to the crushing, amalgamation, reduction of the ore into bar gold, and to the subsequent classifying and concentration of the tailings.

The Chairman thought there had been a little censure in the description arising from the title paper, which was in reality a paper of a practical character, dealing mainly with the processes. He had not, at the present moment, any advantage possessed by Admiral Selwyn and other gentlemen, of being practically connected with these matters, but he might nevertheless be of use, as he had had that intervention in form and it was sometimes useful to bring to bear questions the evidence of one who might, call himself an interested bystander. The all apt, in looking at new inventions, they were absolutely new, whereas further showed, as Mr. Truman Wood had pointed out that it was but the development of an idea which had been worked at years before. Beyond his own experience, which was not very small, he had acquaintance with the history of the subject, knew that, whether with regard to the mechanical or the chemical part, it had in all times occupied the attention of men of very great knowledge and ability. Evidence they had had that even from many men as to the way in which they had applied themselves to the subject, was only a repetition of what had been done in times long past. There were, however,

ren apart from those to which Mr. Henty had  
 It was easy in the laboratory to deal with  
 tion of reduction; but the real fact was, that  
 hardly a district or place in which there was  
 a special characteristic in the mineral, and  
 still greater difficulties in reduction works,  
 received the ores of various districts. Mining  
 as were begun, and the reduction was carried  
 the best possible way, and it was, perhaps, only  
 the end of the time that the little chemical  
 was discovered which enabled that descrip-  
 tion to be successfully dealt with. With regard  
 to, for instance, in some cases, the very roast-  
 ing had the effect of impeding the abstraction  
 metal. In some cases you exhausted the whole  
 mine before you found out what ought to be  
 done. This was a difficulty for which managers  
 were by no means to be blamed. The truth  
 Admiral Selwyn had said, that mining must be  
 a speculation. They must not, however, sup-  
 while mining was a speculation, and while they  
 acted to them such figures as those mentioned  
 which he knew to be accurate—that that  
 representation of the condition of mining  
 not impossible to get at the true facts, con-  
 sider their economic conditions. They saw, for  
 50,000 put down for the capital of a mine;  
 me to an end, and it was assumed that, as  
 was paid, there was a dead loss of £50,000;  
 omical fact, there was, perhaps, no £50,000  
 some cases half of that had been put down  
 sideration for the purchase of the mine,  
 e in other ways of the same kind, and  
 no efficient disposal of capital. Another  
 b happened in mining, over and over  
 his: three sets of companies, or individuals,  
 ne, each sustained a loss, each turned over  
 ry to its successor, and the last one made it  
 e case of the Devon Consuls, which, with a  
 1,000, paid a £500 dividend on each £1  
 must get at the real effectual economical  
 ascertain the real facts. Still, mining was  
 a; and if it did not answer the purposes of  
 it would not be carried on. When it  
 mines were suspended for a time, and  
 the figures became fallacious. It was true  
 inducement to gambling, and the miner  
 mber in mining, and sometimes, as in South  
 gambler outside the mine, instead of follow-  
 cess which had been described of going and  
 wages, and then having a turn at tribute,  
 g back to wages again, it too often happened  
 tries that, when he had made money in  
 too often lost it in cock-fighting, monte, or  
 form of gambling. It was a spirit of enter-  
 induced men to follow up mining, but,  
 could maintain themselves by it, they  
 only not pursue it. It was needless to say  
 ore on the question of tribute; Mr. Smedley  
 ed what he meant by it, and it was a system  
 in Cornwall, and all over the world. In  
 was no part of mining which was not a  
 t of centuries of experience; in some cases,  
 from the times of the Romans, or their pre-  
 There were so many points which affected  
 ion, and which it would be desirable, if they  
 follow out; but, unfortunately, they had not.  
 rd to per-centage of gold, that was no  
 criterion. It might give a greater net  
 get out 75 per cent. than 80, for instance.  
 However, one point to be borne in mind in dis-  
 subject, and that was the great distinction  
 operations of an individual and a company,  
 had told them how an individual did in  
 and in the same circumstances the same was  
 small, and other countries. When you came  
 y it was a totally different affair. A com-

pany could never look after its affairs like an individual.  
 It must have checks of various kinds. As Admiral  
 Selwyn had pointed out, you must have an assayer—  
 you must go on feeling your way by his help; but an  
 individual who had a small working did not burden  
 himself with an assayer; he had a good piece of ground,  
 and worked it out in the best way he could. The  
 position of a company was totally different. It must  
 have, apart from the dead work of the mine, a great  
 deal of dead work in the shape of administration. The  
 same forms must be carried out in the beginning before  
 it was ascertained whether the company would pay or no.  
 It mattered not what it was, in any mercantile operation,  
 wherever there was a number of partners, a totally  
 different system of checks was required to those which  
 would do in individual undertakings. Those things  
 were open to abuse, and the only remedy could be what  
 was pointed out by Mr. Lock, Admiral Selwyn, and  
 others, the application of intelligence, and looking to  
 the character and integrity of those employed. He  
 thought he could answer the question put by Dr. Carter  
 Blake, as to where the mercury came from before the  
 Spaniards went to South America; the only answer  
 being that no mercury was employed at all, and that con-  
 stituted the difference between the old system of gold  
 working and that inaugurated by the Spaniards. Under  
 the old workings, men could only work for gold  
 where it was visible, and where it could be got  
 at mechanically; they began by working up ingots,  
 and then worked up any rich ores of which there was  
 an outcrop. The lesson to be learnt from these things  
 was, that under the proper application of refined pro-  
 cesses they were liable to get a much larger amount of  
 gold in the gross than could be obtained by the old and  
 ruder methods. It was almost inconceivable the small  
 amount of gold per ton with which a mine could be  
 made to pay. It was not necessary to make any  
 defence of Mr. Lock in treating with the mechanical  
 conditions, because they must necessarily precede the  
 chemical or metallurgical treatment. You must first  
 get out your ore, and put it in the state for chemical  
 treatment. In conclusion, he proposed a cordial vote  
 of thanks to Mr. Lock for the very valuable paper he  
 had brought forward.

The vote of thanks having been carried unanimously,

Mr. Lock replied on the whole discussion. He said  
 that at the last meeting a gentleman asked him a  
 question about gold mining in Transylvania, and if he  
 could explain why it was not profitable to the Govern-  
 ment. He could not answer that very fully, because  
 the Government only worked one mine there. Of  
 Hungarian gold mines generally, and Transylvanian in  
 particular, he had a very high opinion. There was  
 no fault with the mines, the faults lay in the defi-  
 ciency of capital to work them, and in the treatment of  
 the mineral for the extraction of the gold. But many of  
 the private mines did pay, and the Government mine  
 also paid a considerable amount. There was no doubt  
 they could all be made to pay much more if properly  
 worked with sufficient capital. He agreed with Mr.  
 Smedley, that they wanted a better system of managing  
 most of the gold mines in which English capital is in-  
 vested. He was disappointed that Mr. Fisher had  
 not said more about his stamping mill, because it  
 was a new idea, only brought under his notice  
 within the last few days, and there were certain  
 parts of it he liked very much, though there were  
 others he did not like at all. It seemed to him  
 that the speed being 500 or 600 blows a minute  
 was a step in the right direction, but its having  
 no cushion, and having a dead blow, seemed to him at  
 present a fatal objection. Again there seemed no  
 means provided in it of letting the free gold, after it  
 was once crushed out of the ore, get into some place  
 where it would not be smashed. He was in hopes they  
 would have had many persons there who would have  
 gone into the question of fine stamping versus roast-

ing, because there was a great deal to be learnt on the subject, and the sooner they knocked their heads together and got some information out of them, the better. He thought that Mr. Fisher's machine was more fit for dry crushing, which was another point not touched upon, how far dry crushing was superior to wet crushing. He exhibited a tracing of Walworth's aspirator, which was being adapted to extract the material out of the coffer as fast as it was stamped, separating it by gravitation in air instead of in water. All these points had to be considered and discussed. He had with him three samples of crushed ore, one of which had passed through a grating of 900 holes to the inch, another through a grating of 2,916 holes to the inch, and the third through a grating of 4,624 holes to the inch. He should like some of the gentlemen present to take some of the latter powders and rub them in the palms of their hands, when it would feel just like fine flour. He must thank Admiral Selwyn for the admirable manner in which he had treated the subject, and was sure he would not object to his differing from him in several important points. The Admiral told them a great deal about America and American systems. He (Mr. Lock) cared only about the process of treating ores, whether it came from America, Australia, or anywhere else; he simply looked at the system with practical common sense, to see whether there was anything in it or not. Of course, he was liable to error, but he endeavoured to exercise his common sense, and he must say it did not seem to him common sense to crush gold and all the material as fine as flour, and then be at all surprised that the gold went away in the water. With regard to the different processes which Admiral Selwyn had touched upon, they were used for the treatment of ores containing copper, silver, lead, and a variety of other things, whilst his paper dealt only with gold. He did not touch on the Washoe process, because it was essentially a silver process.

Admiral Selwyn said it was available for gold.

Mr. Lock said it was available only for a silver ore containing gold, in his opinion. Admiral Selwyn had said that the Plattner process had been abandoned in America. The same thing had occurred also in Australia, because it did not answer. It answered admirably in Germany, but there was a peculiar combination of circumstances which made it answer there. That was a difficulty with which one had to deal—the varying conditions in different countries. What he had striven to do was to point out a simple method, which was being proved by practice to be successful. This was shown by assaying the tailings every hour or two hours to see how much was going away. That was the only test, but the extraordinary thing was he could not get anybody in America to give him an assay of the tailings. It did not seem to him there were any assays made.

Admiral Selwyn said he had been superintendent of mines out there, where it was done constantly every two hours; and he did not know a single decent mill in Western America where it was not done.

Mr. Lock said he could never get them. Many gentlemen gave him their processes; but when he asked where they had been tried, and the result, and what were the assays of the tailings, he never could get such assays. It was not much advantage assaying the ore before treatment, because the amount consisted of that which you got out, and that which went away; all you wanted to know was what went away; and if over five or six per cent. went away, there was something radically wrong. Admiral Selwyn told him that there they only got out 70 or 80 per cent., and that exactly bore out what Skidmore, Hague, Raymond, and everybody else in America had said, they did not get the gold out within about 25 to 30 per cent. Now, in Australia, by the method which he had attempted to describe, only

five to seven per cent. was left in the tailings. regard to this chloridising process, it could not exist in every country, because the materials must exist; there might be a want of fuel and of Australia it was found that using salt was for auriferous copper ores. Admiral Selwyn about a wonderful process for getting gold material which did not show gold by assay. he happened to be talking the other day to most eminent practical metallurgists who have thousands of tons of similar ore, and in speaking different patents and new ideas, allusion was one of a similar character, of which his friend said, "Ah, yes, that is a wonderful process, they get a-half ounces of gold out of a ton of stuff, if by assaying, no gold could be found." "How in the world did they do that; surely it be a swindle." "No," said his friend, "not; it was done honestly enough. They it over amalgamated copper plates, and these had been used not long before for some very material; some of the gold from the rich material stuck on the plates, and then, when they came to the plates off, they found the gold; and of very small quantity in an experiment, makes a large quantity per ton, and thus they manage to get one and a-half ounces of gold out of ore contained not one grain." He merely mentioned show that you must not always believe a thing wonderful success because an experiment or two made with it, and the assay turned out well. only by treating many hundreds or thousands of tons any process could be thoroughly tested. The process had attempted to explain had been used for millions of tons, and had proved successful. That was the question with any process, would it stand the test—was it simplest and the best? With regard to Mr. suggestion, that only one screen was necessary, thought that point had been already met, and it required further notice. Sodium amalgam had been tried in Australia, and had not been found successful. There was a great deal in it no doubt, but it was a ticklish thing to play with, and unless you had educated men than at present, it would not much into use, though in course of time more might be done with it. The result which he drew from the discussion was that the subject was not half exhausted. What they wanted in this country was a Gold Institute similar to the Iron and Steel Institute; a place where papers could be read and discussions take place, which every man who had an idea on the subject get it discussed, and thus very soon find out if he was correct or not. He believed that such an institute would have that effect, and gold mining would have an absolutely fresh start, and you would get capital invested, because it would be better understood. As far as he was concerned, he was ready to hand over to such a society all his notes and papers, and he thought he could say he had many books which were not obtainable in England if others would come forward and do the same. They might get up something really practically. With regard to the improved stamps, Mr. Lock did not seem to approve much of them, but they differed from him. He did not say they were the best for gold mining at the present moment, but with alterations, they certainly were a step in the right direction. He happened to have some gold coming over from Asia Minor, and if Mr. Fisher Sholl, or any other gentleman liked to have it put in their machines, and let people come to see if they could work so as to test their capabilities, he should be very happy to let them have it. In conclusion, he thanked the meeting for the attention they had given to the subject.

The Chairman said in the usual course of the duty would have been finished, but Mr. Lock

out a proposition which he was sure his former members on the Council would be willing to support. He had often urged on his old friends in the past to found a Copper Institute, and with regard to a Silver Institute there could be no question as to its being very valuable. They could not expect members at first, and there would be difficulties at first, but if Mr. Lock would address a letter to the effect that he was sure they would lend him assistance, in the early stages would be of service. They would give him the use of rooms, and save preliminary expenses in various directions. In that way, as Mr. Wood had jogged his memory, many valuations during the last 100 years had been made under the fostering care of the Society of Arts, which were still at work, doing a great deal of

## MEETINGS OF THE SOCIETY.

### TELEVENTH ORDINARY MEETING.

January 26th, 1881; ROBERT  
 C.B., Vice-President of the Society,

Following candidates were proposed for  
 members of the Society:—

Clayton, 64, Portland-place, W.  
 Barrow-in-Furness.  
 L. M., 46, Grosvenor-street, W.  
 Tovil-house, Maidstone.  
 Evelyn, 4, Breakspears-road, Brockley.  
 M., Q.C., 1, Plowden-buildings, Temple,  
 George, jun., Beaconsfield-house, Godolphin-

James, 18, Urswick-road, Lower Clapton,  
 hall, Hackney.  
 Maxwell, F.C.S., Cotford, Oakhill-road,

imus, Castle-house, 44, Mildmay-grove,  
 Mark, N.  
 Joseph, Hartsholme-hall, Lincoln, and  
 Works, Lincoln.

George S. V., The Westminster College of

McCormick, F.R.G.S., Hesketh-house, 54,  
 street, Russell square, W.C.

Following candidates were balloted for, and  
 members of the Society:—

Antonius, 87, Seymour-street, Hyde-pk., W.  
 Ball, F.R.G.S., Carisbrooke-lodge, St.  
 d East, Putney.

Edward, Streatham-hill.

, 88, Richmond-road, Bayswater, W.  
 Richard William, 18, Cookspur-street, S.W.  
 Peter, M.D., Ellora-villa, Silverhill, St.  
 n-Sea.

Macraugh, The Warren, Torrington, Devon.  
 Tennyson, Wigan.

William Kennedy, 8, Gloucester-square,  
 W.

John Barnwell, The Grove, Esher, Surrey.

Martin, 117, Leadenhall-street, E.C.

de Louis, Burton-in-Lonsdale, Yorkshire.

Robert Alleyne, South-lodge, Cockermouth,

James Phillips, Drapers'-hall, Throgmorton-

## SUGGESTIONS FOR PREVENTING LONDON SMOKE, AND MAKING IT COMMERCIALY AVAILABLE.

By W. D. Scott-Moncrieff, C.E., F.R.S.S.A.

It is sometimes difficult to account for sudden movements of popular opinion. When once they begin, an element of momentum seems to take the place of the previous inertia, and the new form of social force appears frequently to be directly proportionate to the one which preceded it. We are now in the midst of one of these movements of opinion that is not difficult to account for. The interest which at present attaches to the question of how best to obtain the blessings of an uncontaminated atmosphere, has arisen out of a state of things with regard to smoke and fog, that is recognised as dangerous to the whole community. The work of relating the means to the end has commenced in earnest, and there is every likelihood that, before long, the public will be put in possession of information as to how the problem is most likely to be solved.

Some apology is, perhaps, necessary on my part to those who are at present exerting themselves as specialists in this field of inquiry, for not having laid my proposals before them to the exclusion of other channels. I am sure, however, that if any of these gentlemen were in my place, they would have thought twice before rejecting so favourable an opportunity as the one which has been presented to me. The Society of Arts has already identified itself with this important subject. I trust that further facts and information may be brought to light by this additional discussion, and that they may prove useful to the committees whose praiseworthy efforts are, at present, being exerted for the public good.

The present position of the question renders it far from easy to know how best to deal with it before a scientific audience, who are well informed. Materials which were important contributions a few months ago, have already been assimilated, and no longer lend themselves to the further elucidation of the subject. I trust, therefore, I may be permitted to confine myself to the special scheme which I propose, and I need not say with what pleasure it is that I do so, when I tell you that, although it has occupied my thoughts for years, this is the first occasion upon which I have addressed an audience on the subject.

I wish, first of all, to attempt to make clear to you in a few words what is the present aspect of the question as regards the methods and apparatus employed.

The classification of the methods may be arranged as follows:—

1. Burning bituminous coal at a single operation, by exposing it to the heat of the fuel previously ignited. It is unnecessary to say that this method embraces nearly the whole of the domestic consumption of Great Britain, and a great part of the commercial consumption as well.

2. Separating the gas from a cheap quality of coal, heating it in an apparatus known as a regenerator, and using it without the solid residue.

3. Separating the gas from the coal at a comparatively low temperature, adding the partly coked residue of a previous charge to the fuel in the furnace, and passing the gas through the burning mass.

4. Using coke as a basis, and passing gas through the fuel as a means of supporting its combustion, both coke and gas having been obtained from a gas company.

5. Using fuel from which a certain proportion of gas has been extracted, which is the special subject of the present paper.

As regards the apparatus, it naturally follows the classification of methods or systems, and would far exceed the compass of this paper to describe in any detail. It will be well, however, for me to say something of the more familiar appliances which are in every-day use, and to remind you of certain fundamental principles that are common to the whole of them. As you are all well aware, the combustion of bituminous coal depends upon the combination of certain gases, and of carbon and oxygen at a high temperature. It is also familiar to you all, that the oxygen necessary for this combustion is obtained from the atmosphere we live in. One necessary feature of the process is the creation of a draught, which is obtained, as you all are aware, by the action of a heated column of air in a shaft or chimney. But this invariable accompaniment of combustion is, in the nature of things, associated with a movement, not only of the air, but of the gaseous elements of the fuel, and it is almost inconceivable that the necessary quantities of oxygen can be obtained without this element of rapid movement. The question comes to be then, whether or not the mean velocity of the air and gases necessary to supply the oxygen, is compatible with the time that must elapse in order to obtain the necessary chemical combinations at the point of sufficient temperatures, which is in the body of the fire itself.

Now in the case of freshly added bituminous fuel placed on the top of a burning mass, it is quite certain that the conditions of a draught are inconsistent with complete combustion; and this brings us to a consideration whether or not it is possible to consume bituminous coal perfectly at a single operation, and leads to doubt as to the possibility of using the first method successfully in any apparatus, however ingeniously it may be devised for the purpose. Certain proposed processes are sometimes so inconsistent with the operation of invariable natural laws, that a conclusion on the subject of their failure has the

certainty of a complete induction. If depended upon its success on the water to run up hill, as in the case of London house drains, we should be sure of its failure. The matter, as regards combustion of fuel at one operation, in this elementary category, but, it is very near to being so.

I am sure many present will sympathize in the great difficulty of making clear matters that do not contain within them the elements of a complete induction may be so far complete, as regards that the mind is forced to a definition, but the discrepancies may, nevertheless, very elements which go to form a problem in another direction. I do not know of any way of illustrating my meaning than to refer to several well-known fields of investigation. At one time, seemed to be altogether different, which have become gradually closed by the advance of scientific knowledge. From the early days of steam locomotion, there have been many persons who thought it was on the part of certain engineers to go against the principle of the atmosphere. It must have appeared to them that to predict the failure of science in the whilst anticipating its triumphs in the future, yet, I have no doubt, that men did not at that time what was practically a compromise in their own minds, however difficult it was to convey their arguments conclusively. Now, I do not know of any problem which gives a greater promise of a solution than the burning of an ordinary piece of coal. The elements of combustion are available, but, up to a certain point, they do not seem ready to a partial solution of the problem. Nothing is more easy than to get a fire on an ordinary grate, and nothing is more difficult than to get it to burn in such a way that the products shall escape up the chimney. The failure of all appliances for all time to attain this object is, therefore, on the face of apparently rash anticipation, and nothing in the scientific aspect of the problem suggests any other conclusion to me than that we are not so much inclined to this opinion as we are to arguments that present themselves as the result of experiments on a small scale, from those which may be gathered from the experience of persons engaged in the use of fuel on a large scale, where the conditions for carrying out complete combustion are not so favourably situated.

Taking the iron trade as a typical example, may say that all experience in the matter of cleanliness and economy is tending towards a total abandonment of the use of bituminous coal at one operation, and towards the use of the blast furnace, which perhaps presents the greatest difficulty in this rule is the blast furnace. The apparatus, which the consumption of fuel is carried out in, would of itself place it in a position as affording peculiar facilities for carrying out an intense and constant temperature, here, however, the operation is, to a great extent, divided, and the utilization of the waste gases for heating the air stove

that, even with all its peculiar advantages, blast is unable to carry out complete combustion at one operation.

is an illustration of a blast furnace of a not improved or modern type, but which is not to show the immense advantage the blast has over anything that one can conceive of our present state of knowledge in respect of domestic appliances. The temperature is not only enough to melt iron, but it is maintained one month's end to another with the skill and industry of trained workmen. The air is not introduced in immense volumes by means of forced blowing-engines, but is heated to a high temperature before it reaches the fuel. The artist, I think, somewhat exaggerated the volumes of air escaping from the mouth of the furnace, but at least shows he was conscious of its presence. Now, as a matter of economy, these gases are utilised in the modern practice of hot-blasting, but if they exist at all under conditions so favourable to complete combustion, what is the use of appliances that burn a few pounds of fuel at a time under the charge of an over-looked housemaid? I am not speaking now of combustion, but only of that fair amount consistent with a smokeless chimney.

In other departments of the iron industry an attempt to consume bituminous coal at one operation is being altogether abandoned. The works of Dr. Siemens, as embodied in his hot-blast furnace, have gone far to bring about a change in the direction of scientific principles, and his gas-furnaces, as now used at Woolwich, are also an illustration of improvement taken place in the same direction. I shall not attempt to speak of these appliances presently, but without saying that arguments drawn from the fact that the scale of the consumption is smaller, will be still more impossible of attainment, I regard the scale of appliances that would alter the head of domestic apparatus, and that the problem of consuming ordinary bituminous coal at one operation will ultimately be solved altogether, but it is beyond all doubt that it will ever be satisfactorily solved. Some years ago, this opinion would have been regarded as unreasonable. I have long been of opinion that it is a sound one, and this is supported, not only by several eminent engineers, among whom I may number Dr. Siemens, but also by the whole tendency of the improvements which have been carried out in great national industries. I believe it to be a theoretical proof; but even if this is not a theoretical proof, I think I am justified in pointing out the condition of our large towns as a result of the failure of existing appliances. The vast amount of invention which has been expended upon the problem of the complete combustion of bituminous coal at one operation is to be accounted for, and when it is considered that the appliances have ever been altogether inadequate, I think there is a strong *prima facie* case for pointing out against the practicability of the hot-blast. If I may be allowed to put the argument in the form of a syllogism, with

regard to domestic hearths, I might say all bituminous coal requires a high temperature steadily maintained for its complete combustion. Domestic fires are incapable of producing a high temperature steadily maintained, therefore domestic fires are unfit for the complete combustion of bituminous coal. To hold an opposite opinion with regard to the element of temperature is inconsistent with the facts, and to insist on the high temperature being continually maintained is to deprive every citizen of his right to allow his fire to go down when the heat he obtains from it has become excessive. I might quote many authorities in support of these opinions. Even in the case of steam-boilers, where skilled labour is available, and where a high temperature, evenly maintained, is an important point, Dr. Angus Smith shows clearly that it is heat that is required for the complete combustion of the fuel, and that the supply of air in sufficient quantities is comparatively easy. I will suppose the case of an absolutely perfect domestic appliance for the combustion of bituminous coal, and I will ask the inventor of it where the heat has to come from that is essential to the process, when the fire has been allowed to go almost out, and the housemaid adds fresh fuel.

So far, I have tried to put the matter before you as regards temperature, but a moment's consideration of the actual process of combustion will, I think, make it equally impossible to escape from the conclusion to which I have come, even as regards the supply of air itself. Burning coals depend for their incandescence upon the passage of air among their exposed surfaces. In an open brazier, it may pass in from all sides, and underneath as well. So far this is a most favourable condition, but as it passes through the burning mass the oxygen is consumed, and it is impossible to insure that the air does not reach some parts of the fuel in an exhausted state. I have here a simple illustration of my meaning. This common paraffin lamp is so arranged that a current of air passes in close contact with the flame from the wick, and the oxygen is consumed in its passage. I will now suppose that this piece of bituminous coal, which I place over the top of the funnel, holds an analogous place to that which it might assume in the most ingeniously constructed stove imaginable, that is to say, some point at which the air, which has already passed through the fire, reaches it exhausted of its oxygen. The temperature of the lamp flame is sufficient to produce an escape of gas, and upon passing my hand over the funnel this is proved by the pungent smell of the gaseous products. Now you will find, that although the gas is escaping, the conditions are altogether inconsistent with combustion of any kind whatever. Upon striking a match, and bringing it near the top of the funnel, you will see that it is instantly extinguished. I now take a piece of smokeless fuel, and place it over the funnel, instead of the piece of coal. It goes without saying that although there is no more chance of combustion in the one case than there is in the other, still no smoke escapes, and, as far as the atmosphere is concerned, no harm is done.

I might multiply arguments indefinitely; but as time is of importance, I must ask even the un-

believing to accept my conclusions in the meantime, and simply point out that if they are right, the idea of adapting domestic hearths to the complete combustion of ordinary bituminous coal may be abandoned at once and for ever. If smoke were like certain gases that burst into flame at a low temperature when they escape into the air, there might be some chance of obtaining a satisfactory result. But the fact that it does not ignite, even in contact with a red-hot piece of iron, shows how temperature, beyond the capacities of an ordinary hearth, is essential to its perfect consumption. I have here a list of the gases contained in ordinary coal:—

	Manchester gas.	Gas as supplied to Houses of Parliament.
Hydrogen .....	52·71	41·71
Marsh gas.....	31·03	41·88
Carbon monoxide.....	4·47	4·98
Olefines .....	11·19	8·72
Nitrogen .....	—	2·71
Carbon dioxide.....	0·58	—
	100·	100·

Now, some of these gases combine with oxygen much more slowly than others, so that some of them, in the case of an apparatus depending upon a draught (and I know of none in the nature of a domestic appliance that does not depend upon a draught), would be half way up the chimney before the combination was complete.

If these conclusions are right, an immense amount of ground is cleared as regards the solution of the problem, because the knowledge of what will be successful is, in nine cases out of ten, arrived at by discovering what cannot be successful in the nature of things. The conclusion means, in other words, either that the use of ordinary bituminous coal must be abandoned altogether, or that some apparatus must be devised for domestic purposes, similar, on a small scale, to those which have been introduced in our great industries, more especially those in the iron trade, to which I have already referred. This brings us to speak of the second and third methods, and I shall do so in as few words as possible. I do not see how these can possibly be carried out, for the simple reason that on the large scale skilled labour and the means of maintaining a constant high temperature are essential features of complete combustion, and neither can possibly be present with any certainty in the case of domestic fires. Dr. Siemens has hit upon an ingenious plan, by which he makes use of the operations of gas companies to separate the operation of combustion, it may be, miles away from the point of domestic use. This is the fourth method I referred to. By burning coke with gas flames burning through it, he avoids the difficulties of separation as regards the consumer, and carries out a scientific system of combustion at the same time. I propose, however, instead of this, to use a modified condition of bituminous coal, and I will try to show the advantages of doing so. It might be presumption on my part to say that I am the discoverer of this sort of fuel, but I may say that, so far as I know, I am the first to bring it into public notice.

First, I may say that, with regard to anthracite coal, if the principle of smokeless fuel is once recognised and enforced, the stone coal will fight

its way, and be of great service, not heating agent, but as a wholesome souper, petition as well. It is as a means of smoke and improving our light that I propose this fifth method, and I shall go on to describe it.

About ten years ago I made a series of experiments upon the separation of the products of combustion which led me to think very highly of a class of fuel to which I refer. I placed a retort in a common Cornish steam boiler, lowering the position of the fire bars, and an apparatus for the distillation of gas from ordinary use, and after some time had I discharged the gaseous contents of the retort into the furnace. In this way I secured complete combustion by a separation into its constituent parts of solid carbon and hydro-carbon products. The semi-coke, separated from this short distillation was smokeless, and I have since discovered by treating it with water when hot, as a means of coke, renders it still more smokeless. I am aware, it is the most perfect fuel I have as it has all the cheerfulness of ordinary coal, none of the disadvantages arising from the use of coke.

I must now ask you to turn your eyes to the present condition of London as regards fuel, and to make an effort to realise how the fuel actually stand. Leaving out of question the fuel which is consumed by the public, I will realise the fact that there are about four million tons of coal consumed in London every year. I can conceive of this more readily, as a man with a base of about 200 yards, built up upon all sides, to the height of the spire of St. Paul's Cathedral. This is what the fuel for the purpose of obtaining heat, is to the surplus coke sold by the gas companies. Bearing this in mind, I must now ask you to realise another quantity—viz., about four million tons—used for the purpose of obtaining heat. This would be represented by a cube of fuel, with a base of about 200 yards, built up to a height of about 200 yards. All this vast quantity is passed through the retorts, and, after a large amount of bad gas has been extracted from it, it is converted into coke. Now, it has entirely escaped the notice of the public, that the gigantic appliances necessary for the one heap of coals on a long extra bed of coke, is capable of extracting a quantity from both heaps of coals, and the extraction, with good results both as regards heat and fuel. The fuel would be similar to the coke, and the illuminating power of London gas approximately doubled, and the aniline, ammonia, and other products of the distillation, must be doubled as well.

To those who may be ready to exclude the vast capital which will be required for this operation, I will now show you that no additional plant is necessary to obtain this result. We will begin by illustration. Supposing one of the gas companies were to begin to-morrow to extract gas from which only 3,000 cubic feet of gas had been extracted per ton. The fuel would be cheap to the consumer at 23s. per ton to start with, the company would recoup

for coal, which we will suppose cost them on an average about 16s. per ton. But, in order to keep up its normal production of gas, so soon as a retort is discharged, it would simply need to be charged again. In this manner gas would be coming away from the retort all day long, just as formerly, with a slight loss of time to be allowed for the additional frequency of the charging. As, however, the gas under the proposed arrangement comes off much more rapidly than under the existing system. The supply at the end of the 24 hours would be in excess of that which is obtained from the long extraction, and in this way less and not more plant would be necessary to give the same quantity in a given time. But instead of bad 12-candle gas, they would have 20 or 24-candle gas to dispose of, with double the quantity of bye-products to the good in addition. What applies to the case of one small factory would of course apply equally to the case combined.

I have already trespassed on your time at considerable length, but as there are no doubt many in the present who prefer an ounce of practice to a hundredweight of theory, I think it well to tell you that my scheme has already been tried out at Woolwich Arsenal when all other methods had failed to supply the establishment with efficient light. When I say my scheme, I say so with an important limitation in this particular case, namely when I went to explain the proposal to Mr. Wallace, who is one of the most scientific gas engineers in the kingdom, I found he had already been in the habit of adopting it. Curiously enough, however, he had never generalised from the facts, and until I pointed out the wide applications of which it was capable, had not thought of it as a means of utilising the smoke of our great cities. During the long winter evenings, the available plant at the Arsenal frequently falls short of the demands that are made upon it. Under ordinary conditions, the supply of 16-candle gas is sufficient for the purpose of supplying light, but if we take quantity of this to be, say, 100 cubic feet per unit of time, then if 20-candle gas were substituted, the quantity of light would be increased proportionately, that is to say from 100 to 125, in the case of photometric measurement. Now, not only is the result obtained, as regards the quality of the light, by simply removing one charge of coals at the end of four hours and substituting a fresh one, but larger quantities of the better gas are obtained, and that for two reasons. First of all, the gas comes off in greater quantities per unit of time on average short extraction than on an average long one; and the fuel used for heating the retorts is greatly superior to ordinary coke, assists the operation still further. In this way, then, the priority of the short extraction is proved in all directions. I have here a few specimens of the L. No. 1 represents an extraction of 3,000 cubic feet per ton; and if it were used in London, this city would be rendered practically smokeless. I must explain, however, that an experimental retort does not give a fair specimen of the fuel. Measurement by the meter is the only method of guessing at the amount of extraction; but this is by no means a satisfactory one; the equable character of the distillation is to say, that the 14 cubic feet of gas which come away from 1 lb. of coal in an experi-

mental retort, although a satisfactory test of the extraction being at the rate of about 3,000 cubic feet per ton, may, nevertheless, have come to a great extent from the outer surface of the sample, leaving the interior both bituminous and smoky. In an ordinary extraction on the large scale, the fuel may be taken as smokeless, and in every way suitable for domestic consumption.

Perhaps, the most pleasant way to conclude this paper would be to draw a picture of the present state of London overcast, filthy, given to fogs, grievous to breathe in, with the London of the future, clear as the tops of the Surrey hills, if the fuel I have been describing were in universal use. I must ask you instead, however, to follow me through a few figures which explain the financial bearing of my scheme upon the community generally.

First, then, as regards capital expenditure, I propose to take advantage of the existing plant of the gas companies. I find they are amply sufficient for the purpose.

Instead of taking 10,000 cubic feet of gas per ton from the coal, I propose to take 3,333 cubic feet, and to pass three times the quantity through the retorts, or any other proportion that may be found most convenient. The result of doing so is startling.

The companies will have double the quantity of by-products they have at present in the shape of tar and ammoniacal liquids; the community will have 24-candle gas instead of 16-candle gas; the fuel resulting from the process will light readily, and it will make a cheerful fire that gives out 20 per cent. more heat than common coal; London would become a smokeless city.

In dealing with the figures, I shall take them roughly, but in such a way that by including a few outlying corporations they could be made absolutely correct.

I take the total annual consumption of coal in London to be 6,000,000 tons. Of this I take 2,000,000 tons to be the annual consumption of the gas companies. The total quantity of fuel used for general purposes I take to be 4,000,000 tons of coal and 1,000,000 of coke sold by the gas companies.

We shall now see what would be the result if we treat the whole of the 6,000,000 tons in the retorts on an extraction of less than three hours, instead of the six hours at present prevailing.

The total quantity of 16-candle gas consumed in London may be taken at 2,000,000,000 cubic feet. This would be at the rate of 3,333 cubic feet per ton upon 6,000,000 tons, the total quantity of coal consumed in London. The residual smokeless fuel would amount to 5,100,000 tons. Of this 1,000,000 tons would be required for the extraction of the gas, leaving 4,100,000 available for the general uses of the community. This has to be compared with the 4,000,000 tons of coal and the 1,000,000 tons of coke already referred to as consumed at present. Now, the smokeless fuel which results from an extraction of 3,333 cubic feet of gas per ton has a heating capacity fully 20 per cent. greater than common coal, and 10 per cent. greater than coke. This gives us the exact equivalents of the 5,000,000 tons of fuel at present in use.

So far the account, as regards the fuel available

for the community balances. We may now deal with the difference in value between 16 and 24-candle gas. As the value of the gas varies directly as its illuminating power, the calculation is very simple. If we take the average price of 16-candle gas to be 3s. 6d. per thousand cubic feet, we shall find the total value of the 20,000,000 consumed in London to be £3,500,000, but as we have by my scheme the same quantity of 24-candle gas, the value will be increased to £5,250,000; here then we have an annual sum of £1,750,000 to place to the credit of the system.

Turning now to the by-products: seeing the gas companies, by the new arrangements, would subject three times the quantity of coal to the heat of their retorts during the period when the tar and ammoniacal liquors pass off most rapidly, I do not think I am wrong in estimating the yield at double its present amount. Taking this upon the tar and ammonia to yield 3s. 9d. per ton of coal, we find the total value of these by-products to be, at present, on the supposed consumption by the gas companies of 2,000,000 tons of coal per annum, £375,000. This being doubled under my scheme, an additional sum of £375,000 must be placed to its credit.

But the basis upon which we have hitherto been arguing is that the gas companies under the proposed scheme are getting their coal for nothing. We have been supposing that the community become the purchasers of 6,000,000 tons of coal and hand it to the gas companies. At present London only pays for its general consumption on 4,000,000 tons of coal and 1,000,000 of coke. Let us now suppose that the companies pay the same sum annually that they do at present for their coals; if so, they would pay upon 2,000,000 tons, or an annual amount of £1,600,000, if their coals cost 16s. per ton. From this falls to be deducted the money they at present draw from their sales of coke, which, when taken at 6s. per ton of coal carbonised under the existing system, still leaves a sum of £1,000,000, which they could afford to pay per annum for the use of the 6,000,000 tons of fuel as proposed in my scheme. We will now take the total payments of the community for their coal to be upon 6,000,000 tons, for which we will further suppose they pay at the rate of 16s. per ton first cost. This would amount to £4,800,000 per annum. From this has to be deducted the £1,000,000 contributed by the gas companies for the use of the fuel, also the £1,750,000 charged on the difference between the 16 and 24-candle gas already referred to, also the sum of £375,000 of additional income from the by-products. This would leave a net sum paid by the community for its fuel under my scheme of £1,675,000. Under the present system they have to pay, say 16s. per ton on 4,000,000 tons of coal, and say 12s. per ton on 1,000,000 tons of coke. This makes in all the sum of £3,800,000 per annum. Here then we have a balance in favour of my scheme of £2,125,000 annually. This may be taken as the yearly value of London smoke, which I propose to convert into useful products by the plant at present in use. I have only, in conclusion, to say one or two words about the efficiency of the scheme as regards the fuel. It lights easily, it gives off no smoke, it makes a cheerful fire, it gives out more heat than either coal or coke, it will be cheaper per heat-unit

than the coal at present in use, London would come a smokeless city, and all that would be deducted from the sum of £2,125,000 per annum would be confined to a few items, such as that of additional workmen employed in charging retorts, interest upon additional capital required to transit appliances, and the terms to be made with the gas companies for carrying out the scheme.

I have much pleasure in acknowledging that I have received from Mr. Wallace, the gasmaster at Woolwich Arsenal, and the valuable information obtained from Mr. Field's tabulated account of the London gas companies. So far as I am aware, my contributions to the *Builder* are the only writing on the subject of a proposal that has ever been made public. I say, in conclusion, that I have no pecuniary interest whatever in the scheme I propose.

#### DISCUSSION.

The Chairman said the lecturer had explained to consume smoke was a very difficult process, in fact, as far as he understood the problem, the real remedy was to prevent it from coming into existence. Smoke consisted principally of carbon, and required a large proportion of oxygen to be combined with it, and time could not be obtained in a furnace or in the flue. They knew that the most perfect powder manufactured and exploded in the most judicious way possible, was never wholly consumed, but portions of the grains—sometimes very large portions—were driven out unconsumed. That showed the difficulty of getting carbon into combination with a sufficient quantity of oxygen to produce full combustion. The reader of the paper spoke of Dr. Siemens having proposed a mode of extracting a species of crude gas from poorer classes of coal, but that it was not intended to be applicable for general purposes. That, however, was a mistake, as Dr. Siemens did intend to supply gas for all heating purposes to town communities, and a Bill was prepared and taken into Parliament at Birmingham for that purpose. It was to be sold and distributed as ordinary gas was, for purposes for which heat was required. He had spoken of 16-candle gas being 3s. 6d. per 1,000 cubic feet in London, but the companies in London were now charging 3s.: one on the Southern side charged 2s. 6d. the large Becton Company was charging 3s. 3d. It would, no doubt, shortly reduce it to 3s. There had been many complaints during the present frost, that the gas was affected in many ways. It reduced its volume by condensation to the extent of 5 per cent, it froze the taps and pipes serving it; the result being that at the London Company Board meeting that day there had about 2,000 complaints of want of proper supply during last week. The amount of coal said to be annually required for London was four million tons, which would impoverish more than 1,000 acres of three feet in depth. If, therefore, they could in any way diminish the enormous and disgraceful waste of fuel going on in this country, they would be doing a great national good. They were now using about 100 million tons of coal per annum, about 100 million being used in this country, and 10 millions being exported; and it was of the highest importance to go on exhausting our coal-fields at the present rate. Last evening he spent in company with an eminent chemist who had studied this question. Robert Angus-Smith, being chief inspector under the Alkali Act, and he had kindly written him a paper in which he would ask the Secretary to read. He then called on the meeting to discuss the paper; and asked them to keep as nearly as possible to the

following letters were read by the Secretary :—

Local Government Board, Whitehall,  
26th January, 1881.

DEAR MR. RAWLINSON,—I feel sure that you are an interesting paper from Mr. Scott-Moncrieff coming, but it will do no harm to send you some by no means in opposition, but with the belief the subject must be viewed in many ways. In my proceedings, under the Alkali Act for 1878, I have a plan, actually in use in Bességes, in the south of France, of making coke by distilling the coal, and saving all the products of distillation. I got the account, and have had it translated and published. I said that the coke is better than by air treatment, and some people deny this. Now, I show that if heated the 15 million tons of coal now used for this way, we should have a saving of 3½ million pounds direct, but the sulphate of ammonia, and as manure, would add eight million pounds of food to the produce of the land. If, as we treated all the coal in the same way, we add about 50 million pounds worth of bread and might begin to export. The calculation amount of food is made from results obtained by Messrs. Gilbert and Lawes, the greatest authorities, and is confirmed by letters from the value of the tar is separate from that. Part must be done. Is any work more important? of a revenue in amount fit for all the purposes of the nation. The sulphur itself would be of great stead of poisoning us in fogs, and hurting us as, as much of it would be commercially.

I am trying to stir up some people interested in making. I should like to see Mr. Scott-Moncrieff's plan tried where coke is not wanted, and we ought to try every good plan.—I am, sincerely,  
R. ANGUS SMITH.

Rawlinson, Esq., C.B.

description of the Bességes plan, referred to, is in a book. Alkali Act Report, presented to it, 1879.\*

London Gaslight Company, Works, Nine-elms, S.W.,  
25th January, 1881.

SIR,—We used 155,468 tons of coal last year, which yields ten gallons of tar; one ton yields, say, five gallons of ammoniacal liquor. Our tar last year worth £17,814; liquor about £14,000. I drew it two some days ago, after the charge had been made. Found it very difficult to draw, the softening up before the rake; the smoke, in drawing, a nuisance. The coke was very friable, was a quench, and would be little more than dust or twice handling. Moreover, to carbonise that extent only would require a much larger of fuel than is ordinarily used. I regret very much I cannot be at John-street to-night.—Yours  
ROBERT MORTON.

Rawlinson, Esq.

Mr. Morton wished to put two questions which to him of some importance, and which he had not scientific knowledge to answer for himself. He followed Mr. Moncrieff's right, the fuel which he used was practically identical with that which is now used universally in locomotive engines. The railway companies felt themselves at fault in polluting the atmosphere. He remembered, Mr. Morton, asking what they did with the gas, when he said it would not pay to collect it. Whether

that was correct or not of course he could not say, but he did know that almost every railway company in England and France had abandoned the use of coke, and he always understood that they did so because it did not pay to use it; and many of the coke ovens by the sides of railways had been pulled down. He should like to know the precise cause of this abolition, because this was an experiment on a very large scale, carried on for a long time. The other question was with regard to the quality of the gas made. It appeared to him that, not perhaps immediately, but in the not distant future, the greater part of the gas consumed in this country would be of a lower illuminating power, but giving more heat, than that now in use; and they must look to the electric light in some form or other replacing, to a great extent, the present mode of lighting. He did not believe this would affect the gas companies prejudicially, but he thought they would have to manufacture a different quality of gas, which would be used for cooking, heating, and as a motive power.

Mr. W. E. E. Coles (of the National Health Society) said there was about to be an exhibition of the various means by which the smoke of London might be prevented; and amongst those means gas would be particularly considered. He might say that the committee had had various recommendations from several gas companies, and on the committee they had a member of one of the London gas companies. The committee had also before it several useful inventions for improvements in the flues of houses; there were also inventions for reducing the smoke from bituminous coal by chemical means, and in particular there were several improved forms of grate for burning anthracite coal for domestic purposes. Since this movement had become popular, anthracite coal had been considerably introduced into London, and in many cases with success. As usual, in all important social matters, the Royal voice had been expressed in favour of the movement, and on the following day, at Kensington, Prince Leopold would preside at a meeting, one branch of whose business would be to consider the atmosphere of London in relation particularly to smoke.

Mr. Wolstencroft said that in 1873, there was an exhibition at Manchester of appliances for the economy of fuel, when his father, who was a clergyman, showed a fire-grate of his own devising. There had been a letter in the *Times* recommending that air should be brought in from outside to supply the fire, so as to prevent draughts in the room, and his father accordingly made a hole through the wall and admitted air from the outside. He found that inconvenient, as it blew the ashes into the room, but that difficulty was got over by fixing a piece of slate in such a manner as to confine the air entirely to the fire. This gave a very good fire indeed, and the combustion was so active, that for six months they used no other fuel than that obtained from a large heap of cinders and ashes at a neighbour's farm. Some hundreds of these grates were fitted in Manchester, but the public did not take them up, and the patent was now run out, so that anyone was at liberty to use it. Ordinary gas coke gave a better fire than coal with this grate, and anthracite coal would burn freely. Indeed, on one occasion, when there was no other coal at the exhibition at Peel-park, his father's was the only fire which would burn.

Mr. Hugh Clements thought the waste of fuel and the smoke of London had got to such a pitch that some means should be taken to lessen it. It seemed to him that the plan now brought forward would do much to abate the present nuisance, but any other means which would attain the same result should also be tried. There was no doubt if the gas companies took up this question, and dealt with it in the manner proposed, it would be a great success, as the quantity and quality of gas would be much increased, and also the by-products. With

Notes, 1873 and 1874. Fourteenth and Fifteenth Annual Report of the Society of Arts, during the years 1873, 1874 and 1875. Price 2s. 2d. "Manufacture of Bességes," p. 48.

regard to the consumption of coal in ordinary houses, there was no doubt it was about twice as much as it ought to be; houses were built with no regard to ventilation, which could only be obtained from badly fitting doors and windows, causing draughts. Great economy would be effected if a whole street were warmed by one large furnace, for all such operations were always better conducted on a large scale.

Mr. Engert thought too little care was generally bestowed on the way in which coals were stored; for he found, as the result of many experiments, that dry coal gave the gases out freely and caused but little smoke; when it lay for some time exposed to the air and absorbed moisture, it gave three or four times as much, and when it had been exposed to showers of rain it produced ten times as much smoke as dry coal. Unfortunately, most of the coal in London was kept in cellars exposed to damp and rain, and in one house where he lately went to see an experiment tried, it was so wet it would hardly burn. He had lately been talking a great deal to engineers and stokers on the matter, and they sometimes told him that the wind was very unfavourable to them, though they hardly seemed to understand why it was so. He thought every furnace ought to be so enclosed that the wind would not affect it. A great deal was said about the economy of the fuel for poor people, and he had no doubt that with a good cheap kitchener they might save a large quantity of the coal which now simply went up the chimney. He had an invention of his own, but he would not refer to it on the present occasion.

Mr. Webber said he would endeavour to bring the discussion back to the question at issue by asking Mr. Moncrieff one or two questions. He said that more heat was given out from this partially carbonised coal than from raw coal. If this was weight for weight, he (Mr. Webber) did not exactly see how coal from which a certain weight of combustible had been drawn could possibly give out as much heat as if all that combustible remained in it. Mr. Morton, in his letter, touched a very serious point when he said that he had tried drawing a charge of coal,  $1\frac{1}{2}$  or 2 hours after it was put in, and he found great difficulty. He had had some experience in the matter, and he could bear out Mr. Morton's statement in that respect. It was always possible to see in a gas works when the coal was properly carbonised, without going near the retort; for if it came out too soon it made a most tremendous smoke. Unless Mr. Morton's statement could be shown to be wrong, if only one third of the gas was produced, three times the weight of coal could not very well be burned off, and if that were not so, the existing plant could not do the work. If it was possible to partially carbonise three times the amount of coal in the same time, the case was very different, but from Mr. Morton's statement, supplemented by the experience of every gas manager, he did not think it was altogether clear. He would call attention to the report of Dr. Ballard, who carried out a long inspection of various manufacturing processes where noxious vapours and smoke were given off, and he partially drew attention to the fact that, when coal was not properly burned off in gas works, a very great nuisance was occasioned in the neighbourhood. The present system might be all wrong, but if it were, the gas companies would not be at all backward in taking advantage of any better system that would give them one or two per cent. more dividend.

Mr. Lawson desired to express the great pleasure he had felt in listening to this very able and interesting paper. To him the idea was theoretically perfect, and if it could be carried into effect, he had not the slightest hesitation in saying that London would be smokeless to-morrow. The volatile products were of course now being wasted and sent up the chimneys, and if they

could be first utilised, as Mr. Moncrieff had shown destructive distillation in retorts, there was no doubt they would all be sources of revenue to the community and it would clear the air of large towns of smoke. The last speaker had referred to the statement with regard to more heat being given out by this fuel than that which arose from the large amount of heat now used in volatilising the products of the raw coal. That disappeared, and would reappear in the fuel which was to be supplied. He had been much struck with the figures given, showing the great economy which had been effected. Assuming six million tons of coals to be consumed annually in London, and taking them at an average price of £1 per ton, that was £6,000,000 which it was reckoned there would be a saving of £2,000,000. But he did not think account had been taken of the extra labour which would be required to work three times the present amount of coal in the retorts. He had not much hope of the scheme being adopted in London just yet, but if Mr. Moncrieff went down to Birmingham and read his paper, and showed that a saving of £100,000 could be effected, he had little doubt it would soon be taken up.

Mr. Lawry Whittle said that, as a member of a committee of which Mr. Coles had spoken, he had many discussions with various people as to the best method of preventing smoke. There were several methods proposed, especially the introduction of new appliances and of new fuel, including anthracite and coke; and he was very important that these things should be put before the public in a clear and systematic way, as he had done that evening. He had found anthracite useful, but had not yet heard anything so important as this proposed on the question of coke, and he looked to the proposal as one of the most important means of meeting the problem. He was happy to think that the people were beginning to recognise the evil as one within the scope of their own energies to deal with. They had to deal in London with a public of several millions; they could not, in his opinion, deal with them by legislation, but must adopt the remedies, and by degrees induce them to adopt them. Mechanical appliances might attract some people, different fuels would attract others, and among these, partially coked coal had always presented itself to him as one of the most promising.

The Chairman, in concluding the discussion, said he presumed Mr. Moncrieff would take his coal for oil purposes as new as possible. This was an important point, because gas coal was very volatile, and if it was on the surface for any length of time, it very rapidly depreciated, from 5 up to as much as 25 per cent. With regard to the value of the waste products, if all the coal now burned in open fireplaces were so treated as to remove those tarry and residual products, which now went up the chimneys and only did injury, available as they were in gas works, the result would be astonishing. Mr. Morton, in his letter read by the Secretary, stated that, at the London Gas Works, about 155,000 tons of coal were carbonised per annum, and the real profits in tar and ammoniacal liquor were £31,814. They multiplied that by 13, which would bring the saving to nearly 2,000,000 tons, that would represent a saving of £113,582, which was now sent into the London atmosphere to do nothing but mischief. It was quite true that Mr. Moncrieff did not propose to exhaust the coal to the same extent as the gas company did now, and that that would reduce the volume and relative value of the residual products he was not prepared to say. With respect to the remarks of Mr. Morton as to the difficulty of drawing the retorts, no doubt there would be that difficulty with the retorts, as they were arranged at present because he knew Mr. Morton intimately, and knew him to be an extremely careful and intelligent man, like the reader of the paper, he came north of Tweed. Whether the process would be the same for partial distillation, whether the apparatus would

is, whether the retorts would be the same, not prepared to say; but it was quite clear that it could be made by different processes and in different manners. It was true, as had been said, that railway companies did once use coke entirely in their locomotives; but he did not know that they had abandoned it so much on account of the cost, though that had certainly come into the consideration; but the first engines were small, and the firebricks were also small, so that they could not use coal to produce steam. They had now enlarged their firebricks and arranged their apparatus so perfectly that they could use coke. But they did not formerly use the coke. Mr. Moncrieff contemplated, but used a coke retort, from which all the residual products went into the atmosphere, smoke and all, and nothing was left but the bare carbon; which, according to the value from the gas works, really had the least value. Mr. Moncrieff intended to preserve all the residuals of coke as well, he did what the coke makers for railway companies never did. Again, though the old retorts were abandoned, the making of coke was not done to a large extent, because it enabled them to turn their small coal, which had little value for a product which had great value for the purposes of smelting, puddling furnaces, and for steel making, whilst the heat which came from the ovens was wasted, but was utilised for steam purposes. Mr. Moncrieff, in reply, said the most important, perhaps, raised, was that mentioned by Mr. Morton, who had evidently made a practical experiment. This weighed very much with him; and he had no hesitation in saying that if his plan were adopted, great skill, competitive skill, would have to be brought to bear on the production of the best form of fuel. One of the places he had with him, from which 6,000 feet of iron had been taken, was, like that described by Mr. Morton, exceedingly friable; but another sample of coke as well, he did what the coke makers for railway companies never did. In an experiment such as that of a spoke of, he believed an exceedingly spongy coke of coal ensued, which, no doubt, would have been of use. The tar began to exude; and at that stage of distillation the coal would hardly be left at all. It might be that special means would have to be taken by the gas companies; the fuel was compressed; or it might be treated in various ways, if the object to be attained was such as that to be the opinion of the meeting that it was. He had no doubt that the fuel might be made perfectly available for carriage and for use. It had been with difficulty withdrawn from the retort with the others it was not so. The atomic or condition of the material was exceedingly friable and some skill would no doubt be required to produce the best effect. The Chairman had replied fully to the question put by Mr. Morton as to early locomotives. As to the electric retorts, there were various views with regard to it, and he could not say whether it would come into use next year, the year after, or in two or three years. His were really a reasonable scheme for dealing with the nuisance which was affecting the health of the community, and it could be carried out at no great cost without much trouble, even looking at it as a remedy, it would be better to adopt it than to do nothing for a light about which, to say the least, was a great deal of discussion. Mr. Webber said the heat in this fuel could be greater than in the best at 20 per cent., he had spoken of it as information, but Mr. Lowson had pointed out the explanation of the present anomaly. If you use a quantity of coal and a quantity of water, to turn it into steam required an enormous quantity of heat, in condition into which the water was converted, the thermal equivalent of the change. The same with the coal; it required a consider-

able amount of heat to convert it into gas, and there was a thermal equivalent in the one case the same as in the other. By treating it in an open fireplace, the appearance was very cheerful, but an immense deal of heat was absorbed in the process. It was for the same reason that the wick of a lamp was not consumed. It was very near the flame, which was at a very high temperature, and yet it was not consumed—except very slowly—because between the flame and the wick the process was going on of converting the oil into the gaseous constituents, which represented the thermal equivalent, and kept the wick practically cool. A difficulty had also been suggested with regard to the smoke, but that was really a matter of detail, which would be very easily dealt with. A large funnel could be easily arranged over the mouth of the retort, with an exhaust fan which would carry off the smoke, and the men would be better off than at present, the smoke, of course, being taken into the furnace. He had not, as Mr. Lowson supposed, overlooked the question of additional labour, though he had not gone into it in detail, as it was difficult to estimate exactly. He believed it would approximately amount to trebling the number of men employed, in which case perhaps £100,000 might be expended.

The Chairman then proposed a vote of thanks to Mr. Scott-Moncrieff, which was carried unanimously.

## MEETINGS OF THE SOCIETY.

### ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

FEBRUARY 2.—“Trade Prospects.” By STEPHEN BOURNE.

FEBRUARY 9.—“The Present Condition of the Art of Wood-carving in England.” By J. HUNGERFORD POLLEN. Sir PHILIP CUNLIFFE-OWEN, C.B., K.C.M.G., C.I.E., will preside.

FEBRUARY 16.—“The Participation of Labour in the Profits of Enterprise.” By SEDLEY TAYLOR, M.A., late Fellow of Trinity College, Cambridge.

FEBRUARY 23.—

MARCH 2.—“Flashing Signals for Lighthouses.” By Sir WILLIAM THOMSON, LL.D., F.R.S.

MARCH 9.—“Improvements in the Treatment of Esparto for the Manufacture of Paper.” By WILLIAM ABNOT, F.C.S.

MARCH 16.—“The Manufacture of Aerated Waters.” By T. P. BRUCE WARREN.

MARCH 23.—“The Increasing Number of Deaths from Explosions, with an Examination of the Causes.” By CORNELIUS WALFORD.

MARCH 30.—“Recent Advances in Electric Lighting.” By W. H. FREECE, Pres. Soc. Tel. Eng.

Dates not yet fixed:—

“Buying and Selling; its Nature and its Tools.” By Prof. BONAMY PRICE. On this evening Lord ALFRED S. CHURCHILL will preside.

“The Discrimination and Artistic Use of Precious Stones.” By Prof. A. H. CHURCH, F.C.S.

“The Compound Air Engine.” By Col. F. BEAUMONT, R.E.

### FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

FEBRUARY 1.—“The Industrial Products of South Africa.” By the Right Honourable Sir HENRY BARTLE FREERE, Bart., G.C.B., G.C.S.I., D.C.L., LL.D. Sir RICHARD TEMPLE, Bart., G.C.S.I., C.I.E., D.C.L., will preside.

FEBRUARY 22.—“The Languages of South Africa.” By ROBERT N. CUST.

MARCH 15.—"The Loo Choo Islands." By Consul JOHN A. GUBBINS.

APRIL 5.—"Trade Relations between Great Britain and her Dependencies." By WILLIAM WESTGARTH.

#### APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

FEBRUARY 24.—"Deep Sea Investigation, and the Apparatus used in it." By J. G. BUCHANAN, F.R.S.E., F.C.S. Captain Sir GEORGE S. NARES, R.N., K.C.B., F.R.S., will preside.

MARCH 24.—"The Future Development of Electrical Appliances." By Prof. JOHN PERRY.

The meeting previously announced for April 7 will be held on May 12.

#### INDIAN SECTION.

Friday evenings, at eight o'clock:—

FEBRUARY 11.—"The Gold Fields of India." By HYDE CLARKE. Sir WILLIAM ROBINSON, K.C.S.I., will preside.

MARCH 4.—"The Results of British Rule in India." By J. M. MACLEAN.

MARCH 25.—"The Tenure and Cultivation of Land in India." By Sir GEORGE CAMPBELL, K.C.S.I., M.P.

MAY 13.—"Burmah." By General Sir ARTHUR PHAYRE, G.C.M.G., K.C.S.I., C.B.

#### CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Second Course will be on "Watchmaking," by EDWARD RIGG, M.A. Three Lectures.

#### Syllabus of the Course.

##### LECTURE I.—FEBRUARY 7.

Introduction—Units of Time—Historical Sketch—Description of usual forms of watch—Escapements—Conditions of accurate timekeeping, and arrangements necessary for their maintenance in the higher class of watch.

##### LECTURE II.—FEBRUARY 14.

The ordinary watch—Degree of accuracy required in it—Systems of manufacture in this country and abroad—Description of specimens illustrative of the various stages of construction—Comparison of the several systems.

##### LECTURE III.—FEBRUARY 21.

Necessity of efforts to promote the art in this country—Need of education, theoretical and practical, in horology—Literature—Great want of uniformity in gauges, screws, &c.—Exhibition of ordinary and complicated watches, and of watchmakers' tools—Conclusion.

The Lectures will be illustrated by Specimens, Models, and Diagrams. The different movements, &c., will be shown enlarged on the screen by means of the Aphengiscope and the Electric Light.

The Third Course will be on "The Scientific Principles involved in Electric Lighting," by Prof. W. G. ADAMS, F.R.S. Four Lectures.

March 7, 14, 21, 28.

The Fourth Course will be on "The Art of Lace-making," by ALAN S. COLE. Three Lectures.

April 25; May 2, 9.

The Fifth Course will be on "Colour Blindness and its Influence upon Various Industries," by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

May 16, 23, 30.

#### ADMISSION TO MEETINGS.

Members have the right of attending Society's meetings and lectures. Every can admit two friends to the Ordinary and Meetings, and one friend to the Cantor Books of tickets for the purpose have be to the Members, but admission can also be on the personal introduction of a Membe

#### MEETINGS FOR THE ENSUING WEEK

MONDAY, JAN. 31ST...Royal Geographical, University Burlington-gardens, W., 8½ p.m. Mr. E. Delb "A Journey to Semiretchia and Kuldja in British Architects, 9, Conduit-street, W., 1 C. Purdon Clarke, "Persian Architecture struction."

Institute of Actuaries, The Quadrangle, Kin W.C., 7 p.m. Mr. T. B. Sprague, "The Use and Use of a Series of Select Mortality 1 used in connection with the Institute. Hm. Parts II. and III.

Medical, 11, Chandos-street, W., 8½ p.m. London Institution, Finsbury-circus, E.C., 2 Mark Pattison, "The Thing that might be

TUESDAY, FEB. 1ST...SOCIETY OF ARTS, John-str W.C., 8 p.m. (Foreign and Colonial Se Right Hon. Sir Henry Bartle Frere, Bart., trial Products of South Africa."

Royal Institution, Albemarle-street, W., 3 E. A. Schäfer, "The Blood." (Lecture III Civil Engineers, 25, Great George-street, V S.W., 8 p.m. 1. Discussion upon "Deep Coal in South Wales." 2. Mr. Charles Colmouth Dockyard Extension Works."

Pathological, 53, Berners-street, Oxford-street Biblical Archaeology, 9, Conduit-street, W., 8 Zoological, 11, Hanover-square, W., 8½ p.m.

WEDNESDAY, FEB. 2ND...SOCIETY OF ARTS, Adelphi, W.C., 8 p.m. Mr. Stephen Bou Prospects."

Geological, Burlington-house, W., 8 p.m. M. Duncan, "The Coralliferous Series of Connection with the last Upheaval of the 1 2. Mr. P. Herbert Carpenter, "Two New C the Upper Chalk of Southern Sweden."

Entomological, 11, Chandos-street, W., 7 p.m. Pharmaceutical, 17, Bloomsbury-square, W Prof. Redwood, "The Weights, Balances, a Employed in Pharmacy, the Errors which a Occur in Using them, and Means by which Required in the Weighing and Measuring may be Promoted."

Obstetrical, 53, Berners-street, Oxford-street, Annual Meeting.

THURSDAY, FEB. 3RD...Royal, Burlington-house, W., Antiquaries, Burlington-house, W., 8½ p.m. Linnean, Burlington-house, W., 8 p.m. 1. Bentham, "Notes on Cyperaceae." 2. Day, "Observations on some British Fish Wm. Biddie, "Remarks on the Coffee-lee India." 4. Dr. M. C. Cooke, "Coffee Disease America."

Chemical, Burlington-house, W., 8 p.m. 1. and Hake, "The Estimation of Organic Ca 2. Mr. M. W. Williams, "The Action of Zinc Couple upon Nitrates."

London Institution, Finsbury-circus, E.C., R. H. Scott, "Three Years of Daily W casting."

Royal Institution, Albemarle-street, W., 3 Francis Hueffer, "The Troubadours." (I Civil and Mechanical Engineers, 7, Westminster S.W., 7 p.m. Mr. W. C. Street, "Draini banking with regard to River Outfalls."

Archaeological Institution, 16, New Burli 4 p.m.

FRIDAY, FEB. 4TH...Royal United Service Institute yard, 8 p.m. Colonel T. Lynden Bell, "T Defensive, by Infantry in Extended Order." Royal Institution, Albemarle-street, W., 1 Andrew Wilson, "The Origin of Colonial C Geologists' Association, University College, Philological, University College, W.C., 8 p.m.

SATURDAY, FEB. 5TH...Royal Institution, Albemark 3 p.m. Prof. Sidney Colvin, "The (Lecture III.)

## L OF THE SOCIETY OF ARTS.

No. 1,472. Vol. XXIX.

IDAY, FEBRUARY 4, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W. O.*

## NOTICES.

## EXHIBITION OF 1851.

The Council have had under consideration the question of erecting a memorial on the site of the Exhibition of 1851, and have decided that it is very desirable that such a memorial should be erected. The following letter was sent by the Secretary of the Commissioners of Public Works (Mr. G. S. Lefevre) would receive a reply from the Council on the subject:—

23rd December, 1880.

The Council of the Society of Arts have the pleasure to request you to inform the Commissioners of Public Works that they consider it desirable to record, by a monolith, the site of the Great Exhibition of the Works of Industry of all Nations, held in 1851 in Hyde-park. They propose to raise the necessary sum by a public subscription, a task in which they expect no great difficulties. It is necessary to obtain the consent of the several official authorities, and when that has been secured, to obtain the sanction of Her Majesty the Queen.

The Council therefore apply for the permission of the Commissioners of Public Works, to place in Hyde-park, near the spot where the Queen opened the Exhibition on the 1st of May, 1851, a Monolith of granite or other durable stone, with suitable inscriptions. The design, treatment, and material of such Monolith would, of course, be subject to the approval of the Commissioners.

The Council have deputed Mr. F. J. Bramwell, F.R.S., F.P.Inst.C.E., Chairman of the Council; Mr. F. J. Cole, K.C.B., a Vice-President; and Mr. W. Roberts, M.A., one of the Treasurers on the subject, to confer with the Commissioners on the subject, and, in view of carrying the design into effect, to seek permission to use the ground. The Society, in respect of Arts, Manufactures, Commerce, and general civilisation, has derived the greatest benefits from the Great Exhibition of 1851, which has already been the progenitor of International Exhibitions in all parts of the world; and there seems every probability of the continuance of them.

The Society will appeal with confidence to the public for the funds necessary to make a memorial of the object, and likely to last for many years. Every body must feel a pride that this

country was the originator of the first International Exhibitions, and especially the hundreds of thousands of individuals who have derived direct personal benefit from them.

I have, &amp;c.,

H. T. WOOD, *Secretary.*

A. B. Mitford, Esq.

In accordance with the appointment made by Mr. Mitford, on Monday last, the 31st January, a deputation, consisting of the Chairman, Mr. F. J. Bramwell, F.R.S., Sir Henry Cole, K.C.B., Dr. B. W. Richardson, F.R.S., Mr. Owen Roberts, M.A., and the Secretary, had an interview with the Right Hon. G. J. Shaw-Lefevre, M.P., the First Commissioner of Works, and Mr. A. B. Mitford, the Secretary of the Board. The deputation discussed the question with the First Commissioner, who stated that if he could be satisfied an adequate and suitable monument could be provided, he would be prepared to recommend that permission should be granted for its erection on the spot in Hyde-park, where the Great Exhibition building stood.

The Council will endeavour to raise subscriptions for the purpose, and will submit a more detailed scheme to the First Commissioner of Works, as soon as they are able to come to a decision upon the precise character it is desirable the monument should take.

## NATIONAL TRAINING SCHOOL FOR MUSIC.

The Council, at their last meeting, resolved to make a grant of £160 to the National Training School for Music, in answer to the application from the School for a renewal of the four Scholarships founded by the Society.

## LABEL FOR PLANTS.

The Council are prepared to award a Society's Silver Medal, together with a prize of £5, which has been placed at their disposal for the purpose by Mr. G. F. Wilson, F.R.S., for the best label for plants.

The object of the offer is to obtain a label which may be cheap and durable, and may show legibly whatever is written or printed thereon; the label must be suitable for plants in open border. These considerations will principally govern the award.

Specimen labels, bearing a number or motto, and accompanied by a sealed envelope containing the name of the sender, must be sent in to the Secretary not later than the 1st May, 1881.

The Council reserve to themselves the right of withholding the Medal and Prize offered, if, in the opinion of the judges, none of the specimens sent in are deserving.

## PROCEEDINGS OF THE SOCIETY.

### APPLIED CHEMISTRY AND PHYSICS SECTION.

Friday, January 27th, 1881; J. C. STEVENSON, M.P., in the chair.

The paper read was on—

#### A NEW MECHANICAL FURNACE, AND A CONTINUOUS SYSTEM OF MANUFACTURING SULPHATE OF SODA.

By James Mactear, F.C.S., F.I.C.

The manufacture of sulphate of soda—or “salt-cake,” as it is termed in the alkali trade—is, as a branch of chemical industry, second only to that of sulphuric acid in importance. It is the first stage, so to speak, in the production of alkali, or “soda ash,” and bleaching powder, articles which are essential in most of the industries of our country.

The process is a very simple one. Common salt is mixed with sulphuric acid, and the mixture is exposed to heat in a furnace, the resulting products being sulphate of soda and hydrochloric acid gas. In practice, however, the process has various drawbacks, the escapes of gas, more or less in amount, are very annoying to the workmen, and the labour is severe.

During the early days of the alkali manufacture, the operation of “decomposing” the salt was conducted in a small furnace of the reverberatory class, and all the acid vapours were allowed to escape into the air through the chimney. As the trade or manufacture grew in importance, and the quantity of salt decomposed rapidly increased, the damage to crops and vegetation generally, and the great nuisance occasioned by the evolution of the acid gases, caused such complaint, that measures of some kind or other were adopted by all manufacturers to lessen the amount of acid gas escaping. Many ingenious plans were tried with more or less success. That of Mr. Gossage, however, rapidly proved its great superiority over all the others, and it is now adopted by almost all manufacturers of alkali.

While the gaseous products were thus being dealt with, constant endeavours were also being made to improve the construction of the furnaces, but not with the same complete success as in the condensation of the acid gases. These, even so early as 1839, had become such a source of nuisance that we find a patent actually taken out by a Mr. Ford, with a view of carrying on the operations connected with the decomposition of salt “on board a flotilla at sea, at such a distance from land so that the gases may not reach shore.”

It will be interesting to follow the gradual changes which have been made in the form of, and manner of working, the furnaces from time to time. Originally the furnace employed in Great Britain was a simple reverberatory furnace, and in it the salt and acid were mixed on the brick hearth, and the acid fumes allowed to escape with the products of combustion into the chimney. As a considerable draught could be used with this furnace, the work-

men say that they were rarely incommoded by acid gases.

After the invention of the bleaching-process, by Charles Tennant, in 1791 chlorine was produced from a mixture of manganese, and sulphuric acid, until about the year 1823, when a system of decomposing in furnaces, and condensing the hydrochloric in water, came into use. In the first instance iron cylinders were used, and the condenser made of earthenware pipes, and packed in cases with flints or pebbles. About this time furnaces with two beds or divisions were introduced, these having been previously used in France already, in 1816, the firm of Chaptal and Co. were condensing their hydrochloric acid utilising it in the manufacture of gelatinous bones. Amongst the old papers of my firm is an interesting series of letters from the named gentlemen, in which, under date of 1816, they say they were then working 41,000 lb. per day of crude soda (black ash), of 20 per cent. alkali, and were using salt produced at Marseilles by the evaporation of the sea-water, the consumption of sulphuric acid being stated at 100 per cent. on 100 salt.

In the gradual alteration of the form of the simple reverberatory with which the first change was a mere alteration in form and dished out into a basin-like form. This furnace was used for a number of years under the name of the “Dandy furnaces.”

The following extract from an old paper on the manufacture of salt-cake, is interesting:—

“The muriatic acid is the alkali manufacture bear, proving an intolerable nuisance to the neighbourhood, if allowed to escape into the air, an exceedingly troublesome to condense perfectly. salt-cake is made in such furnaces (the Dandy) evolved muriatic acid is so intermingled with smoke, that its complete separation is nearly quite, impossible. The only method is by passing mixed gases over an extensive surface of cold but this, if carried on sufficiently to condense the acid, would, by cooling the air, create draught; in practice, therefore, it can only succeed. The greater part of the acid may be drawn, and the nuisance thus materially lessened, some must still escape, and prove, to the neighbours' annoyance, that the remedy is ineffective.”

The next stage in the development of the salt-cake furnace, was its construction with two instead of only one, as previously used. The first or decomposing bed, being at one time with a leaden pan, lined with brickwork, the roaster bed was bottomed with brick. In a short time the leaden pan was replaced by one made of cast iron, built up in place and likewise lined with bricks, and this furnace was used somewhat extensively for many years. On May 8th, 1837, however, Bell patented a furnace which introduced the muffle principle; the furnace, or oven, as he had only one bed, was constructed with a pan, protected both outside and inside by work, and arched over with a double that the fire gases, after first passing through a series of flues underneath the bed or hearth over the top between the two arches, so that bottom and top heat were secured.

ea was apparently quite a new one, and it dily improved upon by J. C. Gamble, in arch 14th), who proposed the use of three , ovens, or retorts, one to be used as the sing or mixing portion, and each of the lternately were to receive, and finish the rom the first division when it had been up. Lee almost immediately afterwards id a form of open furnace, in which a cast-or pan was employed, spoon-like in form. e again improved upon this form of pan, ong a furnace with two roasting beds, and shallow pan heated by the waste heat from ers passing over it, was in use.

this point invention seems to have been into two channels, first, towards the pro- of the largest amount of strong muriatic ding to the development of the close or rnace, and second, towards the cheapest f producing salt-cake—leading to the nent of the open roaster, or ordinary Tyne

lose roaster furnaces are those now chiefly the Western district and in Scotland, ie open furnaces are more generally used in e and Eastern district generally.

nuffle furnace now in general use varies its dimensions, construction, and general a few of these varieties are shown in the as now on the wall, but within the past two very great improvements have been ced into the construction of these furnaces ars. Muspratt, Gamble, and Deacon, who lained at so arranging the combustion of las to obtain in the flues a pressure rather draught.

amble's most ingenious arrangement, gaseous employed, the air for its combustion being y passing through a nest of iron pipes in the flue, so that the waste heat is to some : utilised, while a considerable amount of pressure is obtained in the flues of the

on, on the other hand, obtains the same with ordinary fuel, by sinking the fire-grate pth below the floor line, and taking advan- of the power of the ascending column of fuel

This furnace has had considerable success, as reduced very much indeed the leakage h the arch of the furnace, a fault all muffle es are very liable to have.

each for the close or muffle furnaces. The class, the open roaster or furnace, has as so much improved in its old form. t approved form is that with an iron pan : "roaster," the pan being heated by a fire, and in many cases the roaster being h coke, so as to avoid the choking up of lensers with soot.

these various forms of furnace to which I led your attention, the operations are con- means of manual labour, which is severe a itself, but which is rendered much more amount of acid vapours which the work- to bear with, more especially when dis- the furnaces, and which render it much cult to replace this class of workmen, than almost any other department of an alkali

chanical arrangements instead of manual labour was one that very early presented itself to alkali manufacturers, and I have here a drawing of one of the first attempts to carry out this idea, which was tried in or before 1842.

The arrangement of machinery for operating chemical furnaces patented by Pattinson in 1848 was the first real step in the direction of reducing manual labour, and, although it was not so successful as was anticipated, it has helped to show the way to more perfect appliances.

It is true that towards the end of his specifica- tion he points out, as regards the usual form of de- composing furnace with pot and roaster, that his apparatus was only suitable for the roaster; but at the beginning of his specification he distinctly points out the application to a decomposing or salt-cake furnace with a single bed, where the salt and acid "are heated, with constant stirring, until the muriatic acid is driven off, and it has become sulphate of soda," and his claim is also clear upon this point. Little more seems to have been done until Jones and Walsh took out their patent in 1875 for a form of furnace consisting of an iron pan of a circular form, which formed the bed of the furnace, upon which the salt and acid were mixed and stirred by scrapers and ploughs, operated, as in Pattinson's furnace, by a central shaft.

The special feature of the patent of Jones and Walsh was a return to the old class of furnace with a single bed, and the doing away with a large amount of the manual labour. It was hoped that this furnace would have been a great success, and a considerable number were erected; but most of these have been, more or less, failures, chiefly owing to the great wear and tear of the machinery, and consequent heavy cost for repairs. Whenever these furnaces have been worked at anything like their alleged capacity, the breakages have been a constant source of trouble, and only when they have been worked lightly have they been at all successful. In some few cases they have been steadily worked for considerable periods without any serious breakdowns, but in these cases there has been great care taken never to overwork them, thus keeping down the heat, and saving tear and wear.

The mechanical difficulties have, it is believed, been, to a considerable extent, overcome in the more recent furnace, patented by Jones and Walsh, in March, 1880, which is constructed almost entirely on the principle of the Mactear calcining furnace, patented in May, 1876, and which is now well known and extensively adopted. But the greatest objection of all to the system adopted by Jones and Walsh—and which holds good equally with the new form of their furnace—is, that the salt and acid being all added within a comparatively small period of time, there is a great evolution of muriatic acid gas at the begin- ning of the operation, and a rapidly decreasing amount as the process continues. The following figures show the above fact very clearly:—

#### *Furnace charged with KCl.*

Commenced to charge at 9.30 a.m.

The temperature of the gases entering the condenser, after passing through 300 feet of piping, ranged between 174° Fahr. at 10.15 a.m. to 110° Fahr. at 7.15 p.m.

Great care is necessary in working the condensers when all the acid is required to be high strength, say 30° to 31° Twaddell. The amount of water running into the condenser having to be altered many times during the progress of the charge, a wash-tower of some sort is needed, before allowing the gases to pass to the chimney.

One feature is well worth noting; there is a very considerable reduction in the amount of vitriol required for the decomposition. This, of course, applies to a greater or less extent to all mechanical furnaces, as the mixture of the salt and acid is not only more rapid, but more complete than it can ever be in hand-worked furnaces. The amount of this saving is stated by various manufacturers who have tried these furnaces of Jones and Walsh to be from 4 per cent. to 5 per cent. on the vitriol used. Various other patents have been taken out for mechanical arrangements, but none of these call for much attention, except that form of furnace or apparatus invented by Cammack and Walker, which, introducing as it does a new phase of the question, is well worth careful study. To these gentlemen belongs the credit of first proposing and carrying out the continuous decomposition of salt in a muffle furnace, although the mechanical difficulties connected with their apparatus have as yet proved too much for their complete success.

The apparatus consists of a cast-iron cylinder, about 20 ft. in length, heated externally by a series of carefully-arranged flues, and made to revolve on bearing-wheels. The salt and acid are fed in at one end continuously, and forced onwards by a screw and scraper arrangement, mounted on a shaft which passes through the cylinder, the passage of the materials through the cylinder being also assisted by its being laid with a slight incline (like Oxland's calciner for ores); the finished sulphate of soda is delivered at the lower end of the machine, and, the hydrochloric acid gas being not at all diluted by air or fuel gases, is very easily condensed.

Great hopes of this furnace being an entire success were entertained; but, after a considerable expenditure of money and a lengthened trial, it has been given up, the mechanical difficulties having proved too great so far.

Therefore, it will be seen no thoroughly satisfactory furnace which will produce sulphate of soda mechanically had as yet been introduced, but the question was one that called urgently for solution. On careful consideration of all the various systems proposed from time to time, and believing that a continuous method, such as is indicated in the animal charcoal revivifying process of Norman and others, and applied to salt-cake by Cummack

and Walker, was the proper direction in work, I abandoned a series of attempts had made to produce a mechanical muffle and determined to work out the problem tinuous salt-cake furnace on the open principle.

The conditions with which a mechanical cake furnace must comply in order that successful, are much more stringent than case of any of the other furnace operations alkali work.

In designing a furnace the following points (amongst others) carefully considered provided for, otherwise there is great likelihood of failure and expense:—

1. Simplicity and strength of the arrangement.
2. Convenient access to all wearing parts for facilitate repairs.
3. Economy in working.
4. Freedom from escape of acid vapour.
5. Simple delivery of finished sulphate without escape of acid vapours.
6. Simplicity of arrangements for removal of acid and salt.

The experience gained from several years of the "Mactear" carbonating and furnace, which has been so completely in dealing with the question of calcining soda alkali by mechanical means, pointed at the suitability of its general design as a basis of construction of a salt-cake furnace.

It required, however, a long period of many abortive designs and plans, ere the details were worked out, so as to give grounds for belief that all the necessary had been attended to, and provided for, and was good ground for belief that the furnace was likely to be successful.

The furnace, patented in November, shown in the diagrams, has been the result of attempt to solve the problem of a mechanical cake furnace, and it has been successful. The general construction is very much the same as the "Mactear" carbonating furnace, being a pan resting on radiating arms, which are on pivot wheels, on which the furnace revolves on wheels running on a race or rail, and the furnace being kept from working out of truth by the pivot or bearing; the furnace is covered by an arch, carried on a curb piece, supported by pillars, and the emission of acid gas is regulated by a lute, which surrounds the furnace.

The bed, however, of the furnace, differs from the "Mactear carbonator," in that, instead of a central opening for discharging the acid, there is a small iron pan or pot, which first receives the acid and salt as they are fed into the furnace. The flow of acid is constant, and is regulated by a slide and equilibrium valve construction. The supply of salt is introduced into the furnace by a screw, supplied from a hopper kept filled with salt, the screw being driven by a ratchet wheel, driven by a connecting rod and a lever and pall, capable of accurate adjustment as to length of stroke, gears into the screw so that the amount of feed given to the furnace can be governed with the greatest ease.

The salt and acid being continually fed into the centre pot, this becomes full, and the ex-

dge into the bed. This may be either in concentric rings or, as in my later without division. As the feed continues, als gradually work outwards, until the e of the furnace is reached, when the now completely finished, falls down series of ducts into an annular channel, losed by a cover bolted to the furnace ing with it, and which works in lutes so nt the escape of gas; the sulphate, as it his channel, is caught by scrapers, and id to a large box or hopper, from which out into waggons or barrows. terials are mixed and turned over by oughs, or scrapers, placed, as in the Mac- nator, between the two flues, through acid vapours and products of combust- away to the condensers, where they are to a great extent from the heat.

l of the furnace is lined with fire-brick, tar, and set in a special cement, which ber- der than ever when subjected to the the heat and sulphate, the whole bed nto one compact mass, which resists very the action of the materials put into the

ating of the furnace may be carried out onvenient, either coke, coal, or gaseous g used; care must be taken, however, ough combustion is attained, so as to oot being passed on into the condensers, t only wasteful in fuel, but apt to stop ensers up.

eat advantage of a continuous plan of de- ig salt is to be found in connection with ensation. The flow of water need not be or days, as once set for a given quantity nd strength of acid there is little likelihood quiring to be altered until some change ce in the quantities being worked.

is no difficulty in getting all the hydrochloric lensed at a strength of 28° to 30° Tw., with- wash tower, and with an escape in the chim- ough less than the Alkali Act allows. There is weak acid produced, a great point gained furnace of the open principle, and one laces it at once on a level with the close or rnaces, in which this production of strong e is the great advantage. The amount of ng plant also is very much less with the ace, in fact, not so much as one half what ound necessary with the close or muffle now in use.

alt-cake, as it is withdrawn, is almost free from smell or acid vapour, and there ole of gas to be seen about the furnace ile working. The appearance alone of the, has been found almost sufficient to ie workmen to regulate with great nicety f sulphuric acid. The results of the f average samples made on each shift for a s Table next column) will show this.

vented the use of ground rock-salt in the ordinary furnaces altogether disappear with this furnace, as it works rock-salt perfectly, and with it turns out a greater weight of finished sulphate per shift, of a quality which need not contain, at any time, more than  $\frac{1}{2}$  per cent. of undecomposed salt.

The quantity of work done depends, to a great extent, upon the draught. In the case of the furnace now at work at St. Rollox (which is connected to a small chimney with little heat in it, so that the draught is exceedingly bad), the work done is about 135 tons per week of seven days—nearly 10 tons per shift; this with common salt, with about 7 per cent. moisture. With a better draught, one ton per hour will be easily finished from common salt with this furnace, which is of 21 ft. outside diameter. Deducting the area of the small pan, and of the outer ring, say 12 in. broad, there remains as a calcining bed about 231 square feet, which, finishing at the rate of one ton per hour, would give about 10 lbs. per hour as the amount calcined per square foot.

The quality of the salt-cake is completely under control; it can either be produced in a fine, powdery condition, suitable for glass-making purposes, or it can be produced in cohering masses, which are more suitable for alkali-making, as, in this form, it is less liable to be carried over into the pan or chimney by the draught.

The sulphate produced is in a condition highly suited for the manufacture of alkali, as it is altogether free from the hard semi-fused lumps such as are too often found in salt-cake made in ordinary furnaces, more especially of the open roaster class. These lumps are very difficult to decompose perfectly in the ball furnace, cause the charge to take a longer time to finish, and are often found as kernels of undecomposed sulphate.

In comparing the relative costs of working the new "Mactear" furnace against the old form, the question of salt-supply is an important element; whether it has to be elevated from the floor level into the hopper of the furnace, or, on the other hand, it can be brought in on the higher level, and be dropped direct into the hopper. In the first case, supposing the salt has to be delivered on the floor level, as happens to be the case with the furnace at present working, then the cost of elevating will be included in the cost of the motive power of the machine.

Assuming, therefore, that in the case of both furnaces the salt is laid down on the floor at the furnace, the actual amount of labour required is, in the case of a Tyne open furnace of most modern construction, furnishing 68 tons of salt-cake per week of six days, three men per shift, or a little more than 11 tons per man per week. In the case of the "Mactear" decomposing furnace, one man per shift is able with ease to do all the work of the furnace, or about 72 tons per week per man, calculated on one ton per hour. In addition for each two or three furnaces, one man is required to look after the engines and oil machinery, and at same time look after the condensers (which require very little attention). In all, the labour may be called  $1\frac{1}{2}$  men per shift, or half the number required for the old furnace, while the output, being more than doubled, reduces the actual amount of labour per ton to about one-fourth what it is with the old furnace, the sulphate in each case being drawn into barrows or waggons ready for removal.

The amount of fuel so far has been about 4 cwt. of coke per ton of finished salt-cake; with improved draught it is expected this will be still further reduced.

The actual saving in labour, fuel, &c., after calculating liberally for depreciation of plant and interest, will amount to about 2s. 6d. per ton of salt-cake made from common salt, while to this will fall to be added, in the case of rock-salt, the actual difference in cost of the salt itself.

The effect of such a reduction, when calculated out on the cost of bleaching powder, is sufficiently striking. Assuming that 56 cwt. of salt are required to produce the acid for one ton of bleaching powder, or equal to, say, 60 cwt. of salt-cake, the actual saving would be 7s. 6d. per ton of bleaching powder, common salt being used; with rock-salt, there will be the extra cost of the salt to add to this.

The results and advantages of the new furnace may be summed up as follows:—

1. Greatly decreased cost of the salt-cake produced—say 30 per cent. saved in manufacturing costs.
2. The actual manual labour is much reduced, one-fourth the number of furnace-men being sufficient, while, as they have not to contend with the escapes of hydrochloric acid gas which are met with in the old furnaces, a class of workmen can be employed much more easily dealt with than the ordinary decomposer, who is rather apt to give trouble, and is not easily replaced.
3. The feed of salt and acid being continuous, so is the flow of acid vapour to the condenser; the supply of water can, therefore, be constant, and does not require much attention. The amount of condensing space required is very much less than with the old furnace (about one-half or less), and the acid can all be made of 30° Twaddell if required, without the use of a wash-tower.
4. The quality of the salt-cake is more uniform than that made by the old furnaces, and is completely under control.
5. Rock-salt is worked quite as easily as common salt in this furnace; none of the difficulties which are found in the attempts to use rock-salt in the ordinary furnace, or the danger of breaking the pots, are met with, and the salt-cake is quite as well decomposed; besides, as the rock-salt is free

from the moisture present in the common larger output of salt-cake is obtained.

6. Much less ground is required for the of these furnaces, and less roof space is, of necessary, while the whole is easily contrived by the foreman, whose duties are much more performed than where he has to superintend of small batches.

7. Should it be considered desirable, a natural draught can be used, and complete action effected.

A group of, say, six of such furnaces, each of turning out some 150 tons per week of salt, fed from a high level salt-store by means of simple mechanical means as the travelling used in grain stores, which shall deliver salt into the service hoppers, the finished salt-cake being discharged into waggons, which run direct to charge the revolving bladders, is what I hope are long to see at

These would be worked at a very low cost if driven from either one or two main engines, could be worked with one foreman, one man, and eight workmen at most per shift in addition to the economy in cost, the advantage of a works absolutely free from irritating fumes of hydrochloric acid compared with the present style of furnace would be obtained.

I am now preparing plans for such an experiment, and trust ere long to see my ideas out.

#### DISCUSSION.

The Chairman said he had no doubt Mr. Mactear would be willing to give any further explanation of the furnace which might be desired. He should like to know in what condition the salt and acid mixture was left the central pot—was it in a fluid state, the decomposition commenced?

Mr. Mactear said the salt and acid came in a state of mechanical mixture only; little or no decomposition having taken place. It was in very much the same state as the snow at present in the street a sludge. In reply to a question how the mixture moved from the centre to the outside of the pot the furnace was constantly revolving, and the series of stirrers, which turned the stuff over, fed came from the centre, unless it passed to the edge, the furnace would get too full.

Mr. Alfred Allhusen asked what was the stirrer; it did not appear on the drawing.

Mr. Mactear said he had not attempted to show the details fully, because the invention was in some extent in embryo.

Dr. Alder Wright had listened to the paper with interest, but he should like to ask one or two questions in connection with the construction of the furnace, more particularly in reference to the scrapers, which had almost said were the weak point of the furnace on account of their liability to break and give out. He understood that it was not yet possible to rectify them, because that was the practical difficulty which really limited the continuousness of the process. Of course, if the works were carried on for only one week, it would be essential to stop once and the repairs could be carried out then. In works where the process was carried on continuously, it would be desirable to have such

as to the length of time the pan could be kept continuously revolving, without the intermixing arrangement getting so far out of order as to deteriorate the purity of the product, by the material balling together in lumps; or for such other differences as had proved disastrous in the case of Jones and Walsh's arrangement. He should also like to ask if there was any possibility of the diffusion of acid vapours underneath the furnace.

Mr. Charles Thomas (Netham Chemical Works) asked if Mr. Mactear had yet had sufficient experience to say what the cost of repairs would be per ton of salt cake?

Mr. Mactear replied in the negative.

Mr. R. C. Clapham congratulated Mr. Mactear on the very able paper he had read. He felt some difficulty in saying much on the matter, as there were so many points connected with the chemical trade who were better qualified to deal with it. They were much indebted to Mr. Mactear for the attempt he was making to bring about a mechanical decomposition of common salt, which they would all agree was what there in the chemical trade had been aiming at for many years. They knew that Mr. Mactear had succeeded remarkably well in both the balling-furnace and the carbonating furnace, and, therefore, they were bound to receive his remarks with considerable respect. The history he had given of the chemical trade, he found rather a difficulty in entering upon it, as he could go much farther back than quoted by Mr. Mactear, for he recollected when salt was decomposed in leaden furnaces, and the many difficulties connected with it. Coming to more practical matters, there could be no doubt at all that the real point for consideration was whether the Mactear decomposing furnace differed substantially from the Jones and Walsh furnace. He recollected several years ago trying a number of experiments with Jones's furnace, and, as Mr. Mactear had said already, when it was worked for some time, the process was really very satisfactory, especially in the condensation of hydrochloric acid.

Mr. Mactear said he must have been misunderstood; he did not think Jones and Walsh's furnace was successful in this respect.

Mr. Clapham said his opinion was that it was very successful in condensation; he was not at all over-estimating the matter in saying that 20 to 25 per cent. of hydrochloric acid could be condensed by the Jones and Walsh furnace, than by the ordinary hand-worked furnace. It was very gratifying to find that Mr. Mactear could condense the hydrochloric acid without any weak condensers, or anything of that kind. He was not quite sure whether he understood Mr. Mactear to give the heats of the gases as they passed from the furnace to the condensers, and from the tops of the condensers into the air. There could be no doubt, however, that whether Mr. Mactear or Mr. Jones ultimately succeeded, what was really wanted was a mechanical furnace to work the salt.

Mr. Allhusen asked if Mr. Mactear's experience showed that any difficulty arose from the action of the acid on the brickwork on the point between the brick bottom of the reactor and the pan.

Mr. Clements thought from what he had heard tonight, this furnace appeared to be the best of any hitherto constructed. It appeared much simpler than Jones and Walsh's, and the centrifugal action produced, by which the sulphate of soda was gradually sent forward and collected, was much superior to anything that had been done previously. The means of collecting the sulphate of soda made it a continuous process, which had not been accomplished before, whilst, as they had been told that, by the analyses of the substance produced, the quantity of acid could be regulated to a degree of accuracy never before attained. If he could carry

out the improvements spoken of in his concluding remarks, by which the salt could be continuously supplied in the same way as the acid, it would almost approach perfection. He hoped he would be able to do so, and by that means no doubt the furnaces would be extensively adopted. He should like to know if Mr. Mactear used this furnace himself, and what was the quantity of sulphate of soda turned out. At the present time there were about 200,000 tons annually manufactured, and as this furnace would turn out 150 tons per week of salt cake, it would require about 1,000 or 1,200 of these furnaces to manufacture the whole quantity produced. It was always a difficult matter to get a new invention taken up, however perfect it might be, on account of the expense of introducing new machinery, but if this furnace were a genuine success there was no doubt that in time other manufacturers would adopt it, and the old ones would disappear.

Mr. Gamble said it was of great importance in the salt cake manufacture to make the process a continuous one, and no doubt Mr. Mactear would find there was a great saving in the condensing plant required, and probably also in the quantity of vitriol used. He should also like him to explain his seventh reason for considering the furnace an improvement, in which he said that should it be considered desirable a mechanical draft could be used and complete condensation effected, but he had already said that he could condense the hydrochloric acid completely.

Mr. Mactear said it was condensed to a lower point than was required by the Act, but with a mechanical draught actually complete condensation would be attained.

Mr. C. Lomas asked if Mr. Mactear did not find considerable difficulty in the caking of the salt cake, as it fell from the furnace into the troughs and ducts, because this would lead to a great difficulty in treating those substances in manufacture. It had always been found a difficulty.

Mr. Mactear, in reply, said Dr. Wright referred first of all to the scrapers being the weak point. To begin with, in the case of Jones's and Walsh's furnaces, the scrapers and the shaft were the moving part of the machine, and that principle was radically bad, because the very weakest part of the machine was made to bear the greatest resistance, so that it required the shafts to be of enormous strength. In his furnace, scrapers of any form might be used, and he was still making experiments on this point, but those he now used were very much like the ordinary stirrers of the carbonating furnaces. They were small in diameter, fixed at the end of shafts, which came down and revolved in the furnace. They had very small resistances, and the risk of breakage was very small. He did not remember in his experience of carbonating furnaces, any instances of a stirrer breaking.

The Chairman said he had known such cases.

Mr. Mactear said he had never heard of any, though of course they wore away. In the present furnace the stirrers next the pot, which was working in the strongest acids, wore away rapidly, and one about the middle scarcely wore at all, and the one working the edge in the finished sulphate, wore away a little. The quantity of work which could be done with them was certainly very large. For a wear on the end of the scrapers of about 1½ in., they had finished about 1,000 tons. The furnace had only been at work for about seven weeks in all. It had been repeatedly stopped to make slight alterations, and it was only since the new year it had been kept at work steadily. He did not think there would be any necessity for stopping for any serious repair for a long time to come, and a scraper could be put in in three-quarters of an hour. It only need be stopped while the scrapers were lifted out; it could then be started again without it; and as soon as the scraper was ready, and

hoisted up, it might be again stopped, the scraper dropped in, and in about 10 or 15 minutes operations resumed.

Mr. Osamble asked how the scrapers were made to deliver the material to the outside edge of the furnace.

Mr. Maclear said many people seemed to find a difficulty in understanding that, but it arose from this fact, that, there being a continuous flow of salt and acid, and a constant overflow, if the furnace did not deliver the stuff, it would get over-full and choke. But, partly from the centrifugal force, it did not get too full. The delivery of the furnace was absolutely an overflow. That was the principle on which he had worked, basing it on this idea, that, if he fed in the middle, it must get too full and overflow somewhere. They found it to be a mistake to attempt to force the stuff out, because then there was a danger of having the unworked stuff passing over. Dr Wright also spoke of the works going on regularly for seven days; he did not know what was the habit in Lancashire, but in Scotland, and on the Tyne, they were not in the habit of running for seven days without stoppage. With regard to the corrosion of the iron work, there was absolutely none. The whole of the iron work was painted and tarred, the lute was filled with oil or tar, and there was no escape of gas there at all. The only escape of gas which took place was from the sulphate drawn out from the hopper, and, if it were properly finished, the amount of gas which came off was infinitesimal, in fact, with sulphate, such as was made last week, there was no gas given off. During that week, they had been repeatedly getting the amount of undecomposed salt down to 1 per cent., and on average of 35 tons it was 223. The cost of repairs was, of course, a difficult question to answer, and he could not say positively without further experience, but he thought he had discounted that pretty well when he had taken it at double the cost of the carbonating furnace. The only difference was that they had in addition the central iron pot, which did not seem to wear at all, for a hard crust of sulphate half an inch thick formed round it, which apparently protected it perfectly from the acid. All the other arrangements were the same as in the carbonator, except the lute. The wear and tear on the stirrer was of course greater than in the case of the carbonator, but in assuming the repair to be double he made a perfectly fair allowance, because it must be remembered that the carbonating furnaces were doing, possibly, 100 to 130 tons, whereas this furnace would do easily 150 tons, so that if you had double the rate per ton, it more than doubled the absolute amount in money. The lute was made of iron and filled with tar or tar oil. Mr. Clapham spoke of the Jones and Walsh furnace, and said their own machinery much resembled it. His impression was that it was quite the other way. The original Jones and Walsh furnace was the one shown on the drawing, patented in 1876. In 1876 he patented the carbonating furnace, of which the present furnace might be taken as an imitation, except that that was not discharged from the centre. In November, 1879, he patented this new furnace, and in March, 1880, Jones and Walsh patented their new furnace, which resembled this one. The feature of Jones and Walsh's furnace was that they added the whole charge of salt and acid at one time, which he believed to be a radically bad principle, so far as the condensation of hydrochloric acid was concerned. The feature in his was, that it was an open mechanical furnace, working continuously, and giving up the hydrochloric acid in a slow continuous stream, which could be very easily condensed. In reply to Mr. Albans, he would say there was no difficulty at all with the joints between the pan and brickwork. After a short time they got a crust of sulphate formed on the whole of the brickwork, the edge of the pan under the bed got covered with a protecting coating of sulphate of soda, which acted very perfectly in protecting both iron and brick-

work from corrosion. It was quite true, as Mr. Clements had said, that the centrifugal action assisted the outward direction of the sulphate. He also spoke of ultimately screwing, and obtaining a continuous feed of salt in the same way as the acid, but that was not absolutely required. They had it practically, for they found, by having a ratchet wheel with pretty close teeth and a pawl which geared into them, and a lever to regulate the number of teeth to be caught by the pawl, which would force it round a given distance at each time, and so give a definite level to the screw which fed in the salt, they got a series of deliveries of so many pounds of salt at a time, which practically was a continuous feed. As to decomposing all the salt in the country, he was afraid that any patentee who should be sanguine that his furnace was going to be adopted by everybody in the trade would find himself very much mistaken. His firm intended to adopt the furnace themselves, as they believed them to be a thorough success, and, if so, he was quite sure other people would follow. The number that might ultimately be erected was a matter for the future. The saving in oil of vitriol was one on which he could give very few definite figures as yet, because you had to consider the amount of moisture in the salt and the amount of decomposition, but, as far as he could say at present, the saving was about 3 per cent. of sulphuric acid over the amount used in the close furnaces. As to mechanical draughts, the question had been put whether this could be worked in that way. He believed it could, but, if so, the quantity would be considerably reduced, and, as the amount of condensation without appeared exceedingly satisfactory, he did not think it at all likely any one would be anxious to use a mechanical draught. The making in lumps of the sulphate was a thing they had not been troubled with at all. Sometimes the furnace got into a peculiar condition in which lumps were formed, but they exfoliated and fell down almost to powder when they reached the hot region of the furnace towards the outer rim. The sample shown, which was an average of a week's work, would show that there was no lumps to incommode anybody. In another sample there were a few lumps, but they could very easily be crushed.

The Chairman said they must all feel very much indebted to Mr. Maclear for his valuable paper, and the presence of so many gentlemen from different parts of the country interested in the alkali manufacture was proof of the interest his paper had awakened. This was another illustration of what seemed to be the revolutionary period of the alkali trade. Some years ago they were under the impression that Mr. Jones had solved the problem in this difficult matter of decomposing furnaces, and they were all pretty sanguine that the Jones furnace would be universally adopted within a few years. Mr. Maclear had explained how those hopes had been disappointed, and that there was still room for the application of enterprise, mechanical skill, and chemical knowledge in solving the problem of an effective decomposing furnace. They must give Mr. Maclear credit for his courage and enterprise in carrying out what he feared must have been only experiments in striving after perfection. There was no doubt that the continuous process was the thing to aim at, it possessed all the advantages which Mr. Maclear had claimed for it in the regularity of the product, no doubt in economy of material, and certainly in the facility of condensation, because the regular emission of the muriatic acid which had to be condensed was the most essential condition of complete condensation. He should also think it extremely likely that the process would be attended by a saving of acid. This paper was a contribution to a very interesting question which touched all departments of industry, viz., the limit of the economical application of machinery. Some one had

it would never pay to get a machine to pick off a field and put them all into one corner; as an extreme case. The real problem Mr. Macartear was attempting to solve, was whether this ration to which machinery could be successfully applied. They all wished to replace unskilled machinery, but it did not always turn out as it should be done profitably, because there was an element of repairs, and the necessity for it in the working of the machinery. He was going to suggest difficulties which Mr. Macartear might find in the course of working the invention, for he had no doubt he was able of them himself, without any one disabuse with additional ones. As he had already experimented was of the greatest value and he knew that in another direction they were having a similar experiment, because Mr. Macartear was attempting a furnace on a very large scale, new principle, to the results of which they were looking with great interest; and perhaps Mr. Macartear would, at some future time, give them his views in a paper. Mr. Macartear's process might be as one in which the batches were of no size at all; it was continuous; but Mr. Allhusen was trying the same problem, where the batches were on a scale altogether unprecedented, they would be able to see which plan was the best. Meantime, the more cautious or manufacturers would go on in the old way, keeping their minds perfectly open to receive any quarter. He was glad that Mr. Macartear's interesting retrospect, had given credit to the grandfather of the gentleman now that most important invention, the application of heavy cast-iron pans in which to decompose that had held its own, and would continue until Mr. Allhusen or Mr. Macartear showed that better could be attained. Mr. Macartear had the very severe labour of the decomposing, but his impression was that these men made much of it; they turned over a smaller quantity for a day's work than any other class of men who worked at furnaces, giving as an excuse which they were occasionally exposed. No Mr. Macartear succeeded in getting a gas-tight at would be an additional recommendation.

He quite agreed with Mr. Macartear as to the success of working, but the degree to which they were complied with must be determined by

If rock salt could be used, that also would be advantageous. He presumed it was the long-continued with the acid which made the decomposition of rock salt effective, which was not possible in the present state. There could be no doubt about the saving

It went rather against the grain to see a man working a machine, working a heavy machine, and they were to see men better employed—they would be watching a machine than acting as one; same in the question he had before alluded to it where you could replace brute force by machinery economically with more skilled labour to He concluded by moving a vote of thanks to

of thanks having been passed,

Macartear, in responding, said there was one question forgotten to notice, viz., as to the condensing they could not give the exact number of cubic feet, but they were doing two and a half times the work of the condensers which they could do in the same space connected to the old muffle furnace. After all, it was that of repairs, and that could only be determined by experience. He had assumed the cost of the condenser to be double that of the carbonating furnace, and if done that, and having loaded the cost with

20 per cent. on the capital for depreciation and interest, there was still 2s. 6d. per ton to the good. Now, even if we were to assume there was another 1s. of that required for excessive repairs, and it would still leave the furnace economically successful. The Chairman said, "If he could produce a furnace which was gas-tight," but that he had already done, there was no question about it, and the same with regard to working rock salt, for he had shown them a sample of rock salt, about 100 tons of which had been worked with perfectly good results. The delivery of salt cake direct into wagons for the balling furnace was of course a comparatively simple matter; and when laying down new works it would be comparatively easy to elevate the sulphate direct from this furnace into the hopper of the black ash furnace, weighing it on the way. It was in such a comparatively fine state of division that there was no difficulty in dealing with it.

### FOREIGN AND COLONIAL SECTION.

Tuesday, February 1st, 1881; Sir RICHARD TEMPLE, Bart., G.C.S.I., C.I.E., D.C.L., in the chair.

The paper read was—"The Industrial Resources of South Africa," by Sir Henry Bartle Frere, Bart., G.C.B., G.C.S.I., D.C.L., LL.D.

In order to obtain the final corrections of the author, the publication (at his request) has been delayed until next week, when a full report of the paper and discussion will be printed in the *Journal*.

The Chairman, in introducing the subject of the evening to the meeting, recalled to the memory of the members the circumstance that the African Section of the Society was opened, some years since, by Sir Bartle Frere, in an inaugural address, which is printed in the 22nd volume of the *Journal*. He was sure it would be a great delight to all members present on this occasion to welcome Sir Bartle back again amongst them, after the arduous task he had since then had to perform, and that it would also be a great satisfaction to the Society to receive the results of so large a practical experience in the affairs of South Africa, in the form of the paper, which would now be read.

Sir Bartle Frere then proceeded to give an account of the present state of the various districts of South Africa, comprising the old Cape Colony, including Kaffraria, Basutoland, and Griqualand West; the colony of Natal; the Orange River Free State; the Transvaal; and the Transgariep and Damaraland. He spoke of the mineral resources of each section of the land; of the agricultural industries; of the harbours, telegraph lines, railways, and of the recent rapid development of steam navigation; and he finished his address with a special allusion to the condition of the large population of native races that is still spread over the land, and to the necessity which this implied for good and strong Governments over them, if any effectual advance is to be made in the direction of a permanent civilisation for them.

After the reading of the paper, Viscount Sidmouth asked some questions regarding the harbours of South Africa. Mr. Jones exhibited some specimens of the diamonds of the Griqualand districts on behalf of Professor Tennant. Sir Bartle explained there could be no doubt Delagoa Bay was a magnificent harbour, and capable of being connected with the Transvaal by a short line of railway. Sir David Tennant, the Speaker of the Cape House

of Assembly, substantially confirmed the account given by Sir Bartle of the capabilities of the place, and described the extent of country which is already opened out by railways. Dr. Badger wished that it were possible some near neighbours of England, who were dissatisfied with their lot, could be got to understand that there was a good field for prudent industry in the land, described in the paper. Mr. Robert Rawlinson remarked upon the opening out of roads and the peculiarities of indigenous labour. The meeting terminated with a vote of thanks to the author of the paper, which was proposed by Sir David Tennant, and seconded by Mr. Peace.

#### NINTH ORDINARY MEETING.

Wednesday, February 2nd, 1881; ROBERT GIFFEN, Chief of the Statistical Department of the Board of Trade, in the chair.

The following candidates were proposed for election as members of the Society:—

Bridge, John, F.R.G.S., Marlborough-house, Sale, near Manchester.  
Cochrane, Vice-Admiral the Hon. Arthur A., C.B., United Service Club, S.W.  
Collingwood, Lieut. William, The Limes, Cheshunt, Herts, and India-office, S.W.  
Fisher, John, 43, Mincing-lane, E.C.  
Hall, William Shipley, 79, Cannon-street, E.C.  
Haslam, Alfred Seale, Duffield-road, Derby.  
Helder, Augustus, Corkicle, Whitehaven.

The following candidates were balloted for, and duly elected members of the Society:—

Barker, George E., Sutherland-villa, Chiswick.  
Barlow, Walter Alfred, 6, St. Paul's-churchyard, E.C.  
Buchan, William Paton, 21, Renfrew-street, Glasgow.  
Burt, Frederick, F.R.G.S., Woodstock, Crescent-road, Crouch-end, N.  
Temple, Sir Richard, Bart., G.C.S.I., C.I.E., D.C.L., The Naah, near Worcester.  
Tovey, Major Hamilton, R.E., Waltham Abbey, Essex.

The paper read was on—

#### TRADE PROSPECTS.

By Stephen Bourne, F.S.S.

It has often been remarked that trade moves in cycles, depression and elevation alternating and succeeding each other at intervals, not indeed of exactly the same duration, but with such approach to regularity that at any particular period we may, with some pretension to accuracy, predict what is likely to follow within a short period of the time at which the observation is made. It is generally found, too, that activity is not confined to one or more countries; but, unless some special cause intervene, that prosperity or adversity pervades the whole trading world at very nearly the same time. The moving cause may originate in one place or in one branch, but it soon becomes more or less diffused; and this will necessarily become the more marked as rapidity of communication and facilities for transport are extended. The

duration of these cycles is supposed to ten or eleven years, and, starting with commencement of the present reign—i following upon severe banking and commercial embarrassments in the United States in preceding year, there was a panic in London that 1847, the year of the Irish famine one in which, after the collapse of the mania of 1845, the commercial panic attained its height. In 1857, again, succeeding the Russian War, and that in Indian Mutiny broke out, the Bank Act suspended. In 1866, there was a panic commercial and joint stock companies, the which exercised a fatal influence upon the the three following years; and since the there was severe depression, from which the did not commence to emerge until the 1879.

Between each of these dates there came of great commercial and manufacturing producing an inflated condition, to be succeeded the next wave of depression. It may however, that, as might naturally be the interval between the height of one and the depth of the other has generally shorter than that of the following. When once the tide begins to rise, it flows rapid progress, then descends rapidly, as a long ebb, or at least a slight flow, the event or condition of things sets the speculation moving, renders everything for a time, and then, having exhausted it collapse ensues. The rise of the last commenced soon after the termination of the German War, in 1871, proceeded with rapidity through 1872 to 1873, and had descended much in 1874; but 1875-6 were deep depression, those of 1877-8, with eight months of 1879, remaining at a very The first indications of revival were of August, 1879; and though there have been down—rapid transitions since then—been a well-sustained general improvement the year just ended, seeming to justify still further progress which may lead greater inflation than any we have before. The present condition of trade, and the offers, is the subject with which it is peculiar on this occasion.

England is so essentially a manufacturing trading community that, notwithstanding may be distress in other of her interests these are progressing well, the country may be prosperous; at least, it wears the being so, notwithstanding that, as at the agricultural interest may be suffering. The United States, on the contrary, is so an agricultural nation that, even when the tion of her manufactures is not encouraged, on the whole, be said to be flourishing. Therefore, without in the smallest degrading the importance of our agriculture, of first importance must be given to our which manufactures form an important. Herein lies a real difference between the Kingdom and the United States, that the large trade irrespective of her manufactures the trade of the other is principally in her own productions. British merchants

sing for our own need or selling our own, deal with and in the produce of every part of the world, whilst at present—we do not say that it may be so—American traders are employed with the interchange of goods which she produces for sale, or imports for consumption. Almost everything that is grown or raised in a market here, and, what is of immense importance, may be made the means of raising the value of the state of the market suits for or against a sale. It is through this that we are so much concerned with the welfare of every land—and in their prosperity or are partners in their prosperity.

But, in the widest acceptance of the term, the home trade may be divided into two separate branches, the home and the foreign—which, though closely connected and greatly dependent upon each other, often very differently circumstanced and under a greatly differing influence on the general economy. The profits of the home trade depend upon its activity, and they do not add to the wealth of the country as a whole. That wealth, so far as it arises from home industry, is the surplus value of that which labour produces, after that which is the support of the labourers consumed is deducted. If, as on a former occasion\* I attempted to show, every worker does, on an average, produce as much as suffices for his own support and that of the non-workers dependent upon him; and of that which he produces may become the object of trade, and, unless wasted or consumed, be so much additional wealth to some other person. Its transfer from hand to hand by the means of money, through whom it passes, though profitable to the individual, or more of these, does not make it any the more valuable as a contribution to the wealth of the nation. Not so with our foreign trade. What difference of value there may be between an article brought hither, and that with which it is paid for, if on the right side, so much added wealth; if on the left, so much lost; and, in a permanent shape; indirectly so, summed in the sustenance of those whose labour produces something. But, once imported, it can give it additional value to the country; for, though one man may gain, it is at the expense of another. Home trade is the source of acquired wealth, and betokens, by its activity, the existence of prosperity. Foreign trade, on the other hand, supposing it is not a losing one, is the result of prosperity. For this reason, then, it is the subject of foreign trade which demand the consideration. One more distinction it is necessary to draw, that between the trade itself and the traders by whom it is carried on. Ordinarily, the trade is good, the trader profits by it, but not necessarily so. A merchant may purchase a quantity of cotton goods with so much money, expend much more upon conveying it to a foreign market, and there sell it at a loss. He may have added the proceeds to be expended in purchasing wheat, which, when it reaches him, may be worth less than it has cost him, and so make a loss; yet, after all, the wheat, when it is sold, may be of more value than the cotton goods sent away. The country has been a loser, though the trader has been a loser. It is in or loss which accrues to the country from

this trade which it is proposed to consider, not that which pertains to the individual trader.

Again, our foreign trade must be divided into export and import. There is no need here to raise the much vexed question as to which of these it is that best evidences the prosperity of the country. That has been fully examined in a paper on the "True Relation in which Imports should stand to Exports;" but, in the belief that, in the present condition of the country, it is the exports on which our trading prosperity depends, they will, in the first place, occupy attention. This opinion receives striking confirmation from the following figures, commencing with 1872, admittedly the year in which the inflation of trade reached its greatest expansion, when, also, our exports of British produce and manufactures attained a higher value than any previous or succeeding year has seen, whilst our imports have not progressed in the same sequence. The goods exported, after having been previously imported from abroad, are excluded from both sides of the account†:—

	Exports.	Imports.	Excess of Imports.
	In Million £'s to Two Decimals.		
1872	256·26	296·36	40·10
1873	255·17	315·45	60·28
1874	239·56	311·99	72·43
1875	223·47	315·79	92·32
1876	200·64	319·01	118·37
1877	198·89	340·97	142·08
1878	192·85	316·14	123·29
1879	191·53	305·74	114·21
1880	222·81	350·00 (F)	127·19 (F)

As trading prosperity waned so did the amount of our exports fall off, as it waxed so have they begun to increase. They have not yet reached the level of 1872, but a growth similar to that which has taken place in the last year, would bring the present one up to almost the exact amount of 1872, the decade thus ending as it began.

A somewhat closer examination of these figures is necessary for an estimate of their true import. It would be tedious to go through all the various articles of export, and this having been done elsewhere, the result has been to show that, taking the three great industries of cotton, wool, and iron, the teaching they afford does not differ from that of the whole. It will be sufficient to take the three years—highest, lowest, and last—thus:—

Exported.	1872.	1879.	1880.
	£	£	£
Cotton manufactures ....	80·13	63·97	75·56
Iron, including hardware } and machinery }	49·35	29·73	41·08
Woollen manufactures ....	38·49	19·57	20·60
	167·97	113·27	137·24
Per-centage of whole exports.....	65	59	62

With these amounts, it may be useful to compare

\* Same volume, pp. 162-192.

† The tables throughout are constructed in millions to two decimals: thus, for 256·26, read 256,260,000.

the quantities, so far as they are shown in bulk in the published returns, viz :—

Exported.	1872.	1879.	1880.
Cotton piece-goods (yards)	3,535·16	3,724·55	4,496·34
Iron and Steel (tons) . . . .	3·39	2·88	3·79
Woollen piece-goods (yards)	384·82	232·90	240·0

This comparison brings out the fact that, whilst the quantity of cotton piece-goods is larger in 1880 than in 1872, by 25 per cent., the money value is actually smaller. For the same years, the price of the raw cotton imported having been in 1872, 68s. 5d.; 1879, 55s. 1d.; 1880, 55s. per cwt.

The tons of iron exported were 10½ per cent. more in 1880, the money value 21 per cent. less, the price of pigs being, in 1872, 102s. 2d.; 1879, 45s. 2d.; 1880, 63s. 10d. per ton.

The quantities of woollen piece-goods had fallen 42 per cent., the money value 46 per cent., whilst the price of the wool imported was—1872, 1s. 2·3d.; 1879, 1s. 2·5d.; 1880, 1s. 1·6d., per lb.

The inference to be drawn from these variations is, that in each class of goods the profits realised by the sale must have been much smaller in the last year than they were in the first of the three periods.

A glance at the values of our imports given above, will show that their amount, in the several years, does not vary with the degree of trading prosperity. In this they differ from the exports, and for more than one reason. For our exports we get the best price we can, and if the markets to which they are sent run low, we must be content with small profits or none at all; whereas, with the imports, we must buy largely for our own sustenance, and if the prices are high we are compelled to pay them. The supplies of food we need depend much upon seasons of fertility or otherwise at home, but are steadily increasing with the growth of our home population; the whole of which increase must necessarily be thrown upon foreign sources, since we grow less by more than one-half than suffices to feed the existing numbers. Three classes of articles may be selected to illustrate the relation which these bore to the whole, in the same three years as were taken for the exports, thus :—

Imported.	1872.	1879.	1880.
	£	£	£
Articles for consumption as food and beverage . . . . .	148·25	173·97	187·20
Materials for textile manufacture . . . . .	92·40	73·11	84·23
Other manufactures, &c. . . . .	50·79	46·81	61·82
	291·44	293·89	333·25

These figures disclose the fact that, whilst our food imports, as between the period of the highest prosperity and revival, 1872 and 1880, have increased 26 per cent., and other articles 22 per cent., there has been a decline of 9 per cent. in the value of the supplies taken for the support of our textile manufactures. But if the comparison be

made between last year and its predecessor, it be found that all have increased in the proportion of 8, 32, and 15 per cent. respectively.

A point of considerable importance, as regards the indications these figures afford of general prosperity, is to ascertain whether these incomes owe their existence to the sale or purchase of quantities or at higher prices. A series of elaborate calculations into the values of 1871, 1880 give these results as to the exports, the gains in the value is due on :—

	Cotton.	Per cent.	Wool.	Per cent.	Iron.
To volume of exports	£ 9·01	83	£ 69	70	£ 6·16
To price at which sold	1·87	17	·30	30	2·70
	10·88		·99		88·6

From this it would appear that the additional profit obtained by our cotton manufactures (per cent.) has been, proportionately, far less in our iron or wool, in which the relative volume to value is exactly the same—30 per cent. So with our imports, the additional values in one year over the other have arisen, in—

	Food.	Per cent.	Textile Materials.	Per cent.	Other.
From volume of imports	£ 5·23	40	£ 7·22	65	£ 10·50
From price of imports	8·00	60	3·90	35	4·51
	13·23		11·12		15·01

Showing that, to the higher cost of our food we owe 60 per cent. of the increased payment, and the other classes only 35·30 per cent. This is important, seeing that the one is consumed and the others are, to a considerable extent, recovered in the prices obtained on the sale of the manufactured goods.

Putting together the whole of the articles which have been included in these calculations—being the principal ones that, from the nature of the information supplied, admit of such investigation—it will be seen that of exports, to the value of £203·12, in 1880, the excess over 1879 was £26·26, of which £18·68 was due to greater quantities, and £7·58 to higher prices. Of imports of foreign goods, to the value of £333·25, the excess was £39·36, of which £22·95 was due to greater bulk, and £16·41 was due to greater cost. That is, that for the extra receipts for imports we had to give 71 per cent. more in value, whilst out of our extra payments for imports 58 per cent. went for additional bulk.

From what has now been said, it is evident

has been, during the past year, a real and vital revival in the export trade of the country, accompanied by a still greater expansion of imports. The real start in both, from the point of 1879, is really greater than has been seen; for the turning point having been in the latter part of that year, the gains in the latter part of 1880 hide some of the losses in the former. This may be shown by altering the period of time to which the twelve months are compiled,

	Total Exports.	Imports.
ending 31st July..	£214·24 ..	£404·31 ..
„ 31st Dec...	222·81 ..	409·99 ..

proceeding in an attempt to forecast the progress of our foreign trade, from the evidence afforded by the past, and especially the last, it may be well to inquire somewhat of the condition of the home trade; premising facts being much more difficult to ascertain, as they give are inferential rather than

extent to which cotton has been manufactured for home use in the three several years, it is able to form a tolerably correct judgment. Acting from the weight imported the goods exported in the raw condition, and then acting at the generally accepted rate, of five the lb., we can guess at the quantity that during the year, been absorbed in the manufacture of goods for domestic consumption. Thus—

	1872.	1879.	1880.
	cwts.	cwts.	cwts.
Wool imported ....	12·64	13·17	14·55
Wool exported ....	2·43	1·68	2·01
Wool in this country..	10·21	11·49	12·54
Woolen goods exported	6·30	6·60	8·00
Woolen thread .....	2—	2·20	2—
	8·30	8·80	10·00
Wool for home use ....	1·91	2·69	2·54

It is thus reason to think that the home trade cannot have been greater during the past year than in the previous one, though both certainly exceeded that of 1872. As regards the progress of woollen manufactures, we are not able to calculate so closely, but some indication is afforded by the quantities of the raw wool imported and exported.

	1872.	1879.	1880.
	lbs.	lbs.	lbs.
Wool imported .....	380·80	500·20	568·37
Woolen yarn exported....	184·91	292·40	281·02
Wool for use .....	195·69	207·80	287·35

It is not possible to estimate the weight of wool used in the manufacture of the goods exported as these, in 1880, have not, in the quantity exceeded those of 1879, by so large a pro-

portion as the raw material retained for use in the latter years has done; there is room for supposing that there has been a greater consumption at home, although the trading reports scarcely bear out this supposition.

Coming next to the iron industry, the raw material for which is principally of home production; we find that the impetus given to manufacture for export, has induced a more than corresponding increase in the number of furnaces put into blast, and hence the manufacture of a larger output. It has been estimated that the quantities may stand thus:—

	1872.	1879.	1880.
	tons.	tons.	tons.
Pig iron produced.....	6·74	5·99	7·20
Importation of iron ore .....	·80	1·08	2·63
Exportation of manufactured iron	3·39	2·88	3·79

It is generally admitted that the stocks in hand are larger than they were last year; and, if so, it is difficult to see how there can be such a greatly increased demand for home consumption as is supposed. There can, however, be no doubt that the additional number of ships known to be on the stocks, or recently off them, must have required more iron for their construction. It is significant, too, that the exportation of iron in December last was some 22,000 tons less than in the same month of 1879, and that the stocks in bond in the United States, which has been our best customer of late, are greater than they were.

Another feature, which is generally and rightly taken to indicate the briskness of trade, is the amount of railway traffic receipts, which, as published, have during the past half-year amounted to £226·27, being an increase of £1·01 on the corresponding period of 1879. This, however, must not be attributed wholly to the home trade, for the carriage of goods, especially iron to the ports of export, and the transport of grain from the ports of import, will have added largely to this extension of traffic.

The London Clearing-house returns again are evidence that something which is worth money is passing from hand to hand. Yet this may not be so much from trade in goods as from speculation in funds, stocks, and shares, as may be inferred from the very large figures of settling days—1879, £4,859· millions; 1880, £5,716· millions.

Any review of our trading position, or attempt to estimate its progress during this or following years, must be incomplete if attention be not paid to the state of our finances. The low rate of interest at which money is to be lent, and the high price at which Consols or other stocks are to be sold, may evidence either that trade is so profitable as to provide large surpluses for investment, or so contracted as to leave little room for the employment of capital already acquired. As a rule, however, when trade is brisk, money is dear, and cheap in times of limited employment. This has been and is the case in the last and the present years, and the gradual hardening of the market induces the belief that money is now finding employment in trade rather than in fixed investments. Yet, it will not be safe to rely too much

upon this as evidence, for, with increasing facilities for interchange of money securities and credits, the plethora or scarcity of available money in this country may be affected by circumstances other than those of trade, at home as well as abroad. An attentive survey of the state of the money market, as evidenced in the Bank rates, the stocks of bullion held by the Bank, the prices of the public funds and other securities yielding a fixed income, at the different periods of our commercial history, cannot fail to throw much light upon our trading condition at the present moment, and its probable progress in this and following years. But this subject is so much complicated by the operation of political movements in other countries as well as our own, and influenced by a variety of other causes, into which there is not time now to enter, that it must be passed somewhat lightly over.

The mere fact that money is plentiful or otherwise in New York, Vienna, or Paris instantly acts upon the available supply in London. Nor is it possible at all to ascertain where the money employed in any one trading or mercantile centre is really owned. Thus, English mercantile bills are constantly discounted in Paris and *vice versa*, just as the current rates of interest in the one place or other may make the process easy to be effected; and purchases of English funds or stocks may be made on American account without any movement of either bullion or goods. There is reason to believe that, during late years, when the balance of trade between England and the United States was increasingly against us, American securities held in England were largely bought back in payment for our excess of imports; and, though now it is stated that very large purchases of American railway and other stocks have been made here by *bona fide* investors, it is difficult to see how the purchase-money has been transmitted to the other side of the Atlantic; seeing that a comparatively small amount of bullion has been sent over, whilst our obligations for imported food have been very large. Judging by present appearances, it would seem that there is no lack of money for trading purposes, or for increasing means of manufacturing articles for export, but very little disposition to put it fully to such uses; thus evidencing very little confidence in any great expansion of trade being about to arise.

Too much stress has been laid upon the great rise in the prices of all public securities, which is variously stated to have been 15 and 17 per cent. within the year, equaling upon three to four thousand million pounds sterling—the estimated amount held in the United Kingdom—an addition to capital of 450 to 600 millions, and this is spoken of as though it rendered the country actually more wealthy. No one really believes that the country's wealth has thus increased. An individual holder, or even a number of such, seeking to realise investments, may now do so to an advantage; but let the whole, or even a large number of such holders seek to turn their stocks into money, and prices would immediately recede. Yet this nominal growth of wealth is, to a great extent real for trade purposes. Bankers and others will lend on such securities more when they are high than low, or, at any rate, their owner can obtain more credit with which to traffic. It is

this credit that creates so many fluctuation trade. A belief arises that more goods will be required for exportation or consumption, forthwith purchases are made, in the expectation of selling again. Prices go up, as willing to increase, until it is found that the real demand is small, and forthwith there is a rebound. This has been evidenced in the transactions of 1872. Orders came from America for iron, principally the form of rails, or pigs to make rails; production was increased; prices went up, then fell, and have partially risen—to fall, it is probable, still when it is found that the demand has slackened or ceased. This demand really arose from causes: the excessively low figure to which prices had fallen, and the lamentable deficiency in our late harvests, which rendered large purchases of grain necessary. The ready sale of American agriculturists found for their produce induced the belief that extended cultivation would be profitable. To do this, additional rails were necessary, and, our rails being cheap, instead of money, were taken in payment. This saved us from the expected drain of bullion at the time, and, should our harvest this year prove good, may save us from it altogether. If so, anticipated expansion of trade with the United States will not go on for any length of time. Other causes have acted in a similar manner in other branches of trade, as evidenced in the following figures, showing the destinations of our national exports during the twelve months ending 30th September last, as compared with the same countries in 1872 and 1879.

Value of Exports.	1871-2.	1878-9.	18
	£	£	
To United States .....	40·53	16·30	1
„ British India .....	22·37	23·64	1
„ China and Japan ....	11·34	9·28	1
„ all other countries ...	173·02	138·32	1
Total .....	247·26	188·04	2

Thus the increase in our exports in the one year was:—

To United States ..	£ 15·19	=	90 per cent
„ British India ..	7·51	=	32 „
„ China, Japan ..	3·05	=	3 „
„ „ Other countries	4·59	=	3 „

The similar figures for the year ending December last, are not yet published. The total, however for the year, as found in the monthly returns £222·81, or £4·43 above that for the twelve months ending in September, that being the excess of the last quarter of 1880 over that of 1879. The proportion of this excess will, probably, be found to be to India; and some to Australia and Canada with whom our trade has been little of late. Yet, even when this is added, it will still be how limited has been the area of enlarged trade. The “other countries”—that is, all the world besides, America, India, China, and Japan—have sent from us 143 millions out of 218, have made no further, increased their purchases by more than 5 or 6 per cent. Nor does this represent a

trade, since the general rise in prices will account for some 4 per cent. of the additional value, leaving the quantities of the goods much as they were before. With one-third of our customers we have done better business in 1880; with two-thirds it has remained stationary, even during the recent expansion; whilst, as compared with 1872, it has been worse, by from 20 to 25 per cent.

These are serious considerations as regards the anticipations which are to be formed for the future, and should enforce the utmost caution in all trading and manufacturing engagements. Yet it is to the poorer countries, those which have not yet become peopled, or, if peopled, where arts, manufactures, and commerce have yet to be introduced or developed, that we must look for any permanent or profitable increase of trade. It is to these we should send our capital and labour, if we would seek new markets or raise up new customers.

History, it is said, repeats itself, and if trade prosperity is to proceed as in former times, the cycle must be near its end, and the advent of its highest point be at hand. It is necessary, therefore, to study the course of the past fall and rise, that we may know how and when we may expect its completion.

It also would seem to be the general expectation of all who are engaged in trade. Most of the circulars issued at the commencement of the year mark of the past 12 to 16 months as those in which there has been much fluctuation, but withal growing improvement which promises to become fully developed in the months or years soon to follow. The late depression has been longer than predecessors, and from this it is inferred that revival will be more rapid. But such repetition of boom or never is complete in all its features, and may be well to look also at the points in which the present condition contrasts with that of the past during which the last flood was running.

In 1870, the exports of British produce and manufacture rose but ten millions; in 1880, they increased more than thirty; whilst the imports required for home use, in 1870, were only swelled by some ten millions, whereas in 1880 the addition has been to the extent of forty-five millions of money. The total imports retained may be thus divided:—

	1870.		1880.
Food.....	100	..	185 (?)
Raw material.....	119	..	120 (?)
Manufactured .....	40	..	45 (?)
	259		350 (?)

In 1870, our imports exceeded our exports by £59 millions, in 1880 by 127. In 1870, we had had in session three of the best harvests ever known; in 1880, with one exception, six of the worst. In 1870, the population which produced our 200 millions of exports, and consumed the 100 millions of foreign supplies of food, was 31 millions; in 1880 it probably have numbered 35 who were only able to export 222 millions, whilst consuming 185. In these respects the condition of the country was very different from that of the present time, and seems impossible that trade should run the same course.

Again, 1870-1 was the year of the Franco-German War, which—whilst it rendered both countries in large measure dependent on this to supply their wants—paralysed their own trade, and

lessened their powers of production. Now, ten years of peace has enabled both of them greatly to increase their trade, and that in many articles which rival ours. America was scarcely beginning to recruit the resources wasted in her civil war. Now she is entering upon a competition and race with Great Britain, the keenness and fierceness of which promises to exceed the wildest expectations which could have been entertained ten, or even five, years ago. The power of supplying the wants of the world has increased in greater degree than those wants have grown, or rather than the means of paying for their supply have expanded; and we have not preserved our relative superiority in producing power.

To take another view of the case; in 1870, we were at peace with all the world; we have now to meet the cost and overcome the disorganisation resulting from contests in India and the Cape; from the decay of the Turkish Empire, the trade with which was, to us, formerly, a source of the greatest profit; and, however soon the condition of Ireland may change, there can be no doubt that its present state is entailing losses which must have an effect upon our commercial progress.

All these considerations should check any exuberant hopes that the inflation of 1872-3 is about to be revived. The progress already made during the past year has been very spasmodic. Of this no surer token can be adduced than the fluctuations in the price of iron, the article of our trade with which the revival commenced, and on the continued demand for which much extravagant expectation has been based. It is but too evident that speculative action drove the prices of this and other things far higher than the extent of the trade in them warranted; and though at present prices may be at a fair level, they are not so high as to yield great profits. Any permanent increase in cost or selling price would, in all probability, put a check to demands which, there is reason to believe, grew out of exceptional circumstances not likely to exist for any length of time.

It is the undue influence of this speculative element which threatens to revive the fatal inflation of 1872-73, for though during that period there was much real accession of wealth to the country as well as to individuals, there was still more that was false. Since then, and as the result in great measure of the course then pursued, there have been sad and heavy losses; not solely to the wild speculators the cessation of whose butterfly term of prosperity there is no reason to deplore. In such seasons the hard-earned savings of the prudent and careful, the provision made for widows and orphans, become placed in the hands of financiers, who unduly stimulate trade, only to prepare the way for renewed depression, and for all the misery which such catastrophes as the Glasgow and West of England Bank failures inflict upon the undeserving sufferers. Yet, altogether undeserving many of those who suffer can scarcely be said to be. It is the speculative spirit which seems to possess so many of all classes, that opens the door for those who thrive by its existence and cultivation. Since 1872, the number of these, and the boldness of their flights, have vastly increased, and it is painful to see how constantly the writers on trade subjects speak of speculation, as though it

were the legitimate basis upon which the expansion of trade is entitled to rest. To judge by present indications, if trade does so rapidly revive, it will have very little firm ground upon which to stand. There is really nothing more solid to justify the extravagant anticipations so generally formed—nothing more likely than this speculation to wreck the prospects which may be safely entertained, that a gradual, though slow, improvement may be maintained.

What, for instance, are the prospects that our trade with America will, next year, exceed that of the last? She found us in want of increased supplies of food, owing to our bad harvests; and from her extended agriculture supplied our wants. She found, too, that our iron trade was suffering great depression, that prices were so low as to permit importation into her country profitable, even under prohibitory duties (levied as such, more than for revenue purposes). We purchased her corn at good prices, and paid for it with iron, sold at the outset at poor prices. Believing that this state of things permitted of continuance, and flush of means from her profitable exports, she determined to lay down rails, to enable cultivation to be extended further inland; thus taking off our hands accumulated stocks, and even new supplies, at prices which became, as they went higher, the stimulus to further production. Unless, however, in the meantime, new openings for trade can be found, it is not at all probable that this will continue. A good harvest at home, should we have one this year, will leave much of the grain now growing for our market as surplus stock in the hands of the Western growers, and thus prevent the continuance of the purchases from our manufacturers which has had so much to do with sending prices up. Should this be the case, it may, in the end, not be disadvantageous to us, for so soon as agricultural production in that country exceeds the demand, or from other causes prices fall so as to be less profitable, the growers there will become unwilling to protect, their various manufacturing interests, at an excessive cost to themselves, and thus bring about the reduction or abandonment of prohibitive or excessive duties. This is the direction in which we may look for the growth in America of free-trade principles, the establishment of which must, sooner or later, be consummated. This may, for a time, be allowing our manufactures to come into competition with her own; but the progress she is making in the neutral markets of the world forbid the hope that she will long allow us to hold our ground where our products have hitherto predominated, still less increase her internal consumption of those imports which she has in herself the power of producing. The figures already quoted show that our exports thither are not on the increase, and when the next quarterly return of values appears, it will probably show that the trade with her in our own manufactures has already begun to decline.

If we turn to India, the country which, next to the United States, has contributed most to the revival of our export trade, the prospect is more hopeful. Yet, even there, the recent exports must be deemed exceptional. During the famine, her power of purchasing was limited; much that has been sent there during the past year has been to supply previous deficiencies, and it is understood that stocks of cottons are accumulating. Two-

thirds of our exports thither consist of manufactures, and though it may not be time to come, it is not probable that India the raw material on the spot, and with labour much cheaper than here, will, any more than America, fail to manufacture for herself. The greater likelihood of her requiring larger quantities of iron to extend her railway system, though she must come slowly; but the capitalist who now erects cotton mills with the intention of manufacturing more largely for Indian customers be guided more by faith than reason.

The third principal quarter from which orders for our manufactures have come is China and Japan. Here, again, far more than the handicrafts these countries take from us are cotton pieces and yarns—a trade which is likely to continue, and may greatly increase. At present there seems little opening for selling them in great quantity, but so intelligent a people are the Chinese, to see the advantages of railway communication; and unless we are beaten out of the market by our neighbours in Belgium and Germany, there is every reason to anticipate that these people will prove extensive customers. There is no doubt, however, in the belief that when that day will be accompanied, or preceded, by such an influx of the Chinese labourers as may seriously compete with our own workers, in our own places of production.

It is exceedingly unsatisfactory to find that Australian colonies have contributed little to the recent growth of our exports. Canada has done much better in 1880; but then in 1879 was depressed, which she fell off in her demands for our goods. There seems but little reason for hoping for a great extension of trade to these colonies, unless it speedily take place. The South African Republic must receive a severe check—excepting the necessities expended in war—from what is, taking place there.

So far, then, as the present outlets for our manufactures of our mining and manufacturing industries are concerned, there would appear to be no solid basis on which to hope for any great extension of our trade in the present or coming year. It may even be that the revival has reached its height, unless wild speculation attempts to throw goods on markets in advance of their requirements.

It will be gathered from what has been said, in connection with his previous expressions of opinion, accompanied by copious compilations of figures, that the writer sees but little chance for the rapid extension of the import trade; and he sees nothing to regret in the fact that the month's official returns manifest, that our expansion has received a check. The figures of the coming year will possibly prove this to be something more than accidental or temporary. Without again going over the ground already trodden on former occasions, it may now be said that he sees no reason to doubt the soundness of two arguments, which he thinks the history of the past decade should remove from the realm of controversy—namely, that a continued growth of imports, unaccompanied by a corresponding increase in the exports, cannot be an evidence of increasing wealth; and that it is by no means satisfactory to find that the whole value of our exports does not deduct the cost of foreign materials which

in manufacture, now falls far short of the have to pay for the food which our population requires for its support. Further, as our increasing population fails to find over the unoccupied and uncivilised which is ready for cultivation; and continues an unprofitable expenditure of substance, and life, the prosperity of the country is the expansion of its export trade far beyond its present bounds, or those that seem to be such. With one other remark, he would already too extended paper to a close. That for such expansion the fullest and trade is absolutely essential, and hence, to attempt to fetter it with the shackles of duty, or to crush it under the dead weight of tax, would be fatal to the continuance of which, under present conditions, our nation depends.

#### DISCUSSION.

Mr. Hill said he should have liked to have heard of a criterion of value. His experience taught him to put down at the Custom-house were the cost, or mercantile price. He would not say that the import values were inclusive of the cost of the exports were not. He remembered payments of rails to the American markets, were realised, including an *ad valorem* duty, of the price obtained by the English merchant. He did not agree that the large exports of rails to America had been principally paid for in cereals, for instance, he believed they were paid for in iron and other securities. These were to be borne in mind in determining our trade with America. The late activity in this country was attributable to the facts that the price was high and that iron-masters were so desirous of their trade, that they took securities, which, in fact, they would not look at. A very important question, which had not been dealt with, was the duty. There were two giant forces, capital and labour, and if they opposed each other the danger was as the collision between two steamships or trains, yet sufficient attention was not being paid to good relations between these two was the dignity inherent in labour sufficient.

Mr. Walford was glad to find Mr. Bourne, more hopeful than he had been in the past. He had been accustomed to think that if trade again revive, but become worse, Mr. Bourne had been one of the greatest men alive, because he predicted it, but now he feared his fate would be that of Goodwin the astrologer, who predicting of London, but he was so much ridiculing done so, that he died having made the prediction a few weeks before the great fire occurred. (Hill) thought there were decided indications of a revival in trade, but he was not at all sure that the sun-spot theory had not misled a great many who were quite true that, looking at the history of the last century and a-half, there were records of expansion and depression, and the latter always accompanied by predictions such as made. About 1819, the agricultural interest was to be as much depressed as it was now, and it would never recover, but while it did not seem disposed to think that it was in a worse state than then. There was no doubt that America was rival of Europe with regard to agriculture, and it must be so. It would be a bad thing, if our harvests were more productive. In detail, the general question was this—

was it possible, with the vast ramifications of trade, to bring together in one focus all the circumstances which went to make up the greatness of a nation? He thought not. With all the skill and knowledge that even Mr. Bourne could bring to bear on the question, he did not think it was possible to truly forecast the future. And it was well it was so, or speculation would be more rife even than it was at the present. When he saw these great periods of expansion, when the exports approached or exceeded the imports, he did not consider they were the periods of greatest prosperity, but rather the immediate precursors of panics, when the fruit of the speculation of the past was becoming ripe. He hoped, therefore, that, taking a lesson by the past, whatever trade was doing now would be done with safety, and then, if individual or even national profits were smaller, the progress made would be more secure. They would then have an honourable trade, and one which was good for all concerned in it. The thing required, in his mind, was steady progress, and he was quite sure that the discussion of these questions by Mr. Bourne, the Chairman, and others had done good. The problem had been considered all over the world, and though some of the colonies were taking a course with regard to protection which they at home might think wrong, still there were two sides to every question, and the colonies which exported so much raw produce might be justified in taking a course which, to us in England, who imported so much, might seem wrong. No man could safely predict the future in these matters, for he must bow to the force of events.

Mr. Christian Mast thought there was a contradiction in the paper between theory and practice. The practice, as carried out in the figures, was excellent, but the theory at the beginning seemed to be that of cycles, which was not trustworthy. All the circumstances of trade must have causes, and in his opinion the causes were terrestrial only, and had nothing to do with the sun. If Europe was prosperous, it must result either from good harvests, or from the state of affairs and society. He thought periods of prosperity could always be traced to public tranquillity, and bad periods to a disturbed state, social or political. Nothing appeared to him plainer than that in 1871 England was prosperous because France and Germany were depressed, and so in other periods.

Capt. Bedford Pim, R.N., said he must join issue with Mr. Bourne as to the last part of his paper, wherein he deprecated reciprocity and protection. If any one looked around, at the results of free trade, he must feel unbounded astonishment that any one had been wild enough to follow such a Will-o'-the-Wisp. There was not a nation on the face of the earth which had followed Great Britain in this respect, and they could hardly suppose they were the only people in the world who knew what was beneficial. Take the United States. In 1869, they owed £551,000,000; but, in ten years, they had paid off no less than 128 millions sterling, and were now progressing by leaps and bounds, whilst England had only paid off 10 millions of debt since the Queen's Accession. Free trade was to have given cheap food, but Mr. Bourne had admitted that provisions were dearer all round than they used to be. He would at once put a duty of 6s. a quarter on corn, which would produce five millions of revenue, and would only increase the price of bread 2d. on 14 quarters, while it would enable the English farmer to live. Mr. Read told him that it was impossible to grow corn in England under 40s. a quarter, whilst the Americans could lay it down here at 30s.; so that a 5s. duty would equalise matters. Again, in his own profession, it was most important that we should have grain brought in our own ships, but, owing to the repeal of the navigation laws, 80 per cent. of our seamen were foreigners. He was not going to run down foreigners, and the Russian Finns made splendid sailors, but suppose there were a war with Russia,

they would not bring grain cargoes to England. Corn would, in such a case, no doubt, be made contraband of war. A Bill had just been declared urgent in the French Senate for giving bounties to French shipping, and no doubt it would very soon become law. What was England going to do then? Her sugar industry had already been ruined, and 20,000 men thrown out of work by the French bounty system. Steam and telegraphs came into being soon after the free trade system, and soon after came the gold discoveries in Australia and California, and these things caused an expansion of trade, but that was a very different thing from extension. In conclusion, he expressed his opinion that there was never a more complete piece of humbug than free trade.

Mr. B. Francis Cobb said there could be no doubt of the value of the paper, whatever criticisms might be made upon it. He himself should be inclined to criticize some portions of it, as, for instance, where the author said that when a thing was once imported into this country it did not alter its value the more it was manipulated, but if that manipulation consisted of labour expended upon it, and was then re-exported, there was certainly a gain to that country. There was no doubt a great deal to be said on the question of freight, as bearing on the value of exports and imports. The value of money as an importing power was less than it was, and the same quantity of money did more work now than formerly, owing to telegraphic communications. If he wanted to import seeds from India, he had only to give security to an English bank, and he could telegraph out a credit to his agent in India, who could purchase what he required at once, so that an immense amount of the capital which was formerly required to carry out such operations was saved. By this means a much smaller per-centage of profit would repay the merchant, because much less capital was required than in days gone by. All this made it more difficult to forecast the state of trade for the future. When a want arose it was immediately supplied, and there was not the same opportunity for speculation. With regard to Captain Pim's remarks about the colonies and free trade, he would recommend him to compare New South Wales and Victoria. The former, which was a free trade colony, was fast outstripping Melbourne, which was saddled with high protective duties. With regard to foreign sailors, though he had not the statistics at hand, he was convinced there were as many Englishmen under the British flag as there were 30 or 40 years ago; there were certainly as many British subjects.

Mr. Liggins said Mr. Bourne deserved their thanks for the able and exhaustive paper he had prepared, but he was surprised at the conclusion arrived at, to which Captain Pim had already referred. The author had given figures which he considered most disastrous for the future of English trade, and he had stated most truly that the growth of imports, unaccompanied by a corresponding increase of export, could not be considered as evidence of increasing wealth. He (Mr. Liggins) read in the *Times* that morning that one of the largest steamers belonging to the Steam Navigation Company, the *Libra*, had been in collision in the river, and she was going to Hamburg in ballast to fetch a full cargo of manufactured goods for this country, and he did not see how that could be a transaction for the benefit of England. He had always understood that they lived by what they sold, not by what they bought. He was a West Indian proprietor, ruined by free trade, which he could not too strongly denounce. Another thing he saw in the *Times*, was the loss of an English ship, bound from Demerara to New York, with a cargo consisting of the produce of English colonies, intending to return from the United States with a cargo of manufactured goods. How could that be to the advantage of England? He had in his hand a West Indian newspaper, in which three out of four of the advertisements were from New York

traders. One third of the crop of Antigua went each year to New York. All those islands were sending their sugar to America to be manufactured, and only came to England which was manufactured by the merchants. He was a shipowner, and the part of the sailors he had to employ were French, and he feared that, in case of a war, we should have difficulty in getting men to man our ships and fight our battles. Mr. Bourne's figures were black and white, but he did not think they were as black as the reality. He could corroborate what Captain Pim had said about French shipping, for only lately a French ship had told him that France intended to do all the trade of the world, and to drive England out of the market. There was a worse feature even than that, for there was an agitation going on in America to subvert the shipping line, in order to drive the large English steamships out of the line. He held shares in one of the largest ship companies, which last year paid no dividend, and he knew of one Liverpool vessel which lost at one voyage. This could not go on. If England lost her ships, her colonies, and her commerce, she would soon be much worse than any Mr. Bourne given. He did not think it was fair to 1879 and 1880, because accidental circumstances show an improvement in one year. The country ought to be made with 1872. With regard to sugar industry, he considered it a great mistake to take the duty off sugar. It produced five million revenue, and gave the working man an opportunity of contributing something to the revenue of a country which gave him such high wages. Working men beginning to see that a free breakfast table was a take, and meant low wages. The working man should rather make the things they manufacture higher in price, and then they would get good wages. Nine-tenths of them were now beginning to see that free trade brought them low wages. In the Kent Town-hall £10,000 worth of Belgian iron was sold, and in the Albert-hall, £70,000 worth, and certainly no benefit to the working classes. They showed they were importing more than they exporting, which must mean ruin in the end.

Mr. Pfundes said, when he was in Japan and he had many opportunities of mixing with the natives and looking at trade questions from the native point of view, and the result of his experience was that the most crying need for successful English trade was more competent agents. For want of them, important work was committed to natives, who, if they used the information they obtained for their own ends. Again, the old-fashioned system of English trade was on far too expensive a scale—a greater part of the time of the agents being spent at the club, at full-dress dinners—the consequences being that the charges were out of all proportion to those incurred by the more thrifty of our continental competitors. In the consular service, young men, admirably in many respects, were sent out, but they were not allowed to engage in trade; they knew nothing of the matter, and could not compete with the representatives of other countries. He could not agree with the criticism of a previous speaker, that Mr. Bourne's figures were not trustworthy.

Mr. Hill asked if Mr. Bourne could give an estimate of the present purchasing power of money, as compared with 1826 or 1828.

The Chairman said that though the discussion had been interesting, it had to a certain extent been cursive, one or two sentences in the paper had led into a discussion of the principles of free trade. He should not go into that question at any length, because, notwithstanding what had been said, he should assume that the majority of those present, and at any rate the Society, as a whole, were in favour of free trade. He must remark, however, that

ing all the predictions which had been made as to the results which would follow our free trade system, and which had been very long in coming, and he was resolved to maintain that, at the present time, there was no country in the world, not even excepting the United States, more prosperous than Great Britain, or so much a large mass of people had employment at wages, and had so fair an opportunity of enjoying a health and comfort. With regard to foreign imitations of our free trade policy, he might remark that if they were at all logical, they would follow their protective system much farther; the United States, for instance, should not only have a tariff against foreign countries, but New York should have a tariff against Massachusetts, and so on, so as to derive the utmost benefit from the protective policy. There was the smallest foundation for the statement that men had been thrown out of employment in the iron industry; at the present moment there was more iron refined in the United Kingdom than at any period, and if there were fewer people employed, it was due to improvements in the mode of manufacture. There was no foundation for the statement, it would be found, that the less employment was due to the bounties of the foreign Governments, and this question had been faced by those who had been promoting the repeal of the sugar bounties. Coming to the iron trade, he should like to say that, so far as he could judge, it was a little less gloomy in its state than some former papers by Mr. Bourne, still, on the other hand, there was a tendency to too much gloom, and the facts and in the anticipations put forward. In speaking of the iron trade, he threw out the suggestion that the home consumption had

Now he had occasion, some time ago, to go a little more narrowly into the figures, and was satisfied that from October to the end of December, there was an increase of something like 25 per cent. in the home consumption of iron; for although the iron imports had decreased, the increased stock, added with the same period of last year, was very large, and the immense increase in the production had been nearly all absorbed in various manufactures at home. With regard to the cotton trade, he said that stocks were supposed to be accumulating in the East; but, as far as he could discover from the circulars, those stocks were extremely well adapted to consumption. Another fact, from which he did not draw a gloomy conclusion, was, that last year there was no increase of exports to Australia; but the exports were very well, that two or three years ago our exports to foreign countries were not so large as those to the colonies, and partly to the United States, were increasing. It was hardly fair to say every year to show an increase to the world; there must be ups and downs, and there might be special circumstances which might be export to Australia in one particular year; but it might be well satisfied with the increase which had taken place in our Australian trade during the last few years. With regard to the main question, he took exception to the apparently exaggerated imputation attached to foreign trade; and he did not agree with the statement of home trade what one man gained necessarily be at the expense of another; as a rule, the change which took place was to the mutual benefit of both parties. He believed the home trade, and the foreign, was really the important matter. He also seemed to found his anticipations for the future on the assumption that trade revived more than it went back, and that when it began to rise, the highest point was soon reached, and that it gave us an instance the period of the American war. Now he took exception to that. The revival of trade there referred to, did not come after the war, but long before, and was owing to the fact when the war broke out. He remembered

noticing the revival of trade which took place in Lancashire in the autumn of 1869, and 1870 was really a very prosperous year, so much so, that when the war broke out, it caught the Stock Exchange in the full swing of speculation, and the result was a panic, unprecedented in the memory of the present generation. The proper year, therefore, to compare with 1880, was 1870. It was very likely that the present revival had been unusually rapid; but whether it would soon attain its maximum, and give place to a reaction, was a question which he agreed with Mr. Walford it would not be wise to discuss with too much obstinacy on one side or the other. They could never be sure, with all the pains they might take to form an absolutely correct anticipation of what would happen. According to past experience, there was reasonable ground for supposing that business would go on improving, but it would be foolish to attempt to predict with certainty. Some of the political causes for not expecting a very favourable result he thought Mr. Bourne had dwelt too much upon, for instance, the political troubles in India and at the Cape. The amount of money involved, though large, was very small when compared with the magnitude of our commerce. The succession of bad harvests had probably had much more influence. He would conclude by expressing his entire approval of Mr. Bourne's remarks with respect to the state of speculation at the present time, especially in securities. There could be no doubt that the advance, which was the cause of so much satisfaction to many people, was only a change in the nominal expression of wealth, and represented no real increase. People were really no richer than they were before, and one of the dangers of the future was the length to which the speculator might go.

Mr. Bourne, in reply, regretted that the main purport of his paper had not received more consideration. The point for consideration was what lessons for the future could be drawn from the past, so that their operations might be guided accordingly; and he must remind the meeting that, having previously written several papers, which would be found collected in a volume in the Library, he had now omitted many points with which he had before dealt. For instance, he had fully considered the question raised by Mr. Hill with regard to the influence of freight on the value of exports and imports; and on the present occasion, his object being to compare one period with another, the figures being on the same basis throughout, their absolute accuracy was not of importance. The purchasing power of money was much too large a question to say anything useful upon at that late hour. His object had not been to give a gloomy view, but to put the facts fairly before the public, and he must congratulate himself that he had been the means of directing attention to the real state of the case, which had not been without some advantage in the influence it had had on the conduct pursued. He looked with a great deal of suspicion on the progress of our trade, and a great deal of the political economy of the present day, but, as for looking with any depression on the condition of England, he did not. He only wished to point out the sources from which she might arrive at a grandeur and wealth far beyond what she had ever achieved. The two great requisites were the study of economy and an attempt to follow the American example by taking in our outlying territories, moving our population east, west, north, and south, and embracing in the sphere of our cultivation those portions of our dominion which would furnish prosperous and comfortable homes to those who were now in poverty and destitution. He had no pretensions to prophecy; he only reasoned on the past, to show why it justified an anticipation of the future, and wherein present circumstances differed from past, so that we might learn how best to meet that which was coming. This was the same as was now done with regard to the weather; we obtained information from America of what was passing there at the moment, and from that

drew conclusions as to the weather we might shortly expect in Europe. If he had dwelt more upon the gloomy side, it was because it was more important to guard against possible evils, than to look out for coming prosperity. He had no belief in cycles or the sun-spot theory; but there was the fact, that alternate periods of the inflation and depression had hitherto occurred pretty regularly, and this led many people to suppose that the same thing must happen again, and so speculate largely on the first indications of a revival; and it was this he wished to guard against, as it led to artificial inflation and a corresponding depression which need not otherwise occur. When he said that the rise was more rapid than the fall, he alluded to this influence. He was glad the Chairman agreed with him that the speculation at present going on was excessive; he feared it would produce an inflation, for which they would suffer severely afterwards. He could not now discuss the question of free trade, but it must be remembered that the circumstances of England differed so greatly from other countries, that we must needs follow a different policy. Here we had a population which we could not feed from our own stores; while America had a population which could not consume half of what she raised. As to the statement that we wanted an extension of trade, rather than an expansion, that was the argument he had constantly enforced; we wanted to enlarge our sphere of operations. With regard to the periods he had selected, 1872 was the period of highest elevation, and 1879 that of the lowest depression, and, therefore, he thought they were fairly selected. Mr. Liggins regretted that so much of our colonial sugar went to New York, but for his part he thought if we could get good customers in any part of the world it was matter for congratulation. The question of exports and imports he had treated fully elsewhere. He was surprised at the Chairman thinking he had taken too gloomy a view, but as he had already said, his only object had been to guard against possible evils, on the principle that forewarned was forearmed. Still, he could not take the cheerful view which was adopted by many writers at present. All the writings of the day seemed in favour of speculation, and that led to the inflation, which caused a subsequent depression. With regard to the home consumption of iron, he had taken the figures from trade circulars. The assumed make and the annual export did not leave a sufficient balance to account for the enormous home consumption which was generally assumed.

The Chairman said the exports were very large in the early part of the year, and the increased consumption at home was mainly in the last three months.

Mr. Bourne said he had only quoted the absolute figures. At any rate, he thought the exports of iron were likely to fall off. With regard to the troubles in India and the Cape, it was not altogether the amount of expenditure to which he referred, but to the fact that we had been killing our customers rather than encouraging them. The question of the morality of the proceedings was one which he would not attempt to enter upon. He was glad that Mr. Giffen endorsed what he said about speculation, for it was that they had most to fear at present. The belief that the trade must necessarily advance by leaps and bounds, was likely to produce a vast amount of that evil, and the growth of the speculative spirit in the present day had raised up and maintained a large portion of the community, who, instead of being producers, were living on the labour of others; and this was one of the most disastrous things connected with trade which could happen. No language could be too strong to condemn the fact of our having in our midst such a large number of non-producers, who did nothing whatever to add to the wealth of the country, but simply by *passing goods from hand to hand*, and stimulating pur-

chases to an undue extent, absorbed from the labourers a large proportion of their gains, one of the most fatal elements in the present condition of our trading society, and the one most to guard against.

Votes of thanks to Mr. Bourne and the concluded the proceedings.

## CORRESPONDENCE.

### SIGNALLING BY MEANS OF SOUND

In reference to Mr. H. P. Babbage's letter appeared in the last number of the *Journal*, I to say that the proposal of the late Mr. Charles received the most careful consideration in 1871 experience of the Elder Brethren of the Trinity as practical seamen, was quite opposed to its or indeed practicability, for the distinguishing lighthouses.

As regards its application to sound signals Mr. Babbage does not appear to have any adequate conception of the requirements of the marine ineffectiveness of such a system for the purpose the difficulties, expense, and risk to navigation would be involved by its introduction in place now in existence.

All practical seamen condemn any system necessitates exceedingly accurate and strained concentration. When the mariner's mind is full of anxiety, labouring under the influence of a strong wind or sea, he does not then desire to have to count the flashes, the occultations or sound blasts, to assure himself of his position. Especially time would the numerical system be liable to any of the signals may be temporarily obscured, by the rolling of the vessel, or by a poor steam, the master reads 323 for 333 and in course on the supposition that the light is No would be the consequence of such a mistake.

The late Mr. Charles Babbage, as a mathematician, was naturally very familiar with the language of figures, and, probably, Mr. H. inherits something of his father's proclivity for gentlemen, and, indeed, to most landmen a chart, it would appear that the simplest way would be to number every lighthouse and every sound and cause it to indicate that number. Nothing could apparently be easier or more simple. But they seem to forget altogether that the signals themselves would not be exhibited to the mariner, he would see only flashes, or occultations, or he would have to interpret the signals in the times when, as I have before indicated, all would be required for the management of the signals themselves, and when he would be especially liable to a mistake.

It is almost time that this controversy came to an end, so often has it been shown that the arguments of advocates of refined distinctions are fallacious. Really wanted is extreme simplicity, regard to the mariner's point of view, not from the point of view of the mathematician, electrician, or any other. Each signal must proclaim to the mariner, in time as possible, its own character, so that he may once recognise it. That is the object aimed at by lighthouse authorities at the present time, a simple, efficient, and adapted to the requirements of the service is acknowledged by all practical seamen with our coast signals, and is only called in question by those whose experience has not made them aware of the practical necessities of the case.

E. PRIOR

London, 26th January, 1881.

# MEANS FOR PREVENTING LONDON SMOKE.

week's *Journal* (28th January), in Mr. Moncrieff on the above-named subject, he refers to the Arsenal Gas Works as having practically his scheme of "using fuel, from which a certain portion of gas only has been extracted."

was not present at the meeting, and unaware Mr. Moncrieff intended referring to the works in charge, I beg to be allowed to refute the view in his paper, in so far as they relate to the Arsenal, or any other of the Government gas

works ago, during an exceptionally busy period, the Government departments were working all the time unable to meet the greatly increased demand for gas, and was therefore compelled, at that time, to occasionally charge, to work a few ovens on a six-hour charge, so as to obtain a larger quantity of gas in the 24 hours than could possibly be obtained by means of the ordinary six-hour charge. It is quite a mistake to suppose, as might be inferred from the above, that I only obtained 3,333 cubic feet per ton of coke, or that the short extraction was only owing to the coke from the short time being greatly superior to ordinary gas coke, but that, in assisting the operation, seeing that in the Arsenal with the four-hour charges a volatile candle was produced, the coke from which contained very little volatile matter, and consequently was not used as fuel for the Arsenal; and so far from "superiority of the charges being proved," as stated, the plan was a very expensive and uneconomical, and resorted to in order to meet a few exceptional cases; and it is not likely to be adopted again, the works have recently been enlarged to meet the demand that I shall be able at all times in future, to produce six-hour charges, and taking all the gas from the coal, to keep a sufficient stock on hand to meet the requirements of the departments, under any circumstances that are ever likely to arise.

Therefore, on behalf of all the Government departments under my superintendence, I disclaim any right to give credit to having adopted Mr. Moncrieff's scheme of reducing coke containing a large quantity of gas, as the War Department would be far from doing if, instead of producing, as at present, 30 and 10,000 cubic feet of 16-candle gas per ton of coal carbonised, I were to give them about this quantity, and to offer a greatly increased quantity of tar in lieu thereof, with coke from a small proportion of the gas had been extracted.

J. A. C. HAY.

at Woolwich,  
January, 1881.

Mr. Wallace, who manages the Royal Arsenal under my superintendence, assures me that he will furnish the statements contained in Mr. Moncrieff's paper in regard to these works, and that they were made without his knowledge or consent.

J. A. C. H.

On reading last Wednesday, by Mr. W. D. Moncrieff, on "Suggestions for Preventing London Smoke, and making it commercially available," that if the 4,000,000 tons of coal used in London for heating purposes were all put into the gas companies (in addition to the coals now used by the gas companies), and manipulated, as he says, London would be a "smokeless city," and saving of some two millions sterling effected. Mr. Moncrieff asserts that if the gas companies used one-third the quantity of gas they now use of coal, the coke, or "smokeless fuel," would have a heating capacity of fully 20 per cent.

greater than common coal, and 10 per cent. greater than coke; but we are not favoured with any statistics to prove this, against which I will take the lecturer's own figures—the paper assumes a commercial aspect—how is it then that if coke has a heating capacity of 10 per cent. in excess of coal, its commercial value is 25 per cent. less—coke being valued at 12s. per ton, against 16s.? I venture to think this question should be treated in a practical manner, and taking Mr. Scott-Moncrieff's figures, I submit the following, from a gas maker's point of view:—

## Present Net Cost of Coals for making London Gas.

2,000,000 tons of coal, at 16s. ....	£1,600,000
Labour thereon, at 2s. ....	200,000
	<b>£1,800,000</b>

Less tar and ammonia, at 3s. 9d. per ton of coals .....	£375,000
1,000,000 tons of coke, at 12s. ..	600,000
	<b>975,000</b>

Nett cost of coal under present *modus operandi* £825,000

Mr. Scott-Moncrieff proposes that, instead of using two million tons of coal, the gas companies should use six million tons.

6,000,000 tons of coal, at 16s. ....	£4,800,000
Labour thereon, at 2s. ....	600,000
	<b>£5,400,000</b>

Tar and ammonia is valued at double present sales, or 2s. 6d. per ton of coals .....	£750,000
--	----------

And if no more coke were used for carbonising "in the retorts, on an extraction of less than three hours, instead of six hours, at present prevailing," there would be 2,000,000 tons of fuel for sale, which I cannot value at more than 10s. per ton ....	£1,500,000
	<b>2,225,000</b>

Nett cost of coal under proposed new system £3,175,000

I may add, in passing, that Mr. Scott-Moncrieff calculates 17 cwt. of coke made per ton of coals under the proposed system, against 13 cwt. as at present, with a per-centage used for fuel only, 19½ against 23 at present. I submit that not more than, if so much, as 10 cwt. of coke per ton of coals would be left for sale by the more frequent charging of the retorts.

Mr. Scott-Moncrieff assumes that, by making only one-third of the quantity of gas now made per ton of coal, the illuminating power would be raised from 16 to 24 candles, i.e., 50 per cent., and that the gas would be worth 50 per cent. more money, or 5s. 3d. per 1,000, instead of 3s. 6d., an increase of 1s. 9d. per 1,000, which the consumers would be called on to pay.

I don't think this requires more than a passing notice. A gas consumer, with two burners in his room or shop, can use a third if he chooses to increase his light. Why does he content himself with two? Simply because he does not want to pay for the third or extra light.

We have not been favoured with facts from actual workings, and I think the members of the Society of Arts would like to be informed.

1st. Whether a 16s. coal, producing 10,000 cubic feet of 16-candle gas, will produce at the consumer's burner 3,333 cubic feet of 24-candle gas; 2nd, where and when has the test been made, proving that the coke of 3,333 gas "has a heating capacity of fully 20 per cent. greater" than the coal from which the gas has been extracted.

At the Beckton Gas Works, a year or two ago, there were literally mountains of coke which was unsaleable in London, and had always to be given away in shipment to the Continent. The severity of the last two winters has kept coke stocks pretty clear. Is it to be assumed that the "smokeless fuel" proposed to be made will command a better sale than the ordinary gas coke? I think it may be taken for granted that such fuel exposed for a few days during the recent weather, would have become a heap of rubbish on removal from the gas works.

According to my figures, London, instead of having four million tons of coal and one million tons of coke for fuel, would have to be content with three million tons of "smokeless fuel," and the gas companies saddled with an increase of £2,350,000 in the cost of producing their gas.

R. H. JONES.

Sydenham, 31st January, 1881.

### KITCHEN BOILER EXPLOSIONS.

Having regard to the number of kitchen boiler explosions occurring at the present time, many of them attended with fatal consequences, it might perhaps be of service if you could find room for the following in your columns.

LAVINGTON E. FLETCHER.

#### INSTRUCTIONS FOR A PLACARD.

On the recurrence of frost, it might be well to have placards printed in large clear type and posted in prominent positions in the public thoroughfares or other suitable places, explaining to the public the best means of preventing kitchen and circulating boiler explosions.

#### TEXT FOR PLACARD.

##### *Manchester Steam Users' Association on Kitchen and Circulating Boiler Explosions.*

Kitchen boiler explosions are due to an accumulation of pressure in the boiler, in consequence of the outlets being stopped up while the fire is burning. These explosions occur during the frost through the choking up of the pipes with ice. Sometimes stop-taps are placed in the circulating pipes, and should these taps be shut, or should the circulating pipes become choked with sediment, or stopped up from any other cause, the pressure would then be bottled up, and an explosion might result at any time, whether summer or winter.

To prevent this, every boiler should be fitted with a small reliable safety valve, whether the boiler be of copper or cast-iron, and whether it be fitted with a copper cylinder or not. A safety valve of dead weight construction is recommended as the most simple. In the event of the outlets becoming choked, it would relieve any undue pressure and prevent an accumulation, while at the same time it would emit a slight hissing noise, which would tell those in the kitchen that something was wrong.

In the meantime, until a safety valve can be fixed, open the hot-water tap in the bath-room, and any other hot-water taps connected with the boiler. If the water cannot be drawn freely from these taps, do not light the fire, and if the fire be already lighted, put it out at once. If the water flows freely, the fire may then be lighted, but this must be done with caution, and the taps just described frequently opened to see that the flow continues, and that the water gradually heats. If the flow does not continue, or if the water does not heat, the supply of water to the boiler must be running short, or something must be wrong with the circulation, and the fire must be drawn. Also the cold-water cistern as well as the ball-tap should be examined, and the cold-water taps in the bath-room, and elsewhere, opened to see that the water supply is free, otherwise the boiler may run dry. When the fire is once lighted, and the circulation proved to be free, the fire should be kept burning by night as well as by day as long as the frost lasts, otherwise the frost may get the mastery during

the night, choke the pipes with ice, stop bottle up the pressure, and thus lead to the boiler. But the only true safeguard safety valve, and the sooner that is fixed the better.

LAVINGTON E. FLETCHER.

9, Mount-street, Albert-square, Manchester, January, 1881.

P.S.—The Manchester Steam Users' nothing whatever to do with the manuf: the dead weight safety valve recommend be of convenience to the public to state in accordance with the association's dra obtained for 10s. 6d. at Messrs. Isaac St Cathedral-yard, Manchester.

### NOTES ON BOOKS

**Report upon certain Museums for Technical and Art; also upon Scientific, Practical, Technical Instruction, and System Classes in Great Britain and on the Continent.** By Archibald Liversidge.

In 1878, Professor Liversidge, of the Sydney, was desired by the Colonial Society of South Wales, and also by the Chancery of Sydney, to collect information technological and industrial museum schools, &c., of Europe, for the guidance of Trustees appointed to found a Technical Museum at Sydney. The Liversidge's investigations are contained in London, Edinburgh, Oxford, and Conservatoire des Arts et Metiers, Paris, Italian Industrial Museum, Turin. It is devoted to the various institutions of technical instruction is given. Three are situated in Great Britain and in Austria, four in Belgium, forty-one in Germany, three in Holland, four in Russia, two in Sweden, one (the Polytechnic) in Switzerland, and one (the Institute of Technology, Boston) in the United States. The appendix contains a list of public technical education, &c., and a copy of Stanley's circular upon Technical Education to her Majesty's representatives: their replies (1868).

**Trade, Population, and Food: a series of Economic Statistics.** By Stephen B. George Bell and Sons, 1880.)

In this volume the author has arranged papers on cognate subjects, published at the proceedings of societies, so as to form a whole. Under the first head, the problems dealt with, and special attention is drawn to the growing preponderance of imports. The second division relates to the social aspects of trade depression, specially devoted to the finance of nations in which the practicability of the measure proposed for the prevention of pauperism from a financial point of view. The third is devoted to the subject of food supply, in which "Wine," and "Drinking and Debauchery" are considered. The result of Mr. Bourne's conclusions is:—"The needed explanation of the phenomenon manifested in the growing exports beyond that of our exports is a state of affairs with a prosperous state of trade and man-

have to feed, and the food required to feed increased beyond the powers of our own soil; and that other nations have been growing in wealth, and manufacturing power, and the capacity for supplying their own wants, increasing, but rather decreasing, their demands on products of our labour by which our ability to feed from them is largely maintained. Our food has been multiplied by continuous seasons of produce from our own soil, whilst agricultural operations have been progressively advancing

**Manual of Modern Geography.** By John Murray, M.A. (London, John Murray, 1880.)

This is compiled on the same plan as the "School Geography" of the same author, and is intended for junior students. It is not merely an abridgment of the larger work, but contains matters which were considered superfluous in the introduction. It contains some general astronomical or mathematical, physical, and geographical notes.

## GENERAL NOTES.

**ber.—**Information concerning the plant *Caesalpinia* is contained in the report on the plant by Dr. H. Trimen, of Ceylon. The plant is said to grow in a dry, rough soil, and a moderate atmosphere, while the Para and West India require a rich alluvial soil, and a constantly moist atmosphere. *Caesalpinia* plants have been found in Ceylon, Calcutta, and Madras, but the climate is too hot for them. It is suggested that the plant should be formed on exhausted coffee land. The plant is about thirty feet or more in height, and forms a dense crown. It attains a diameter of four or five inches about two years, when it may be tapped.

**Sanitation.**—Dr. Richardson, F.R.S., will give a series of nine lectures on "Domestic Sanitation or Hygiene," before the Ladies' Sanitary Association, of the Society of Arts, on the Saturdays, from 10th to April 9th. The subjects dealt with in the lectures are: (1) food and digestion, (2) the circulation of the blood, and the means of purifying the organs of circulation in a healthy state, (3) the allied subject of ventilation. A first prize of five guineas and a second prize of five guineas, offered by Dr. Richardson, Esq., C.B., will be awarded to the two who have most distinguished themselves by a knowledge of the subjects taught in the lectures. Dr. Richardson will also give first and second-class certificates of merit and proficiency to students who wish to compete.

**Technical Institute.**—The programme for the City Technical Science Classes has been issued. Professor Armstrong, Ph.D., F.R.S., and Professor J. L. C.E., will continue the courses of instruction in chemistry and physics as applied to the arts and manufactures, at the Copper-street Schools, Finsbury, in connection with the Middle Class School Corporation, and the erection of the City and Guilds Technical Institute. In the evening Chemistry Classes, Dr. Richardson will lecture on "Organic Chemistry, with special reference to its Industrial Applications." The chemistry of the products, their uses, and the production of dyeing from them will be very fully considered. The brewing, spirit distilling, and vinegar-making will form the subject of the lectures after Easter. Dr. Richardson will deliver a course of lectures for junior students to the practice and theory of chemistry, on Saturdays, from 12 to 1 p.m., commencing January 27th. The object of these lectures is to afford such preliminary instruction as may be necessary for those who may desire later on to take a course of applied chemistry, but the attention will be specially directed to the technical side of the subject. He will also give a course of lectures

on "Coal Gas, and its uses as an Illuminating and Heating Agent." A junior introductory course will also be given; and there will also be laboratory classes and a Photographic Chemistry Class. In the Physical Class, Professor Ayrton will give courses of lectures on "Electrical Instrument Making," "Electric Light," "Motor Machinery, with special reference to Electric Lighting," and the "Electric Transmission of Power." In this department also there will be laboratory and junior classes.

## MEETINGS OF THE SOCIETY.

### ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

FEBRUARY 9.—"The Present Condition of the Art of Wood-carving in England." By J. HUNGERFORD POLLEN. Sir PHILIP CUNLIFFE-OWEN, C.B., K.C.M.G. C.I.E., will preside.

FEBRUARY 16.—"The Participation of Labour in the Profits of Enterprise." By SEDLEY TAYLOR, M.A., late Fellow of Trinity College, Cambridge.

FEBRUARY 23.—"The Manufacture of Aerated Waters." By T. P. BRUCE WARREN.

MARCH 2.—"On Lighthouses Characteristics." By Sir WILLIAM THOMSON, LL.D., F.R.S.

MARCH 9.—"Improvements in the Treatment of Esparto for the Manufacture of Paper." By WILLIAM ARNOT, F.C.S.

MARCH 16.—"Buying and Selling; its Nature and its Tools." By Prof. BONAMY PRICE, M.A. Lord ALFRED S. CHURCHILL will preside.

MARCH 23.—"The Increasing Number of Deaths from Explosions, with an Examination of the Causes." By CORNELIUS WALFORD.

MARCH 30.—"Recent Advances in Electric Lighting." By W. H. PREECE, Pres. Soc. Tel. Eng.

APRIL 6.—"The Manufacture of Glass for Decorative Purposes." By H. J. POWELL (Whitefriars Glass Works).

### FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

FEBRUARY 22.—"The Languages of South Africa." By ROBERT N. CUST.

MARCH 15.—"The Loo Choo Islands." By Consul JOHN A. GUBBINS.

APRIL 5.—"Trade Relations between Great Britain and her Dependencies." By WILLIAM WESTGARTH.

### APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

FEBRUARY 24.—"Deep Sea Investigation, and the Apparatus used in it." By J. G. BUCHANAN, F.R.S.E., F.C.S. Captain Sir GEORGE S. NARR, R.N., K.C.B., F.R.S., will preside.

MARCH 24.—"The Future Development of Electrical Appliances." By Prof. JOHN PERRY.

The meeting previously announced for April 7 will be held on May 12.

### INDIAN SECTION.

Friday evenings, at eight o'clock:—

FEBRUARY 11.—"Gold in India." By HYDE CLARKE. Sir WILLIAM ROBINSON, K.C.S.I., will preside.

MARCH 4.—"The Results of British Rule in India." By J. M. MACLEAN.

MARCH 25.—"The Tenure and Cultivation of Land in India." By Sir GEORGE CAMPBELL, K.C.S.I., M.P.

MAY 13.—"Burmah." By General Sir ARTHUR PHAYRE, G.C.M.G., K.C.S.I., C.B.

Members are requested to notice that it may be necessary to make alterations in the dates of the above papers.

## CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Second Course will be on "Watchmaking," by EDWARD RIGG, M.A. Three Lectures.

*Syllabus of the Course.*

## LECTURE I.—FEBRUARY 7.

Introduction—Units of Time—Historical Sketch—Description of usual forms of watch—Escapements—Conditions of accurate timekeeping, and arrangements necessary for their maintenance in the higher class of watch.

## LECTURE II.—FEBRUARY 14.

The ordinary watch—Degree of accuracy required in it—Systems of manufacture in this country and abroad—Description of specimens illustrative of the various stages of construction—Comparison of the several systems.

## LECTURE III.—FEBRUARY 21.

Necessity of efforts to promote the art in this country—Need of education, theoretical and practical, in horology—Literature—Great want of uniformity in gauges, screws, &c.—Exhibition of ordinary and complicated watches, and of watchmakers' tools—Conclusion.

The Lectures will be illustrated by Specimens, Models, and Diagrams. The different movements, &c., will be shown enlarged on the screen by means of the Aphenoscope and the Electric Light.

The Third Course will be on "The Scientific Principles involved in Electric Lighting," by Prof. W. G. ADAMS, F.R.S. Four Lectures.

March 7, 14, 21, 28.

The Fourth Course will be on "The Art of Lace-making," by ALAN S. COLE. Three Lectures.

April 25; May 2, 9.

The Fifth Course will be on "Colour Blindness and its Influence upon Various Industries," by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

May 16, 23, 30.

## ADMISSION TO MEETINGS.

Members have the right of attending all the Society's meetings and lectures. Every Member can admit *two* friends to the Ordinary and Sectional Meetings, and *one* friend to the Cantor Lectures. Books of tickets for the purpose have been issued to the Members, but admission can also be obtained on the personal introduction of a Member.

## MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 7TH... **SOCIETY OF ARTS**, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. Edward Rigg, "Watchmaking." (Lecture I.)  
Farmers' Club, Inns of Court Hotel, Holborn, W.C., 4 p.m. Mr. J. Bailey Denton, "The Management of Rivers."  
Royal Institution, Albemarle-street, W., 6 p.m. General Monthly Meeting.  
Society of Engineers, 6, Westminster-chambers, 7½ p.m. Presentation of the premiums awarded during the past Session, by the late President, Mr. Joseph Bernays. Inaugural Address by Mr. Charles Horsley, President.  
Institute of Surveyors, 12, Great George-street, S.W., 8 p.m. Discussion on Mr. Joseph Lucas's paper, "Rural Water Supply, with Special Reference to the Objects of the Public Health (Water) Act, 1878."  
Medical, 11, Chandos-street, W., 8½ p.m.  
Victoria Institute, 7, Adelphi-terrace, W.C., 8 p.m. Dr. E. Kinne, "The Truths of Revelation Confirmed by the Advance of Science."

London Institution, Finsbury-circus, E.C., H. S. Maine, "Succession to Thrones."

TUESDAY, FEB. 8TH... **Royal Institution**, Albemarle-street, W., 8 p.m. Prof. E. A. Schiffer, "The Blood." (Central Chamber of Agriculture (at the H. Society of Arts), 11 a.m.)  
Medical and Chirurgical, 53, Berners-street, W., 8½ p.m.  
Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Mr. C. Colson, "The Dockyard Extension Works (2nd Part)."  
Meyer, "The Plant and Temporary Works Portsmouth Dockyard Extension."  
Photographic, 5A, Pall-mall East, S.W., 8 p.m. General Meeting.  
Anthropological Institute, 4, St. Martin's-street, 8 p.m.  
Royal Horticultural, South Kensington, S.W.

WEDNESDAY, FEB. 9TH... **SOCIETY OF ARTS**, Adelphi, W.C., 8 p.m. Mr. J. Hunger, "The Present Condition of the Art of W in England."  
Graphic, University College, W.C., 8 p.m.  
Microscopical, King's College, W.C., 8 p.m. Meeting for Election of Council and Officers.  
Royal Literary Fund, 10, John-street, Ad 3 p.m.  
Royal Institution, Albemarle-street, W., 8 p.m. Sidney Colvin, "The Amazons." (Lecture)  
Sanitary Institute of Great Britain, 9, Conduit-street, 8 p.m. Mr. W. H. Michael, "The Law in Sanitary Progress."

THURSDAY, FEB. 10TH... **Telegraph Engineers and** 25, Great George-street, S.W., 8 p.m. Mr. Adams, "Earth Currents—Electric Tides."  
Royal, Burlington-house, W., 4½ p.m.  
Antiquaries, Burlington-house, W., 8½ p.m.  
London Institution, Finsbury-circus, E. Prof. Monier Williams, "The Castes in India."  
Royal Institution, Albemarle-street, W., 8 p.m. Francis Hueffer, "The Troubadours." (I. Inventors' Institute, 4, St. Martin's-place, W. Royal Society Club, Willis's-rooms, St. James's, 8 p.m.)  
Mathematical, 22, Albemarle-street, W., 8 p.m. E. B. Elliott, "Some Theorems of Kinetic Sphere." 2. Mr. J. W. L. Glaisher, "Some expressible in the terms of the first compound of Gamma Functions." 3. Herr Schilling, "Mr. McColl's Calculus of Equivalents."

FRIDAY, FEB. 11TH... **SOCIETY OF ARTS**, John-street, W.C., 8½ p.m. (Indian Section.) Mr. F. "Gold in India."  
Royal United Service Institution, Whitehall, Lieut.-Col. C. R. Sherrington, "Army and Navy." Royal Institution, Albemarle-street, 9 p.m. Ball, "The Distance of the Stars."  
Astronomical, Burlington-house, W., 8 p.m. General Meeting.  
Quekett Microscopical Club, University College, 8 p.m.  
Clinical, 53, Berners-street, W., 8½ p.m. Ann Folk Lore Society, 22, Albemarle-street, W., 8 p.m. W. S. Lach-Szyrma, "Folk Lore Traditions Events."

SATURDAY, FEB. 12TH... **Ladies' Sanitary Association** (of the Society of Arts), 5.30 p.m. Dr. B. son, "Domestic Sanitation or Health at Home (Lecture I.)"  
Physical, Science Schools, South Kensington, 1. Annual General Meeting. 2. Special Geology. 3. Dr. O. J. Lodge, "A Hydrostatic Ill Electrical Phenomena, and other Lectures."  
Royal Botanic, Inner-circle, Regent's-park, N. Royal Institution, Albemarle-street, W., 8 p.m. Sidney Colvin, "The Amazons." (Lecture)

ERRATA.—Page 161, col. 1, l. 51, *for* read sulphides; p. 161, col. 1, last line, *for* tons, *r* p. 161, col. 2, l. 9, *for* Anderson, Longmaid, A. Rhodin, *read* Henderson, Longmaid, Augustin, or Rhodia; p. 161, col. 2, l. 10 *from* bottom, *for* metals; p. 162, col. 1, l. 36, *for* or about 46 to 6 *read* only about 46 to 48 per cent.; p. 162, col. 1, 26 per cent., *read* 96 per cent.; p. 162, col. 1, bottom, *for* miner, *read* mine; p. 162, col. 2, l. 18 *body engaged, read* everybody could not engage.

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,473. Vol. XXIX.

RIDAY, FEBRUARY 11, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## NOTICES TO INSTITUTIONS.—EXAMINATIONS.

Attention of Secretaries of Institutions in  
with the Society, is directed to the Pro-  
of Examination sent to each Institution  
a week's *Journal*, especially to paragraphs

Institutions desirous of using the ele-  
papers issued by the Society, are reminded  
lication for them should be made at once.  
e 7 of the Programme.

## CANTOR LECTURES.

First lecture of the second course was  
d on Monday, 7th inst., by Edward Rigg,  
a "Watchmaking." The lecturer gave a  
sketch of the subject, and described the  
rms of watch escapements, conditions of  
timekeeping, and arrangements necessary  
maintenance in the higher class of watch.  
ectures will be published in the *Journal*  
the summer vacation.

## TELEPHONE EXCHANGE.

Offices of the Society of Arts have lately been  
ed with the Telephone Exchange, the head  
of which are situated in Coleman-street.  
ny member of the Society, whose place of  
is also connected with the Exchange,  
is communicate with the Society. The  
s offices are connected, in the first instance,  
e company's Exchange in Chancery-lane,  
can be put into communication with any  
station from which wires radiate to the  
places using the Exchange system. The  
re also connected by a private wire to the  
s printers in Fleet-street, the company's  
e being now used instead of the Wheat-

stone A. B. C. instrument, which had previously  
been employed on a Post-office wire for the same  
purpose.

## HOUSE SANITATION.

The Council offer the following Medals for the  
best Sanitary Arrangements in Houses built in  
the Metropolis, the plans of such arrangements to  
be exhibited in the Society's Rooms, Adelphi, in  
June, 1881, and to be sent in on or before 12th  
May, 1881:—

1. One Silver Medal for the best sanitary arrange-  
ments, carried out and in satisfactory working,  
in a house let out in tenements to artisans, for  
which a weekly rental is paid.

2. One Silver Medal for the best sanitary  
arrangements, in actual working, in a house of the  
yearly rental of £40, or less, to about £200 in value.

3. One Silver Medal for the best sanitary ar-  
rangements, in actual satisfactory working, in a  
house of the yearly rental value of £200 and up-  
wards, to any amount.

4. The houses must be open to the inspection  
of the Judges, who, in considering their award,  
will be guided by the suggestions of plans for  
main sewerage, drainage, and water supply, made  
under the Public Health Act, 1875.\* The houses  
must have been in actual occupation within the  
last three months, and a Certificate must be given  
by the occupiers, on a printed form, stating the  
satisfactory working of all the sanitary arrange-  
ments, such form to be obtained at the Society of  
Arts.

5. The houses may be old, fitted with modern  
sanitary arrangements, or may be new. They  
must be within the metropolitan area of the Board  
of Works.

6. The sanitary arrangements must include the  
conditions for good water supply, drainage, warm-  
ing, and ventilation of the house, and precautions  
taken against frost.

7. The medals may be awarded to the occupiers  
of the houses, or the lessees, or the owners.

8. The plans must consist of a ground plan and  
sections, to the scale of not less than one inch to  
five feet; details of not less than one inch to the  
foot. The plans may be accompanied by speci-  
fications.

9. The names of the architects, surveyors, or  
sanitary engineers who directed the sanitary  
arrangements should be given, and Certificates  
will be awarded to those whose plans obtain the  
Medals.

(By Order)

H. TRUEMAN WOOD, Secretary.

\* The Public Health Act has been revised to 1878, and published  
by Her Majesty's Stationery Office. Price, with plans, three  
shillings.

**DOMESTIC ECONOMY.**

1. The Council will hold a Third Congress on Domestic Economy, at the Society's Rooms in the Adelphi, London, during the present year.

2. The Council offer Seven Bronze Medals, and Certificates of Merit for Papers (not exceeding 1,000 words), written by Teachers of Public Elementary Schools and Training Colleges, which shall give an account of the best method practised by the teacher, of the teacher's experience, and the result of the teaching, in any one or more of the seven classes of subjects named below.

3. The Education Department, in the Code of 1880 (p. 31), classes the following subjects under Domestic Economy for Girls:—

The First Branch includes—

- (a) Clothing and Washing.
- (b) The Dwelling—Warming, Cleaning, and Ventilation.
- (c) Rules for Health—The Management of the Sick Room, Cottage Income, Expenditure, and Savings.

The Second Branch includes—

- (a) Food—Its Composition and its Nutritive Value
- (b) Food—Its Functions.
- (c) Food—Its Preparation and Culinary Treatment (*i.e.*, Practical Cookery) (§ 24).

The Council have resolved to add the subject of Needlework, which will be exhibited and discussed in the Congress, although it is not classed in the Code as a branch of Domestic Economy.

4. Only one medal will be given to a teacher, but the subjects taught successfully will be inscribed on the one medal and a certificate given.

5. The papers must be sent to the Secretary or the Society of Arts by the 1st May next. Each paper must be enclosed in a sealed envelope, bearing a motto, and must be accompanied by an envelope bearing the same motto, and having within it the writer's name and address.

6. No medals or certificates will be awarded if the papers are not of sufficient merit to deserve them. (By order)

H. TRUEMAN WOOD, Secretary.

**LABEL FOR PLANTS.**

The Council are prepared to award a Society's Silver Medal, together with a prize of £5, which has been placed at their disposal for the purpose by Mr. G. F. Wilson, F.R.S., for the best label for plants.

The object of the offer is to obtain a label which may be cheap and durable, and may show legibly whatever is written or printed thereon; the label must be suitable for plants in open border. These considerations will principally govern the award.

Specimen labels, bearing a number or motto, and accompanied by a sealed envelope containing the name of the sender, must be sent in to the Secretary not later than the 1st May, 1881.

The Council reserve to themselves the right of withholding the Medal and Prize offered, if, in the opinion of the judges, none of the specimens sent in are deserving.

**PROCEEDINGS OF THE SOCIETY.****FOREIGN AND COLONIAL SECTION.**

Tuesday, February 1st, 1881; Sir RICHARD TEMPLE, Bart., G.C.S.I., C.I.E., D.C.L., in the chair.

The paper read was on—

**THE INDUSTRIAL RESOURCES OF SOUTH AFRICA.**

By the Right Hon. Sir Bartle Frere, Bart., G.C.B., G.C.S.I., F.R.S., D.C.L., LL.D.

When first proceeding to South Africa, I found the greatest difficulty in obtaining any reliable detailed and recent information regarding its industrial resources, and the same difficulty has struck me since my return to England, when I have been often questioned on the subject by those whose attention had been directed to the English possessions in that quarter.

Much that is valuable is to be found well selected and well arranged in Mr. Silver's excellent hand-book,\* but there is much which could hardly be compressed into any single hand-book, and though I cannot pretend to supply the want, something may be done towards assisting others to do so, if I briefly state, in the course of the present lecture, a few of such facts connected with the industrial resources of the country, which strike a traveller in South Africa, and if I refer to sources whence more detailed information may be obtained by those who desire it.

I have no striking new facts to communicate. I can give you little more than a traveller's impressions, pointing out where my own information has been derived, and offering to answer any questions on the subject which my hearers may wish to address to me after the lecture has concluded.

I must presuppose a general knowledge of the physical configuration and extent of temperate South Africa, and the relative position and general area of the component States, and I must ask you to remember that temperate South Africa is a very large territory comprising:—

1st. The Old Cape Colony, in which may be now included Kaffraria, Basutoland, and Griqualand West.

2nd. The Colony of Natal.

3rd. The Orange Free State.

4th. The Transvaal.

\* Silver's "South Africa." Third edition. Silver and Co., Sun-court, 67, Cornhill. Price 6s.

The Transvaal and Damaraland. Before the area and population of these provinces, bag to refer to the paper I lately read in the Royal Geographical Society, which will be printed, with a useful map, in the number of the Proceedings of that

will bear in mind the various character of the population. Of Europeans we have large numbers of diverse origin. English, Dutch, with sprinkling of French Huguenots, an innumerable number of Germans, and scattered representatives of most other European races. Of men of colour we have those distinguished as the "yellow skinned races," who claim to be the aborigines of the country, including Bushmen, Hottentots, and men of "black," and dark brown complexions, chiefly of the Bantu family, including Kaffirs, Zulus, Basutos, and Damaras. Of mixed races we have the Hottentots and others, besides important classes of origin represented by those known as the "men of Javanese race at the Cape, and the Tamul and other Indian races in Natal. During the seasons and meteorology of the

I can only briefly here notice that for the most part South Africa lies, as they would say in the tropics, between two monsoons, or trade winds, of which the influence is felt throughout the greater part of the country, very regular, but influencing the general climate and themselves much modified by the mountain ranges, which run parallel to the coast, and rise by successive terraces to the interior. To the west there is a really dry summer and a wet winter, to the east we have wet and thundery summers and dry winters. In all cases, we must remember that the seasons of summer and winter are the reverse of those belonging to our own northern hemisphere.

In the history of this country, I will only now refer to the standard works of Mr. John H. Theal, and the excellent school abstract of his work.

The political constitution of a country is of the most important factor in all industrial progress, but I can dwell no more on this point than to remind you that the Cape Colony has representative institutions, with a Ministry responsible to the Legislature; that Natal has representative institutions, but no responsible Ministry; and that the Transvaal is a Crown colony under a Legislative Council, all three being under the direct control of the Crown. The Orange Free State has an elected republic Government, with a president, and is in alliance with, but quite independent of, the surrounding British colonies. Those who would desire to know more on the subject of the various constitutions, may consult Mr. Silver's hand-book, the almanacks and directories of the Cape Colony, Natal, and the Transvaal, all excellent in their way.

#### APPENDIX A.

By Clowes and Son, London, for J. & J. Cape Town. "Good Hope General Directory," Naul Solomon and Sons, sold by White, 17, Bloomsbury-street, London. "Annual Directory, and Register," sold by Alder, 11, 12, Lombard-street, and by G. Street, (publishers of the "Almanack," which is full of useful information) map "Emigrants' Guide to South Africa," 1879, price 1s. White and Co., 17, Bloomsbury-street. "The Emigrants' Guide to Natal,"

The public income and expenditure would naturally require notice, but, at present, I must content myself with referring you to the works I have just mentioned, and to the enclosed papers, which will be printed as an Appendix (B) to this lecture, merely noticing a few salient points in passing.

So with regard to trade and commerce, you will find excellent general abstracts of parliamentary papers in the works I have already mentioned, to which the papers forming Appendix C, will furnish a few additions.

I will now consider, in brief detail, under several heads, the chief industrial resources of the country.

#### MINERAL RESOURCES.

As regards mineral resources, the first place is claimed by coal. It has long been known that considerable coal fields existed in the South African colonies, but, so far as I can learn, there is, in this country, a very inadequate conception of the extent and value of the fields already known; and the researches which have hitherto been made have shown that the known coal fields form but a very inconsiderable portion of those which exist between the sea and the tropic. There appears no reason to doubt that from the neighbourhood of Beaufort West, in the Cape Colony, where the railway from Cape Town at present terminates, coal is to be found in the neighbourhood of both sides of the great line of mountains which follow the direction of the coast from the Nieuwveld Mountains, in lat. 32° S., at least as far as the Oliphants River, in lat. 24° S., and extensive beds are known to exist north-north-eastward from the Transvaal, being on the surface at more than one part of the Zambesi Valley and appearing also on the surface on the Ravooma River.

But let us now consider more in detail the coal in the Cape Colony. Promising indications of coal have been found in the Nieuwveld and Camdeboo Mountains, where boring operations are now going on under the Cape Government, and coal is now extracted to a considerable amount at more than one spot between the line of railway from Port Elizabeth to Graaf Reinet and Beaufort West. In the Stormberg Mountains, and about Molteno and Dordrecht, in the Indwe Valley, the seams are said to be easily accessible and productive, and appear to be of great extent, but the commercial value of these fields can hardly be ascertained until railways, which have now been constructed up to Beaufort West, Graaf Reinet, Cradock, and Queenstown, shall be further extended.

In the Orange Free State, there appear to be vast deposits of coal between Bloemfontein and the Upper Vaal River, in the neighbourhood of Cradock and Winburg; and the reports of Mr. Stowe, a trained geologist, have justified expectations of finding most valuable and extensive fields in the north-eastern portion of the Free State. In a letter dated 6th September last, Mr. Stowe

published by Lockwood and Co., Stationers'-hall-court, Ludgate-hill, full of useful and accurate matter, as might be expected from the author, Dr. E. J. Munn, F.R.S., F.R.G.S., formerly Superintendent-General of Education in Natal. It was, however, published as far back as 1867. It is much to be wished that Dr. Munn would revise it, and bring it up to date. Much later information regarding the colony is to be found in the larger work, "Brook's Natal," edited by Dr. Munn, and published by Messrs. Lockwood and Co., Stationers'-hall-court, Ludgate-hill, 1879.—E.J.

states that he has obtained the refusal of mining rights in 24 square miles of country in the heart of the thickest deposits. Magnetic iron is within 15 miles of coal beds, sometimes upwards of 12 ft. thick.

In Natal, coal has been for some time worked to a considerable extent at Newcastle and Dundee, and indications have been found in other parts, as at Estcourt; but these deposits are not likely to be developed till means of carriage are improved. I have been informed by Dr. Mann, that he found, when he was at Pietermaritzburg, that he could get coal cheaper from England *via* Durban than he could from the field that had then been recently discovered in the neighbourhood of Newcastle. The Newcastle beds, which I visited, appear to extend to a great distance, and to improve in quality in an easterly direction towards Zululand. Before he advanced from Kambula, Sir Evelyn Wood furnished fuel to a great part of his column for a considerable time, from surface beds which he discovered near the then Zulu boundary, and it is clear that these Natal and Zulu beds are of very considerable extent.

On the north-western side of the Drakensberg, beds re-appear, apparently continuations of those above described in the Orange Free State. At Standerton, I found the people habitually using, as their fuel, coal which they carted from an open surface pit a few miles distant; and indications of coal are met with both to the north towards Lydenberg, and westward down the valley of the Vaal River.

At present, all these fields are but little worked, owing to want of means of cheap carriage, but at some places, as at Kimberley, the price of fuel is so enormous as to render it possible to bring this coal in wagons from a distance of several hundred miles. Between Potchefstroom and Kimberley, I overtook several wagons of coal, containing four tons each. It was being brought as a speculation from surface mines between Potchefstroom and Heidelberg, and could, I was told, be sold at a profit after this long cartage at Kimberley; but then it must be remembered that £17 was no unusual price for a wagon load of firewood at Kimberley, so that any substitute could bear long carriage. We may hope that Kimberley will before long be better supplied with means of transport, by which coal can be brought both from the seaboard and the interior. In that case, some cheaper and more powerful means of transport than a bullock wagon must be found, if the Transvaal coal is to be profitably worked. The country is open and well adapted, not only to railroads, but for navigable canals, which could be most easily and cheaply constructed from any part of the Upper Vaal River to Kimberley.

At present, South Africa is entirely dependent for its supply of iron on imports from other countries, but there is abundance of iron ore in the vicinity of coal-beds, easily procurable and easily worked, and only waiting a supply of cheap transport and abundant fuel to enable it to be worked to advantage.

Manganese has been found in several localities. There are mines which have been for some years profitably worked near Wellington, in the western Cape Colony.

Cobalt has been found in rich and easily-worked mines north of Middelburg, in the Transvaal, and

indications have been discovered to the south of the Drakensburg, in Natal.

Lead mines of great richness have been worked at Marico. I met four wagons laden with pigs of Marico lead near Pretoria. The mines have been worked and the lead extracted by Mr. Bray, an enterprising Englishman; and here again better means of carriage were all that was needed to render the mines of great value.

Valuable copper mines have been worked for some time in Little Namaqualand, and the exports of copper ore from Port Nolloth to Swansea are of great annual value. When the mines were first worked in 1854, a copper mining mania prevailed in the Cape Colony. Thirty companies, to dig for copper, were formed, with nominal capital amounting to £1,393,000. Many were ruined by the subsequent crash, and only one copper mining company survived. The average yield from 1858 to 1867 was 4,000 tons of ore.

The railway from Port Nolloth to Ookiep (93 miles in length), has since been constructed by the Copper Mining Company, and the average yield is valued at about a quarter of a million sterling per annum. Still, richer mines are said to exist beyond the British boundary in Damaraland, where a considerable amount of almost pure native copper is found and worked by the Bushmen and wild tribes north of the Damaras.

Great expectations were, at one time, formed of the richness of the Transvaal gold fields, and a considerable amount of gold is even now extracted from the gold fields in and beyond the Lydenberg district about Pilgrim's Rest and Macmac. Much more would probably be worked if the country were settled, but here and in other parts where gold has been worked, as, for instance, in the mountains between Pretoria and Potchefstroom, the gold hitherto found has been, for the most part, in quartz, and cannot be extracted without more machinery and cheaper fuel than the miners have as yet been able to command. To the north and north-east of the Transvaal there are said to be very productive gold fields, from the best portions of which miners have hitherto been excluded by the jealousy of native chiefs. But if I may trust the opinions which have been given me by gold miners of considerable experience in California and Australia, there is some danger that the accidental discovery of a really good field might at any time induce an influx of gold diggers, who would not be content till they had removed all difficulties, political as well as physical, which at present limit this branch of industry.

The great and increasing diamond mines in Griqualand West and the Orange Free State would require more than one lecture to do justice to a subject of such importance. I can only, therefore, here remind you of a few salient facts. It is only fourteen years since the first diamond was discovered in South Africa, and the exports since then have so enormously increased, that in one year more than three and a half millions pounds worth of diamonds have passed through the Cape post-office, besides diamonds of a very large value which were exported in other ways. The principal mines, I need hardly tell you, are at Kimberley. They are found in what appear to be the remains of extinct subaqueous craters, formed by the

of fluid mud and gases which have forced through the sandstone and other strata, it is now the surface, but which seem, when tatters were formed, to have been under a lepth of water. The subterranean forces rmed vast craters, more or less regular in and which, till the diamond digging com-, were filled up with fragments of rock less altered by subterranean heat, and with volcanic indurated clay or tufaceous mud, is still ejected from the active mud es on the Mecran Coast, between Persia lia. In such indurated clay, the diamonds nd embedded. The clay is of stony hard- en first dug out, but rapidly decomposes the influence of the atmosphere, acting on lphate of iron with which it is largely d, and the precious stones are then easily l out.

les diamonds of every variety of colours ster, garnets and similar stones are found, are hardly noticed at all by those who are ing the diamonds, but the collection of may ultimately form a branch of industry. d Kimberley Mine, which has now reached pth of 300 feet without any indication of the supply or the quality of diamonds, is a very regular shaped crater. The ing mines of Du Toit's Pan, Old de Beers, alkfontein, are more irregular in shape, and een less deeply excavated; but it appears, he discovery of diamonds in other "pans," y are called (i.e., depressions indicating of subterranean forces), which are found in s parts of the adjoining country, that the rley mines are by no means singular in the which they contain. The Jager Fontein gs, near Fauresmith, in the Orange Free are already largely worked, and we hear of mines being opened in the neighbourhood. esides the "pans," or "dry diggings," as re sometimes called, where the diamonds e supposed to be found *in situ* in the ted clay which embeds them, diamonds, of them of the finest water and of great have been found in alluvial or "river dig-" near the banks of the Vaal and other

They appear to have been washed out of original matrix, and deposited with gravel alluvial soil near the present course of the

The working of these alluvial mines is laborious, owing to the great size of the rs which have to be removed, and the for the industry expended on them is less, as the diamonds are found very irregularly ted—som-times many together and some none at all—but, when found, they are lly valuable stones, as imperfect stones, and liable to split on exposure, are less com- met with than in what are called the dry gs, in the old craters.

e does not admit of even brief notice of ning communities, which have settled at the ad fields. A very graphic account of the will be found in Mr. Anthony Trollope's *South Africa*. His description, though valuable matter, is not always drawn with a ng pencil. I have extracted from the *South a*, and added as an Appendix\* to this paper,

a very useful and succinct description of the Diamond Fields, by Mr. R. W. Murray, who has been long resident there, and who knows the fields and their inhabitants as well as any living authority.

I may here mention that about a century and a half ago, London was the chief seat of the art of cutting diamonds; but the industry was subsequently removed to Amsterdam, which, till lately, had a monopoly of the business. It has since been restored to England by Mr. W. Ford, of Clerkenwell-green.\* An account of the mode of splitting a diamond, with an illustration of the tools used, is given in the late Rev. Arthur Rigg's Cantor Lectures on "Tools" (*Journal*, vol. xxiii., p. 820).

We are indebted to Professor Tennant for a beautiful collection of South African diamonds and other gems, which he has allowed to be exhibited here this evening.

Fine specimens of asbestos have been brought from the Asbestos Mountains in Griqualand; and agates, cornelians, garnets, &c., though they do not form objects of industry, have been collected of considerable value, and probably would well repay more careful research. They are found in the river gravel in all parts of the lower course of the Orange River, nearly down to its mouth.

Good slate is found in various parts of all the colonies, but English slates are cheap and good. The local slate quarries cannot be worked without an abundant supply of labour and capital, and the slates used are consequently for the most part imported. It is the same with regard to marble, which has been found of good quality near Worcester, and in some of the southern portions of Natal. Of good building stone and brick earth there is no want, and with the exoeption of timber, building materials are almost everywhere cheap and abundant. Porcelain clay, of very good quality, has been found in the neighbourhood of Cape Town, and a factory has been set up for pottery.

Salt is largely produced in the Transgariep territories, and the salt-pans west of the Vaal and Hart Rivers are of considerable value even now.

Before quitting the subject of the mineral resources of South Africa, I may be allowed to bear my testimony to the general accuracy of the indications of mineral resources given on the face of Jeppe's map of the Transvaal. I confess that, before I went to the Transvaal, I was sceptical on the subject, but wherever I had opportunities of testing the information so given, I found that the minerals mentioned by Jeppe were always to be met with, though of course, not always in quantities to pay the expense of mining.

Guano, though of animal origin, may be mentioned here as an object of colonial industry. It is produced on the rocky islets on the West Coast, where there is little rain. Most of the old deposits, on Ichabee and other islands, have been long since cleared away, but there is a considerable amount of fresh deposit yearly, from the myriads of seabirds which frequent the coast in the breeding season, after which, the guano is swept together and collected. The groups of rocks and islets, twenty in number, are leased for various periods of from 5 to 26 years, at a total

\* Vide Appendix D.

\* Vide Appendix D.

annual rent of £2,410, besides the dues levied on the guano collected. The quantities collected during eight years, averaged more than 2,000 tons of guano per annum, valued at £6 per ton, besides sea fowls, eggs, feathers, and fish oil, to an average further value of £2,255 per annum. (Cape Parliamentary Return, 1880.)

#### AGRICULTURAL RESOURCES.

Let us now turn to the agricultural resources of South Africa. Let me, in the first instance, state that from Durban, round by the route which Sir George Colley is now following to Pretoria, and thence, *via* Potchefstroom, to Kimberley and Beaufort West, and so by railway to Cape Town, a course of not less than twelve hundred miles, besides other visits to the Kaffir frontier and many districts between Port Elizabeth and the Baashi River, I have seen enough of South Africa to gain a very good general idea of the character of its soil and other requisites for agriculture. Throughout the whole distance I have travelled I find it difficult to recall more than a mile or two at a time of barren and unfertile country. Mountains there are, and stony wastes, where there is barely food for more than a very small number of sheep to the square mile; but, of hopelessly unprofitable land, except on the mountain ranges, it is difficult to find more than a few patches here and there. On the other hand, the country abounds in long stretches of extremely fertile land, such as would be valued in any country in Europe, and with every variety of climate similar to what would be met with in the northern hemisphere, from the extreme north of the temperate zone to the semi-tropical regions of Northern Africa. In parts, especially in the Transvaal and on the coast, the pasture for large cattle is extremely rich and abundant, and further away from the coast the country is admirably adapted for sheep farming. It is a peculiarity of South African pasture that it is as often found upon shrubs and bushes as among the grasses of the field. Some of the districts where the Merino sheep flourishes best, possess hardly a blade of grass, but there is abundance of food to be found in the shoots of various plants, chiefly aromatic in scent, and adapted by habit to resist long droughts. On these the sheep thrive, and can produce as good wool and mutton as upon any downs in England or Spain.

Water is abundant in most parts of South Africa, to the extent required by the farmer. It is not always on the surface, indeed, in many vast regions, it is very rarely to be seen on the surface, and such districts have hitherto, in many cases, been accounted barren and uninhabitable, except for a few months after rain; but the farmers are now becoming alive to the fact that, below the surface, even in portions of country which have hitherto been supposed to be quite arid and unprofitable, water is generally to be found by digging at moderate depths; and I can testify, from my own observation, that, in many districts where want of water is now much complained of, it could be found if the people would only expend on well-digging the ordinary amount of labour which is required for agricultural existence in most parts of Central India, Rajputana, and the Deccan. But there is a still greater field for increasing the present water supply by means of canals, which

might, to an enormous extent, be drawn from the rivers in almost every part of the country. Much has been already done on a small scale by farmers; and on some of the large farms in the Karroo, I have seen thousands of pounds expended by farmers in what are locally called dams, or reservoirs formed by embankments across valleys, and by what are called "leading furrows" from running streams.

For wells, and for such small works of irrigation from streams, the country may, I think, safely trust to the enterprise and capital of individual farmers; but I hope the time is not far distant when the Government in South Africa will turn its serious attention to large schemes of irrigation from the great rivers with which the country abounds. It is not necessary to go to Africa for the purpose of satisfying one's self of the immense returns which would follow such a system of large irrigation works from some of the more considerable streams, on the scale of which every province in India affords so many examples. If we look, for instance, at either the Orange River or the Vaal on any large map, we see the course of large perennial rivers, which carry an abundant supply of water even in the driest months of the year, and after the most prolonged droughts. They are fed, in fact, from springs in the great ranges parallel to the coast, which never fail to have a supply of annual rain, however much the low country may suffer from the want of it. These streams run in the earlier part of their course frequently over rocky beds, affording every facility for dams such as are required to turn the course of the stream into channels excavated at the side. A very short distance of such excavation would suffice in almost every case to lead the water clear of the deep river bed on to the level of the country around, which has a gradual slope, generally westward and northward, enabling a canal to be carried for hundreds of miles over undulating country, which appears as if made for artificial irrigation, continuing down the course of those great rivers to within about 100 miles of the great Atlantic Ocean.

On a smaller scale, the facilities of most other rivers which have a course northward or westward from the great mountain backbone of the continent are quite equal to those of the Orange River and the Vaal. Even the sandy river beds which traverse so much of the Karroo might be turned to valuable account by works of the kind I have indicated. All these river beds are the channels of a flooded stream once or oftener during the course of most years, and carry, during such temporary floodings, a vast quantity of water which now runs to waste into the ocean. In any part of India such streams would be utilised by making them give a thorough soaking to a dry plain at some distance down the valley, or they might be made to fill artificial reservoirs which are formed by damming up the lower extremities of hollow valleys, and they would thus furnish, if not water for cultivation, certainly the water required to maintain large flocks of sheep and cattle.

As a rule, the streams which run south and east from the Drakensberg, and the other ranges which run parallel to or in continuation of that great mountain chain, are less promising subjects for irrigation engineering, on a large scale. They

ally have a course of steeper gradients, and a deep and comparatively narrow valleys. Even on these, there is ample room for the able expenditure of a large amount of capital. Hence, attention has already been directed, as to the Orange River, between Port Elizabeth and Graaff-Reinet. The Breede, the Berg, the Oliphants and many others which might be named, flow through a country covered by valuable farms, the extent of which might be far more than doubled by extensive irrigation works on a comprehensive though very little has as yet been done to take advantage of the natural resources which these rivers afford.

The Cape does not admit of more than a very brief mention of the various breeds of cattle. There are many native breeds which have valuable qualities of their own. The small and hardy Kaffir and Zulu are valuable for their meat and milk. The Dutch cattle are of larger size, and have larger horns, reaching more nearly to the African deer breeds. They appear to be a cross between European—probably Dutch—cattle and those which were found in possession of the Hottentots when the Dutch arrived in the country. Of late years much has been done, with some success, to introduce the valuable and improved breeds of Europe. The best large farms of the more intelligent class of farmers, some of the best English breeds have been tried, with varied success. Shorthorns, however, excellent in other respects, are rather less common, and more delicate in constitution, than those of the country. Alderney and Kerry cows are generally to be found near large towns, where they are in demand; but with very few exceptions, it can hardly be said that any very systematic attempts have been made to improve, by crossing, the native breeds which experience shows are most valuable in the country. It must be remembered that at present, and probably for some generations to come, the quality of cattle for draught will still mainly influence the views of the South African farmer-breeder. Railways will, I trust, rapidly diminish the use of the horse and mule wagon will come into increased use; but the ox wagon is, in so many respects, adapted to the country where no made roads are to be found, that it will be a long time before it is entirely superseded by quicker means of transport.

**Sheep.**—The Cape has long been celebrated for the excellent quality and cheapness of its horses. They appear to have been originally of Spanish, or Portuguese stock, and in this respect resemble the breeds of South America; but, for some time past, especially since Lord Charles Somerset was Governor, great efforts have been made to improve the original breeds, by means of importation of the best English stock. Most parts of the colony, except the warmest of the coast districts, seem admirably adapted by nature for horse-breeding. Breeders from Australia, as well as from England, generally object to the small extent of shelter and artificial food which is afforded to the mares and colts, and consider that the Cape system of treating breeding stock is much rougher and less artificial than they would have it be. I do not pretend to pronounce any opinion myself on this point, but any visitor to the Cape who may wish to see horse-breeding on a large scale, as managed by some of the most

intelligent and successful of Cape stock-breeders, should apply to Mr. Melk for permission to visit his farm on the Berg River, about 90 miles to the north of Cape Town, where they would have opportunities of seeing South African cattle-breeding in its greatest perfection.

The Cape Colony was almost entirely swept of its best stock of horses by the demands consequent on the Indian Mutiny in 1857, when a great number of horses of the best breeds were exported to India. A time of considerable agricultural depression followed, and it can hardly be said that Cape stock has yet recovered from the depletion of 24 years ago; but this is more owing to the enormous demand caused by purchasers from the interior than from any falling off in the production of stock. The establishment of the Orange Free State and Transvaal republics, and the opening of the Diamond Fields, greatly increased the former demand for horses in the interior, and to this, more than to any falling off in the production, must be attributed the present scarcity and dearth of horses in the best breeding districts of South Africa.

Mules are, in some respects, even better adapted for purposes of draught than either oxen or horses in South Africa, and increasing attention is being directed to the breeding of this kind of stock, but it does not yet meet the demand, and many hundreds of mules are annually imported at present from South America.

Sheep are, as in Australia, one of the staple resources of the South African farmer. The sheep of the country is, as I need not tell you, a very different animal from any European breed; long-legged, with hair instead of wool, and with the enormous fatty tail which distinguishes many of the African breeds of sheep. It must be a very ancient breed, for I have seen onyx images of the black-headed Berbera sheep which is common in North-East Africa, the black head and white body of the sheep being imitated in the black and white of the onyx. These images were found in Egyptian mummies at least 2,000 years old, and resemble the sheep put on board the P. and O. ships at Aden. The Hottentot sheep has its merits, owing to its extreme hardness and power of resisting privations of food and water, which would destroy almost any other breed; but, except for its meat and its skin, the Hottentot sheep is of little value as compared with any European breed. Men are still living who have had the honour of introducing Merino sheep, or some cross from Merinos, into their own district, and good stories are still told of old-fashioned farmers who, on the first introduction of the Merino breeds, derided the foolish adventurers who offered to pay them for the privilege of "cutting the hair off their sheep;" but such stories relate to a past generation, and at present every South African farmer is alive to the value of his wool-bearing sheep, and keen in discussing the best means of improving them. There is, however, a great want of scientific intelligence among many sheep-farmers as regards the diseases of sheep, the evils of overstocking, and of too frequent shearing, careless breeding, and insufficient shelter and food at lambing time. The Cape Colony is still behind Australia in the attention it has paid to the prevention of scab, by enclosure laws,

Scab Acts, Acts for the extirpation of burr weeds, such as the *Xanthium spinosum*, and other legislative provision for protecting the improving sheep-farmer from the results of his neighbours' carelessness or ignorance. The water supply is a question, of course, of primary importance to the sheep-farmer, and increased attention is every year being paid to means of providing water for sheep pastures by well-sinking and pumping. There are probably millions of acres in South Africa which might be turned into profitable sheep-walks by the irrigation engineer, the well-sinker, and the English manufacturer of inexpensive means of raising water by machinery.

*Angora goats* are, I believe, of comparatively late introduction, the first having been brought to the colony by Mr. Mosenthal. They appear to thrive in most of the drier climates of the colony, and this branch of industry is likely to receive annual development as the means of transport in the colony improve.

*Ostrich Farming.*—Time does not admit of my saying more than a few words on this new and most profitable branch of industry. It is but a very few years since the idea of taming the birds which thrive wild in most parts of South Africa, occurred to an intelligent colonist, and when I first went to the Cape, ostrich farming was still looked upon as rather a fancy occupation, not quite worthy the notice of a steady-going, old-fashioned farmer; but the extraordinary profits which have since been realised, have produced a kind of mania on the subject, and in every part of the old colony ostrich farming is very rapidly extending. I have seen some farms where the stock was obtained quite recently by securing broods of wild birds accidentally found on the estate; but the production of eggs, and the hatching young chicks for sale, is now a recognised branch of farming industry in almost all parts of the western province. There are very few parts of the country which are naturally unfitted for rearing ostriches, and there are some districts, such, for instance, as the extensive unreclaimed bush lands to the north and east of Grahamstown, which appear peculiarly adapted to ostrich farming, and which have hitherto been almost unprofitable for anything else. The birds require, probably, less artificial food than any other stock of equally productive value. Cuttings of prickly pear, the great white arum, almost every kind of succulent vegetable, maize, and millet, besides the natural food they find at large, appear to suit them, and if they have ample space to move about in, they seem very little liable to artificial diseases. To watch them, to hatch the eggs, and to rear the chicks, require very little more than the ordinary constant attention which would be needed for looking after domestic poultry, while the returns, whether from eggs, young birds, or feathers, are very great with reference to the proportion of outlay, either of land, capital, or labour. But, like every other kind of farming, to render it a success, it requires careful and continuous, patient, personal attention, and many young adventurers whom I have seen going out to Africa expecting to invest a few hundred pounds in ostrich farming, and to live like gentlemen on the proceeds, without care and trouble to themselves, are, I am afraid, doomed to disappointment. I must

refer to published works for detailed description of the management of the birds, which is full of interest and amusement to those who are fond of domestic animals. I will only notice one peculiarity of ostrich farming, that when tried on an exhausted sheep-walk, it is found that a few years of use of an ostrich run restores land which has been exhausted by over-stocking, and renders it again capable of feeding a suitable number of sheep. I have often been asked whether I thought the present demand for ostrich feathers would last. I could only reply that the liking for such feathers was one of the few points on which the taste of the most barbarous savage agrees with that of the civilized races; that a perfect ostrich feather, like a good precious stone, is a beautiful thing in itself, and that the fashion for wearing ostrich feathers has endured among great people for more than 4,000 years, as is shown by the sculptures of Assyria and the paintings of royal tombs in Egypt.

Before leaving the subject of stock breeding, I would ask attention to the hope, which seems justified by the success of ostrich farming, that the science and patience of some future South African agriculturist may turn to account the good qualities of some of the indigenous animals, which are fast disappearing from South Africa, and also enrich the South African farmer by further importations of foreign domesticated animals. For instance, there can be little doubt that wherever the African buffalo thrives, there the Indian buffalo, which is so valuable for milk, and for heavy draught, and so inexpensive to keep, would be found to thrive; and it is more than probable that if proper pains were taken, the African buffalo, or cross from it, might be domesticated. There are also, among the llamas and alpacas of America, and the wool-bearing goats of Europe and Asia, other animals besides the Angora goat which would be found profitable. I am aware that experiments have already been made in this direction, but as far as I could learn, they failed, not from any natural incapacity of the country to support the imported animal, but from some defect in management.

So, with regard to camels, there can be no doubt whatever, I think, that the Arabian or Asiatic camel would thrive quite as well in South Africa, as it does north of the Sahara Desert and in Somali-land, and would be a most valuable addition to the means of transport in many parts of South Africa. I, myself, made an attempt at importation; owing to its arrival at the rainy season, and the impossibility of attending to the animal after its arrival, the attempt was not successful; but nothing could be better adapted to the camel than most parts of the Karoo country, which I have seen, and it would probably be still more valuable in the sandy tracts near the Kalahari Desert, and north of the Orange River.

Attempts have been already made by the Khedive of Egypt and Colonel Gordon, to utilise the elephants of northern Africa, as they were, no doubt, made use of by the Carthaginians and Romans. The king of the Belgians has spent large sums in similar attempts in Central Africa. The African elephant is fast disappearing. In the old Cap Colony, a few are still carefully preserved in the forests round Knysna, where H.R.H. the Duke of Edinburgh shot one, and in the Adda Bas

between Port Elizabeth and Grahamstown; but it is rather to the northward, I think, that it might be worth the while of enterprising speculators, as well as of the Government, to make experiments on a large scale, with a view of ascertaining whether the indigenous aboriginal elephant could not be made as useful for purposes of carriage and transport as in India or Ceylon. I have heard from colonial hunters well authenticated stories of the destruction of scores of elephants at a single battue, when they had been driven into deep marshy ground on the borders of Lake N'Gami; and not a wild elephant is now to be found within many hundred miles of the places where, within my own memory, Sir William Harris and Gordon Cumming saw elephants in herds to the number of hundreds in one day. There are parts of the present colonies where, no doubt, a tamed elephant might thrive and be profitably used, and from the Tugela northwards there is probably very little of the coast country where they would not supply, to a great extent, the present want of efficient means of carriage.

It may not be out of place that I should mention the possibility that some of the less productive arms may, at no distant period, be turned to account as game preserves, like the red deer forests in Scotland. I know gentlemen, such as Mr. Alexander Vanderbyl, who have enclosed romontories on the southern coast, containing some thousands of acres, where they have preserved the indigenous antelopes of the country, and can offer a day's shooting, comprising at least a kinds of African antelope, besides the partridges, storks, and pheasants, as they are called, of the country. The bush-buck, the rai-buck, and the other appear, wherever a tract of bush is allowed to rest without much intrusion from woodcutters. The spring-bok appears periodically in such multitudes, in the districts bordering on the Orange River, that I have seen applications to Government that the farmers might be allowed to destroy the bucks in the close season, as a means of preventing their eating up the sheep pasture; almost every species of African antelope will thrive and multiply in enclosed tracts, if only preserved from destruction by the sportsman.

Time does not admit of more than the briefest possible allusion to the resources for arable farming in South Africa. As a general rule, it may be said that, with the exception of garden lots, very few farms are cultivated to the full extent of which they are capable. This is partly owing to the abundance of land, partly to the old colonial mode of isolation, and partly to the want of adequate supplies of capital and labour. But on every hand we see evidences of progress and improvement. The old Dutch plough, and the old fashion of tramping out the grain, are giving way to the newest ploughs by Ransome, Howard, and other European and American makers. The steam plough has been imported and used. Many farmers in the western provinces use reaping and thrashing machines, and mowing machines have been introduced into Natal. But these things are to be seen only here and there, at rare intervals, and only a beginning has been made of improved farming on scientific European systems.

It is very rarely that an attempt has been made to meet the uncertainty of the seasons, by saving

hay or roots for feeding cattle, though in most parts of the country oat hay is cut and stored for forage. But a very large field is open for improvements in all these branches of farming.

So with regard to cereals. On wheat-lands the finest crops of wheat are apt to suffer from rust, but I doubt not some scientific farmer of the future will introduce kinds less liable to this disease.

Millets in all varieties seem at home, as well as Indian corn—or "mealies"—in every part of South Africa, but some of the best kinds of Indian and American origin have not yet been tried.

Vines are among the established agricultural resources of the western colony, but little has been done to improve on the old methods of vine growing and wine making brought to Africa by the original settlers.

In Appendix E will be found a memorandum, with which I have been favoured by Mr. Goodliffe, describing steps lately taken for the improvement of wine farming and wine making in the Cape Colony; and I have no doubt that a new era is before the South African wine grower, more especially if the wine duties in England are remodelled on the principles lately recommended by the Select Committee of the House of Commons.

The fact that Cape wines gained prizes at the late Paris Exhibition shows that, when properly managed, they will yet bear comparison with European vintages.

We have yet to notice many valuable articles of semi-tropical produce, for which the warmer regions of temperate South Africa are well adapted. Natal has already established a name as capable of producing coffee and sugar. Of coffee, the crop in 1870 was 960 tons; since then the production fell off, chiefly owing to want of experience and knowledge of the best mode of treating the plants, and is only now again on the increase. The causes of this temporary decline will be found described in a memorandum, with which I have been favoured by Mr. Walter Peace, the emigration agent for Natal, and which is annexed as Appendix (F).\*

For details regarding the production of sugar, I must refer to the same paper by Mr. Peace. It is said that the last crop will yield 15,000 tons of sugar, of an average value of £20 per ton.

I cannot give a better account of the agricultural resources of Natal, than by quoting the annexed extracts from the address of Mr. W. G. Baker, president of the Pietermaritzberg Agricultural Society, at the annual meeting of that society, in October last, for which also I am indebted to Mr. Peace.\*

It will be seen that tea planting has also been tried with success, and that all the smaller articles of semi-tropical produce, such as red pepper, tapioca, and arrowroot, afford profitable returns.

Tobacco is already grown to a great extent in Oudtshoorn and other districts of the Cape Colony, and on most good farms in the warmer portions of the Transvaal. Looking to the great and increasing consumption of tobacco in all parts of South Africa, among natives as well as Europeans, there may be no doubt that tobacco may become a great staple of South African agricultural industry.

\* Vide Appendix F.

On the great value and necessity for tree planting on an extended scale, and of the immense benefit which a good system of forestry would be to South Africa, I cannot now dwell, nor on many minor resources of industry connected with agriculture, such as the abundance and value of fruit crops of almost every kind suited to a temperate climate, the drying and preserving of which afford profitable occupation to many upland farmers.

Turning now from the land to the ocean, I can only briefly glance at the resources afforded by the fisheries on the South African coasts.

Table Bay, and False Bay, as well as Algoa Bay and Saldanha Bay, were formerly great resorts of whalers, but of late years, this branch of marine industry has fallen off, and though whales are still abundant in the seas of South Africa, the whole fishery is confined to an occasional American ship, the master of which does not always devote his exclusive attention to whaling. The seal fishery also has disappeared, though seals still visit in small numbers the rocky islets in the neighbourhood of the Cape; but there is a large and increasing demand for the fish, which are caught and cured in great numbers in the neighbourhood of Cape Town, as well as along the coast to the northward, and form a large item of export trade to the Mauritius and other places.

On the West Coast, north of Saldanha Bay, there are but two ports at present frequented by sea-going steamers, Walwich Bay, on the coast of Damaraland and Port Nolloth, the port of the copper mining district, just south of the Orange River. Neither affords complete shelter to vessels of any considerable size, nor could either be improved in this respect without the expenditure of a considerable sum of money; but there can be no doubt that much might be done to improve the facilities of landing and shipping on this coast, if it were carefully surveyed, and the natural landing places improved by beacons, lights, and similar appliances.

**Harbours.**—The coasting as well as the ocean-borne trade of South Africa has been much restricted by the want of good natural harbours. All the large rivers have bars at their mouths, which prevent their being much used for purposes of trade, and, from the Portuguese frontier on the West Coast, in lat. 18°, round to Delagoa Bay on the East Coast, in lat. 26°, with the exception of Saldanha Bay, there is not a single perfectly safe natural harbour where large ships can lie at all seasons, and take in or discharge cargo without inconvenience. Saldanha Bay will, no doubt, in time, be connected with the railway lines in the vicinity of Cape Town, and will become a valuable port. At present, it is hardly ever used, except as a quarantine station. Table Bay is an anchorage secure from easterly and southerly winds, but open to the north and west. Its natural defects in this respect have, however, been, to a great extent, supplied by the breakwater (the first stone of which was tipped by H.R.H. the Duke of Edinburgh in 1860), and which is still in progress of extension. It has already rendered the anchorage safe against the dangers which, in former years, have strewn the coast of Table Bay with wrecks of large vessels. The Alfred Docks have supplied the means of receiving and discharging cargo, alongside a wharf, to all but the very largest class of shipping, and even

these will, at no distant period, be accommodated by the extension of the docks and jetties now in progress. Graving docks, slips, and other appliances are also either completed or in course of completion. It is only necessary to carry out the designs of Sir John Coode, in order to enable Cape Town to take its place as a port furnished with every desirable convenience for mercantile marine.

Simon's Bay, an inlet on the shore of False Bay on the other side of the Cape peninsula, is an anchorage safe at all seasons and in all winds for ships which are well found in ground tackle and it has the appliances of a small naval arsenal, but it is deficient in the necessary means for cheap and rapid discharge of cargo, and is as yet unconnected with Cape Town by railway, though only twelve miles distant from the present terminus.

Algoa Bay is an open roadstead, owing its facilities for carrying on trade to its excellent anchorage, and for putting to sea should it come on to blow heavily from the exposed quarters. Everything which enterprise can do has been done to facilitate landing, short of the construction of harbour works, and these, I trust, will not be long delayed, for it is evident to anyone who has paid much attention to harbour improvement that there is an existing trade at Port Elizabeth which would justify such an outlay as is estimated for the improvement of the harbour; and there can be little doubt, from the high character of the engineer, that any sums laid out on the completion of Sir John Coode's plans would be well applied.

Port Alfred, at the mouth of the Kowie River, is a bar estuary, which is being made available for sea-going ships of moderate burden by works which will make this a very useful port.

The same may be said of East London, at the mouth of the Buffalo River. There seems no reason to doubt that Sir John Coode's plans for the improvement of this estuary will be successful, and make it a valuable port for all the Kaffrarian frontier.

The St. John's River, in Pondoland, is a natural estuary, requiring, apparently, harbour works of no great extent, or probable expense, to render it a most useful channel of trade, but the surveys for its improvement have only lately been completed, and no plans have yet been laid out for the harbour works needed to make the bar passable. The anchorage inside is of great extent and perfectly sheltered.

Durban, in Natal, is already a port carrying on a very large trade, though the harbour is readily accessible only to small sea-going vessels; and little progress has been made in removing the bar, which would enable it to accommodate large vessels. These are at present obliged to remain outside, and discharge and receive cargo as in an open roadstead. Various plans have been devised for the improvement of the Durban harbour, and large sums have been expended, with very little effect, chiefly because it is only lately that the authorities have consulted an experienced harbour engineer, with a view to the systematic and perfect improvement of the harbour. Sir John Coode has furnished plans which, I have reason to think, would be approved in all their main features by his professional brethren, and there can be no doubt that Durban might be made an admirable harbour, adapted to

sea-going ships of the largest class, by works not more expensive than those which have converted the port of Kurrachi, in Scinde, from a small coasting port, a little better than a fishing village, into one of the principal ports of the Indian Empire. The resemblance between the two harbours is most striking, and having watched the Kurrachi harbour works from their commencement, and seen the general improvement of the harbour, I cannot but regret the delay which has hitherto occurred in acting upon Sir John Coode's recommendations with regard to the port of Durban.

Delagoa Bay is a good natural harbour, where ships of any size may load and unload in safety, even in the present unimproved condition of Lorenzo Marquez, the seat of the local Portuguese Government. The port is admirably situated for the wants of the Northern and Eastern Transvaal, besides a great extent of fertile coast country in its immediate vicinity. The Maputa River, running south from the bay for 60 miles as the crow flies, in the direction of Zululand, gives valuable water-carriage to Tongaland, whence large numbers of labourers come to work in Natal and the Cape Colony. Other rivers, which discharge into the bay, afford similar facilities, to a less extent, in other directions, the land all around being extremely fertile, and well adapted for sugar and rice. It requires only a settled government, able to protect life and property, for its development. It is a standing cause of complaint with many of those who are anxious for the progress of South Africa, that this harbour was awarded to the Portuguese by arbitration, but I would put it to those who wish for the development of trade in this direction, whether it would not be better that we should avail ourselves of the advantages held out by the Portuguese port, rather than indulge in unavailing regrets that the port does not belong to ourselves? Nothing can exceed the liberality of the terms of the treaty concluded by Mr. Morier, H.M. Minister at the Court of Lisbon, with the Portuguese Government, and the treaty would probably have been ratified and made use of ere this, had the English mercantile community, who are interested in the development of those countries, shown that they appreciated the advantages held out to general commerce by the treaty, and pressed her Majesty's Government for an early ratification of the treaty by both Powers. The treaty provides that British goods should be admitted free of custom dues in bond; that the English Government should be allowed to build bonded warehouses to any extent; to connect such bonded storehouses by rail with the frontier of the Transvaal; and so to import goods free of Portuguese customs through the Portuguese territory. No greater facilities in these respects could be afforded if the port were in our own hands, and, judging from what is done elsewhere, there would be no insuperable difficulty in obtaining from the Portuguese Government such additional improvements in the facilities for landing and shipping goods at Lorenzo Marquez as English traders might require.

Before quitting this subject of harbours, I would note that I have enumerated only those which are already open to ocean trade. There are others which might be improved at no great expense, and will, I have no doubt, at no distant period, be

thriving ports for a considerable local and coasting traffic. Some, like Mossel Bay, are good roadsteads, where a large and increasing trade is already carried on, though the means of landing or shipping cargo depend on the weather. Others, like the Knysna, are already accessible as far as depth of water is concerned, and are well sheltered, but require better communication with the interior through the mountain ranges which encircle the harbour, and such appliances as a good steam-tug, to make the narrow entrance safe for sailing vessels. Others are bar harbours, like the Berg and Breede Rivers, and are at present frequented by small coasting vessels, but might be made accessible, with a considerable amount of inland river navigation, by such works as have rendered so many of our own bar harbours in England available to ocean commerce. But it is only within the last few years that the commercial public in South Africa has been awake to the necessity for such harbour works. I have no doubt that every year will witness further improvement in this respect, bearing in mind the cardinal truths which apply to harbour improvement in every part of the world, that it is waste of money to follow any but the best scientific advice; that the best scientific advice always makes the utmost possible use of natural forces as means of gradual improvement; that all permanent improvements must be gradual, and that no great improvement can be expected, until the whole of the works designed for removing obstacles by the scientific engineer have been completed.

*Steamer Lines.*—I need not dwell at any length on the great development of steam communication with the Cape, the history of which would alone afford ample materials for a long lecture. It is sufficient to note that the companies of Messrs. Donald Currie and the Union Company each run during the greater part of the year a large steamer every week, and sometimes two, between the Cape and England, the lines from the Cape being extended to the Eastern ports as far as Delagoa Bay.

While on this subject, I would notice the great field for development of commerce on the western coast, which would be opened by the employment of steamers between Table Bay and the Portuguese possessions. There is already a line of steamers, subsidised, I believe, by the Portuguese Government, and managed by a Hull Company, between England and Benguela, the southernmost port on the west coast belonging to Portugal. There is already a growing traffic, which affords employment to a small steamer between Cape Town and Walwich Bay. Much more might be done, if the service were more regular, and carried on by better steamers. Even with the present amount of traffic it is probable that a line on this coast would find ample employment, and still more, should a land line of telegraph be carried through Damara-land and the Portuguese possessions as far as the Congo, on the West Coast.

*Telegraph Lines.*—I cannot here do more than advert briefly to the increasing facilities for commerce afforded by the development of telegraphs. The ocean cable has been lately completed between Durban and Aden, and the network of land lines.

has now extended to most of the towns and larger villages in British South Africa.

*Railways.*—As regards railways, also, I can here only briefly state a few salient points. The total length of lines at present open, or likely to be opened in the course of the next few months, in the Cape Colony, is 959 miles of Government railways, and 98 of line made by the Copper Mining Company. The lines are shown on all the modern maps of the colony, and extend (1) from the Cape Peninsula to Beaufort West; (2) from Port Elizabeth to Graaf Reinet, with one branch to Grahamstown and another to Craddock; (3) from East London to Queen's Town. All these lines are likely to receive early extension from their present termini, till they converge and reach Kimberley and the Orange Free State, and till Grahamstown is connected with Port Alfred at the mouth of the Kowie.

The Natal lines at present extend no further than from Durban to Pietermaritzberg, with short branches parallel to the coast; one running north, the other south. It is a question locally much discussed, whether the Pietermaritzberg line shall be extended in the direction of Ladysmith and Harrismith, or of Newcastle. The total length of rail completed in Natal is 105 miles.

I understand there is a project for a line in continuation of that from Durban to the Tugela, which shall ascend to the east of Zululand, through the country under Mr. John Dunn's chieftainship, so as to tap the coal-fields in that direction.

A line from Delagoa Bay to the Transvaal is of the utmost political and commercial importance, and is not likely to be delayed long after order is restored in the Transvaal. I believe that the extension of the railway system is one of the most potent factors in promoting the peaceful development of all South Africa. The Cape lines hitherto made are paying well, and will, when extended to Kimberley, enormously increase the commercial facilities of the country, without imposing any tax on its finances.

In these brief remarks, I have endeavoured to give to the industrial classes of these islands, through the widely circulated *Journal* of the Society of Arts, some faint idea of the industrial resources of the great country where I have lately sojourned. It is a country with a history, but a history confined to the deeds of men, our kinsmen in blood, and almost of our own times. Many thousand years must have elapsed since the South African continent took its present shape; the great basin of the Orange River and its tributaries, with their diamond fields and gold fields, their deserts, and their fertile pastures; the rock-bound coast; the great mountain ranges, which rise to the Drakensburg peaks, all were, probably, thousands of years ago, as they are now, in outline and climate, in clothing of plant and tree, and in the wild animals which abounded within living memory; there is no evidence of much change in natural form or feature for forty or fifty centuries before Europeans came to colonise. But history there is none of South Africa—save vague traditions, or such records of pre-historic man as bone caves and gravel beds may yield—till we come down to the days when the bold seamen of Portugal planted the cross on each

great promontory as they weathered the road by which English, French traders might follow them to the Indies.

The country has, however, a great history, but it is a history yet to be made by European lineage, who have chosen it as such. As the traveller passes over league after league of almost uninhabited country, and marks the access, and the ease with which all the of civilised European life can be sundered questions force themselves on him, how land, so favoured by Nature, to remain inhabited by civilised man, the heritance of animals, or the abode of a barbarism grades mankind almost to the level of that perish?

And then it was impossible not to think of thousands of civilised, industrious, men and women, who, in our north-populated country, are wearing out their lives in a ceaseless struggle for a bare existence, difficult to resist the conviction that South Africa, was ample room for many myriads of such men to find the means and of rising to comfort and independence, are daily becoming more difficult of within the narrow limits of our own land.

But for such men as I have described, I resolve to make South Africa their home. I believe, a higher destiny than merely even than helping to form a nation.

Thinly scattered throughout the whole are tribes of various native races, on peculiarities seems to be that they have settled, never had a resting-place, in which, for many generations together, call their own. They have no historical memory of endless migrations, pursued; as conquerors and exterminators the victims of conquest and extermination oldest or most intelligent can but repeat dreary memories of how they came from the northward—from regions where a greater, more civilised, and happier than they are now; how, driven by hostile tribes, they sometimes rested generations in the same region, and, of superior courage and sagacity, slaughtered, drove out, or absorbed the clans, only to be in their own turn slaughtered, or absorbed by some yet more numerous savages; or driven to temporary homes, to resume the ceaseless migrations of thousands of years past.

Yet are they a people of excellent, physical and intellectual qualities, many of them far more than the negroes of Central Africa, and all but more or less traces of having been gradual from a state of higher civilisation and complete humanity. They are capable of adopting all that we can give them in arts of peace, the means of civilisation, the great truths which are the secrets of individual happiness here on earth, and only sure lights in the darkness and future existence. I have known many of the native races, endowed with natural gifts no way inferior to the average

to make their mark in intellectual or political power even amongst ourselves. These are their capabilities. What is needed for their development? Nothing, I believe, but settled order and government—of our modern European type—a Government that can frame laws, and enforce them, which can defend life and property, and enable its citizens, as long as they obey the law, to prosper and advance in freedom and happiness, each according to his individual qualities.

Good Governments already exist in South Africa.

Nowhere seen a Government which reproduces so fully and accurately as that of the Cape Colony, the conditions and possibilities of social and political life, which we so value here in England. A Government is possible under the English system in every one of the South African States without exception; and under such Government freedom of toil from this country may live and prosper, in unity with his fellow-subjects of every race; and in such Government all may have their share, as subjects of the British Crown.

There was a time, so historians tell us, when the Aryan ancestors of our own swarmed forth from Central Asia, some towards India, others towards Europe, north and south, to occupy the various places of the earth, and to become in the course of long ages the parents of great and civilized nations. A swarming of the same kind set in centuries ago, from our own land, and has continued increasing till America and Australia are Northern Europe as the parent of us and growing nations which had no existence when the Cape of Storms was first discovered. South Africa is later in the field as a home for immigrants, but with capabilities to receive the undisturbed myriads of Europe for many generations to come.

Native races, which have so long been regarded as insuperable obstacles to the progress of

the country, will, I feel assured, at no distant period, be acknowledged as valuable elements in South African nationalities; for, in South Africa, I believe, the Government is ever anxious to act in accordance with the great truth which Englishmen have never been slow to recognise—that our duty with regard to races, inferior to our own in civilisation and power, is to do to them as we would have our Government do to us—to rule and protect them; to teach, to guide, and to elevate them; and not to enslave or exterminate them.

## APPENDIX A.

### METEOROLOGY.

The best account of any South African climate I have seen will be found in a full and comparatively late, as well as most interesting, chapter on the Natal climate, at pp. 59 and 105 of "Brook's Natal," edited by Dr. Mann, and in the chapter on climate in "Mann's Colony of Natal," pp. 47 and 69. It is much to be desired that similar papers were procurable, giving a scientific account of the climate of the other natural divisions of South Africa.

Much information on the climate and meteorology of South Africa will be found in Silver's "South Africa," 3rd edition, pp. 195 and 215 to 357 (Basutoland); for Natal, pp. 411 and 416, for Orange Free State and Bloemfontein, p. 457; also in the Cape Directory for 1880, p. 51 and p. 444 (on Natal), and p. 474 (on Transvaal); also in the "Emigrant's Guide," p. 79.

The paper referred to in the following extract from the *Colonies and India* for December 11th, 1880, will probably be found to contain much that is needed in drawing up a good sketch of the climate of the Cape Colony:—

"THE RAINFALL IN SOUTH AFRICA.—At the opening meeting of the present session of the Meteorological Society, held on the 17th ult., at the Institution of Civil

\* But there are so many variations in different provinces as regards all that relates to climate and meteorology that no general sketch can do justice to the subjects.

CLIMATE OF WEATHER CHARTS FROM DECEMBER, 1876, TO DECEMBER, 1877.—GRAHAMSTOWN, SOUTH AFRICA.  
HEIGHT ABOVE THE SEA LEVEL ABOUT 1,790 FEET.

Z.	THERMOMETER.								BAROMETER.			RAINFALL.	REMARKS.

Engineers—Mr. G. J. Symons, F.R.S., president, in the chair—a paper was read by Mr. John G. Gamble, F.M.S., on "The Rainfall in South Africa." The author gives the monthly totals of rainfall from 103 stations for the thirteen months, December, 1878, to December, 1879, and also the monthly means from all stations in South Africa from which a record of five years or upwards could be obtained. It is shown that the Cape Peninsula, the South-West, and the West Coast have winter rains with a dry summer, characteristics of what is called the sub-tropical region, the rains coming with the north wind or anti-trade; while Natal, Natal North, and, in a less degree, Queenstown, have the tropical features of a wet summer and a dry winter. On the South Coast the rainfall appears to be more equally distributed throughout the year, though there seems to be an October maximum at Port Elizabeth and Uitenhage. In the Central and Northern Karoo the maximum of the very scanty rainfall occurs in February and March. These rains generally fall in thunderstorms, each storm seems to come from a westerly direction; but it is a more or less well ascertained fact that these rains do not fall up country until the south-easters have set it on the south and south-west coasts. In the south-east of the colony the transition towards tropical features may be noticed, both Grahamstown and King Williamstown showing a winter minimum in June."

Writing from 2, Garville-avenue, Rathgar, Dublin, December 15th, 1880. Mr. Charles G. Napier, who paid much attention to the meteorology of Grahamstown, says:—

"I send you enclosed the abstract of the weather charts for Grahamstown, 1878; you will see on comparison that they do not very much differ from those for 1877. I have also a slip out from one of the Grahamstown papers, by which it appears there fell there in 1875 21.60 inches of rain, and in 1876, 26.81 inches of rain.

"P.S.—The weather charts for 1878 were kept by Mr. Felix Cornual, formerly my clerk. I think he is still in Grahamstown, and has more information on the subject, as also have I. They kept, and I believe still keep, weather charts in the Albany Hospital, Grahamstown. Mr. John E. Davis, the superintendent, used to keep them."

## APPENDIX B.

### PUBLIC INCOME AND EXPENDITURE.

As regards the Cape Colony and Natal, it is difficult to condense the abundant information contained in Blue-books better than is done in the Directories for each colony, referred to in the lecture.

The following information regarding the Transvaal has not, I believe, as yet, been published in the country:—

### TRANSVAAL FINANCES.

The annexed extracts from the Transvaal Government Gazette, of the 6th December, give the latest information regarding the financial position of that territory, as contained in the financial statement for 1880-1, laid before the House of Assembly, Pretoria, on the 30th November, 1880, by Mr. C. E. Stafford Steele, Financial Commissioner and Acting Colonial Secretary. It will be seen that from £70,000, which was considered a high estimate, after the annexation, the revenues have risen to £160,000, chiefly owing to the better realization of the old taxes. No new taxes have been imposed. Some objectionable imposts, such as the war tax, have been remitted, and something has been done to reduce debt.

### EXTRACTS.

"The revenue estimated for 1880 was £159,658, and the expenditure £153,751, leaving an anticipated surplus of £5,907. The amounts for next year are £172,300 and £164,234 respectively, which would give a surplus of £8,066.

"Turning to the statement for revenue it will be found that the total for the year 1879 was but £93,466, whereas during only three quarters of the current year £133,394 have been received into the Treasury against the twelve months' estimate of £159,658. The expenditure statement shows that £108,574 have been spent up to the end of September against the year's sanctioned expenditure of £153,751.

"Taking the income and disbursements of the nine months ending September, as compared with the three quarters of the sums provided for on the estimates, an increase of revenue will be found amounting to £13,441 and a decrease of expenditure of £6,740.

"Whether the results on the expiration of the remaining quarter of the year will prove proportionately a

favourable as the foregoing is a question which, in a measure, depends on the outcome of the visit of the honourable the Secretary for Native Affairs to the districts of Waterberg and Zoutpansberg. The collection of the native hut tax was undertaken at a late date, and a large amount would seem to be still due from the natives in those portions of the Province specified. Should, however, the collections this year be short of the sum estimated, I have every hope that our finances will, nevertheless, be found to have attained fair equilibrium. The forecasts under other heads have proved to have been so moderate, that unless any extraordinary liabilities be incurred during the remaining portion of the year, I think we may be fairly assured of such a result.

"Political questions have, no doubt, in a measure affected the revenue. The whole of one district (Bloemhof) and portions of two others (Marico and Potchefstroom) fall within what is known as the Keate Award Line, and pending the final settlement of the matters at issue, the payment of taxes has not been enforced within those areas. It is not surprising, therefore, that the Government dues, paid in the Bloemhof district, do not exceed £260.

"Then, again, the Boer agitators are responsible for some portion of the revenue not finding its way into the Treasury. Besides those who refrain from paying, in order to mark their hostility to the Government, there are many who would willingly pay, but do not merely from a lack of moral courage. These latter fear to come forward, but yield to their terror of the opinions of the more violent members of their community.

"I have still to show why a larger sum is anticipated for collection under quitrent in 1881 than that estimated for in 1880, more especially as it has just been proved that only a little more than half the estimated receipts for 1880 were collected from this source. In respect of this I would state that the returns of the Landdrosts were set aside as not being sufficiently trustworthy, and that, in framing this estimate, the conclusions arrived at have been based on statistics regarding landed properties obtained from the office of the Registrar of Deeds. The information so acquired can, I think, be accepted as reliable.

"A few remarks are necessary regarding the railway tax. The receipts during 1880 from this source (both current and arrear) up to the end of September came to £18,500. The amount collected during the whole of 1879 was but £9,496.

"In the early part of this year it was ascertained that the present rate was unnecessarily high for the attainment of the special object for which this tax was imposed. Its reduction was, therefore, determined upon, and a Bill providing for this has recently passed through its third reading in this House. It may be as well to point out that Government cannot afford to remit taxation, and the reduction would not have been made had Government felt itself justified in applying the proceeds of this tax to other purposes than those for which it was created. The charges against the proceeds of the railway tax have hitherto been swollen by survey expenses, payment of claims on material lying in Holland, law charges, and by other miscellaneous items of expenditure connected with Mr. Burgers' scheme, which are not likely to be incurred again. There is every reason to believe, therefore, that, for the future, it will be possible to devote the receipts from this tax solely to the payment of the interest on the debt, and to the liquidation of the principal. For this purpose £7,000 are required annually, and this represents the sum for collection placed on the estimates for the coming year. I should mention that the new law will provide for a possible income of about £8,000. There are, moreover, large outstanding balances still due under this head of revenue, as also the value of material sold, to credit to the railway account.

"With regard to the native hut tax, the amount to

be derived from this branch of the revenue continues to be a subject of speculation. The collections were not undertaken much before the month of May, and by the end of September, £13,225 had been paid into the Treasury, a further sum of £7,000 being in transit at the time. The Hon. the Secretary for Native Affairs is personally superintending the working of the law. The three most populous districts have yet to contribute their quota to the revenue; it is possible, therefore, that the anticipations in respect of this tax may yet be realised before the end of the year. It has to be borne in mind, however, that the officials entrusted with the duty of levying this tax are new to the work, and, moreover, that their knowledge of the country has been necessarily limited, owing to the native disturbances, now happily at an end. This ignorance of the country is no doubt taken advantage of, and many evade paying who will not so easily escape next year, when the native commissioners and others become better acquainted with the nature and scope of their duties. Thus, in the absence of any apprehension as to the soundness of the estimate framed for the current year, viz., £35,000, it has been considered safe to place an additional £5,000 to this sum for the estimates of 1881.

"Duties generally are expected to yield a much larger revenue to that hitherto obtained. In 1879, the duties (inclusive of import) came to £51,632. For 1880, they were estimated at £53,103, but at the end of last quarter they had already reached the sum of £57,922.

The amount placed on the estimates for next year is £71,670.

"The principal heads under which such a large increase is anticipated are import duty, transfer dues, licenses and revenue stamps.

"On referring to the revenue statements placed on the table, it will be seen that from import duty an increase is expected of £3,850, as compared with the sum estimated for 1880. In 1879, £19,252 were received; during nine months of this year a sum of £17,791 was collected, and for 1881, £22,120 have been placed on the estimates. The unsatisfactory working, and also the somewhat unfair incidence of this tax has not been lost sight of. It is hoped that the approaching settlement of the Keate Award question will enable Government to adopt measures for the prevention and detection of what may be termed the smuggling which, there is ample evidence to prove, is carried on in the south-western districts. The steps to be taken for the better application of the law in other districts is a matter which is at the present moment under the consideration of Government. Fewer evasions of the law are expected, and it is anticipated that the continued prosperity of the country will fully justify this forecast made of the receipts from 'customs.'

"Coming now to 'Duties other than Import,' the chief items calling for remark are transfer dues, licenses and revenue stamps.

"First, to take transfer dues:—

"The estimated amount for the current year is £10,000; the receipts up to the end of September exceeded, however, that sum by £2,280. For 1881, £16,000 have been placed on the estimates. The expectations in respect of this increase are based on more extensive sales of land being anticipated, and on the coming into operation of the new law—XI, 1880. Under the provisions of this law, it is competent for the Receiver of Transfer Duty to cause a valuation of property to be made when the price under which it is alleged to change hands appears inadequate.

"*Licenses.*—In 1879, £8,786 were received under this head. For the current year, £9,125 were estimated; the receipts are about £1,400 in excess of this already. For 1881, £12,000 have been placed on the estimates, and there is every reason to believe this sum will be realised.

"*Revenue Stamps.*—The extension of the principle of

collecting certain items of revenue by means of stamps has been attended by beneficial results. In 1879, a sum of £13,457 was collected in this form; during nine months of this year £13,747 were collected. The somewhat large increase for 1881 is anticipated partly on the grounds stated in connection with transfer dues, and partly in consequence of measures having been introduced in this House providing for fees being levied in certain cases, notably under the Insolvency Law.

"Under 'other receipts' are comprised certain items which amounted, in 1879, to £7,501. During the three-quarters of the current year they amounted to £10,834. A sum of £9,250 has been estimated for 1881. The excess, during 1880, as compared with the figures for 1879, is due partly to increase sales of Government property, and partly to the fact that the receipts of the Telegraph Department are included under this main head. The line having been opened only during the latter part of last year, the receipts for 1880 are naturally considerably greater than those for 1879. Proportionately, however, the receipts do not compare favourably, and there would appear to be a falling off in the work which is not confined to a reduction in the number of Government messages. The revenue from this department, for 1881, has, consequently, been estimated at a sum representing nearly the receipts of the current year.

"The total revenue to be derived under all sources, during 1881, has thus been shown at £172,300, from which an estimated expenditure of £164,234 1s. 6d. has to be met.

"On referring to the statement, it will be found that the disbursements for 1881 are expected to exceed those of the year now drawing to a close by £10,482. According to the analysis of the expenditure given in the statement, there is an excess in the cost of establishments of £14,436. This large excess is, however, not real, as I will proceed to explain. It will be noticed that the classification of the expenditure for 1881 differs materially from that adopted in last year's printed estimates. This modification in the form of the estimates has been followed in accordance with the wishes of the Right Honourable the Secretary of State, conveyed by his despatch No. 33 of June last. In the carrying out of these changes, large amounts, formerly appearing under the separate heads of aborigines, colonial defence, forests, &c., are now embodied under 'Establishments.' The charges appearing under those heads in this year's estimates represent solely expenditure on services exclusive of establishments. A no less sum than £10,800 of the apparent increase is simply due to this alteration in the mode of classification. To the revision of establishments, and of the rates of salary, an increase accrues on last year's estimates of £3,600. This sum is arrived at after deducting the saving effected in certain departments consequent on such revision.

"This scheme, to which the Secretary of State has notified his approval, allows of a permanent increase in salary to ten officers of the Government, and it further provides for additions on the incremental principle to the salaries of twenty-two other officers.

"The sums expended in 1879 on pensions and grants amounted to £1,673 11s. 11d.; for the current year, an expenditure under this head of £1,430 was estimated for; the amount entered for 1881, is £2,150, of which £1,650 only is foreseen. The following are the names of recipients of pensions, now appearing on the estimates for the first time:—Sir Theophilus Shepstone (late Administrator); P. J. van Staden (late Landdrost); Mrs. Hamilton (widow of Captain Hamilton); and Captain Beeton.

"Colonial Defence.—The apparent decrease in expenditure under this head, as compared with the actuals for the current year, is not real. The charges on account of colonial defence during the coming year will be far in excess of those which the Province has hitherto been

called upon to meet. Under the head of 'Establishments,' it will be found that an outlay of £6,805 has been provided, on account of a force consisting of (73) seventy-three mounted men (officers included) and of (186) one hundred and eighty-six foot police. The amount shown under 'Colonial Defence' in the statement represents the cost of ration, equipment, &c., and the value of the contribution payable to the Imperial Government for the maintenance of the mounted infantry. The scheme for which provision was made on the estimates for 1880 was purely a tentative one.

"Public Works.—Under this head a sum of £9,810 appears on the estimates for 1880, of which only about one-half was expended up to September. I should state, however, that over £7,000 has been spent to date, and that the Surveyor-General reports work on hand on which a further outlay is involved of £2,500. In connection with these works, material of the value of about £500 has been used which does not show in the accounts. This sum represents the value of material prepared for building purposes by convicts.

"As it is a somewhat common complaint that, although the public are called upon to pay road-tax, the roads are rarely repaired, I would mention that the receipts from road-tax (current and arrear) during the three quarters of this year were but £627, whereas the expenditure on roads and bridges is expected to reach the sum of £1,400, of which £800 have already been spent.

"The necessity for public works on a large scale being undertaken is fully recognised; the current revenue could not, however, stand the additional strain which would be brought to bear on it by any extraordinary works being taken in hand. The reduction of the expenditure below the limit exhibited in these estimates does not seem feasible; special measures will therefore have to be taken to admit of works on a large scale being carried out. Whether it would be desirable to add to the burdens of the Province by borrowing capital for the construction of unproductive works is a matter which, I think, is open to question. It is certainly true that the annual rent for Government buildings in Pretoria alone represents a capital of £15,500, raised at 6 per cent. But I am afraid we should not obtain the accommodation we now have by expending that sum on new buildings.

"As regards the present debt of the Province, and judging by the charges annually payable on it, we find that in 1880 (1-7th) one-seventh of the revenue was devoted to meet the charges payable on account of interest, and in part liquidation of the principal. For 1881, the charge will be about (2-15ths) two-fifteenths of the estimated revenue, or about 2s. 7d. in the £; the fact must, however, be carefully borne in mind that the present debt is not a perpetual charge on the revenue, for, as will be seen from the statement which has been placed on the table, the principal is gradually becoming reduced. As an instance I would point out that of the two funded debts one (£63,000) should be extinct in 1893, and the other (£93,833) in 1902.

"Lest in making these remarks I be misunderstood, I would at once state that there is ample evidence of a marked financial improvement having set in, and I think we may depend upon even greater progress in the future. In support of this I would mention that whereas our overdraft, both at the Crown agents and at the Standard Bank, amounted on the 1st January to £163,496; at the present moment it is only £140,900. In reference to this improvement I notice in the leader of this morning's *Argus*, the following statement:—

"But when it is considered that the process of astringing has been very freely resorted to, the better balance-sheet shown by this Government can scarcely be regarded as representing the free and willing payment of taxes. In the majority of cases the debtors at all events wait until the demand has been made, and not a few refuse to pay until actually summoned before the Law Courts."

in regard to this, I am happy to be in a position that our balances have not been materially by the action of the Courts. In September requested the Landdrosts to report what portion of the revenue received by them had been paid issue of notices, how much after summonses, much through subsequent legal proceedings been taken. From their replies I find that a sum than £18,200 was paid on intimation of the fine being received by the parties, £1,500 on fees being issued, and £500 only on subsequent the Lower Courts.

this it may be inferred the 'process of squeez-

ing has been applied, perhaps, more in revenue officials than to revenue defaulters. Had the revenue officers been passed to do their duty, or had they been accorded greater facilities in the performance of it, in years gone by, it would not have fallen to the lot of this Government to collect the arrear taxes due to the late Republic. That there are many who adopt the *role* mentioned in the *Argus* is unfortunately a fact, but the present balances, as I have already stated, have not been materially affected by the attitude they have assumed, the conclusion to be drawn being that but for such action the improvement in the balances would have been even still more marked."

### APPENDIX C.

#### THE CAPE OF GOOD HOPE, NATAL, AND ORANGE FREE STATE.

The following brief statement of facts will illustrate the growth of the Cape Colony during the past sixty years—

#### GROWTH OF CAPE COLONY.

—Area, 128,000 square miles; population—18,000; Hottentots, 29,000; slaves or apprentices, total population, 110,000.

—Imports, 454,166; exports, £150,900; included, £32,170; public revenue, £109,000; public stores, £53,000.

—Total population of eastern districts only,

1830 to 1834.—Imports (in eastern districts only), £134,119; exports, £207,282.

1845 to 1849.—Imports (in eastern districts only), £1,356,000; exports, £1,017,391.

1850.—Total population of eastern districts only, 170,000.

1855.—Imports, £1,588,000; exports, £1,327,000 (exclusive of diamonds); public revenue, £348,000.

1865.—Population, 496,300.

1866.—Exports, £2,590,000 (exclusive of diamonds); public revenue, £732,000.

1875.—Population, 720,900, composed as follows:—Europeans, 236,783; Kaffirs and Bushmen, 314,133; Hottentots, 98,561; mixed races, 87,184; Fingoes, 73,506; Malays, 10,817; total, 720,984.

1876.—Exports, £4,499,000 (exclusive of diamonds); public revenue, £1,864,000.

PRINCIPAL IMPORTS AT DURBAN FROM OFFICIAL RETURNS.—COLONIAL GOVERNMENT VALUATIONS.

1820.—Currency, depreciated paper; churches out of Cape Town, 3; education, much neglected; *Government Gazette*, and an advertising sheet, only periodicals publications.

1824.—Press statistics—7th January, Messrs J. Fairbairn and Thomas Pringle (*The Post*), published in Cape Town, the first number of the *South African Commercial Advertiser*, May 17th, publication interdicted by Lord Charles Somerset.

1827-8.—Royal Commission sent out in 1824, recommended in Report, dated 6th September, 1826, freedom of Press; establishment of Supreme Court, under Royal Charter of Justice; substitution of Civil Commissioners, Resident Magistrates, and Justices of the Peace, for Boards of Landdrost and Heuraden; abolition of "Pacht" (Government monopoly of sale of wines and spirits) of office of Vendor-Master (Government Auctioneer), and Burgher Senate.

1829 to 1839.—South African College founded in 1829. Sir J. Herschel arrived 16th January, 1834, and submitted an education scheme to Government in 1839. Dr. Innes, first Superintendent General of Education. 20th May, 1835, King William's Town founded. Abolition of slavery, proclaimed in 1834, came into effect at the end of four years' apprenticeship, in 1838.

1836—Six thousand Dutch colonists followed Field Cornet Piet Retief, when he "trekked" from the colony. 1840 to 1850.—Road-making commenced by Mr. John Montagu, Colonial Secretary. Public road Board, established 1844. Territory of Natal annexed to Cape of Good Hope, 31st March, 1844. 29th July, 1848, Battle of Boomplaats, declaration of British Sovereignty over Orange Free State, and consequent founding of Transvaal republic by defeated emigrant Boers.

1851 to 1861.—1853, 21st April—Orders in Council granting representative constitution. First Parliament, 1854. Orange Free State made independent, 1854. First sod of Wellington Railway turned by Sir George Grey, 31st March, 1859. Railway finished, 1863. First truckful of stone for Cape Town breakwater tilted by H.R.H. the Duke of Edinburgh, 17th September, 1860. First stone of docks laid by H.R.H., 25th August, 1867. First line of electric telegraph completed to Simon's Farm, 1860. Public library and museum founded by Sir George Grey.

1862 to 1879.—First diamond discovered, 1867. Responsible Government established, 1872. University of Cape of Good Hope incorporated, 1873. Griqualand West annexed, 1877-80. Submarine cable, 1880.

1865.—Education—Schools, 360; scholars, 30,335; State expenditure, £23,027; local expenditure, £19,396; area of holdings in Colony (morgen of two acres each), 20,464,000; area of land under cultivation (morgen), 217,692; wool produced, 18,905,000 lbs.; mohair, no return; live stock (woolled sheep), 8,370,000; draught cattle, 249,000; other cattle, 443,000.

1875.—Education—Schools, 641; scholars, 64,167; State expenditure, £38,753; local expenditure, £43,596; area of holding in Colony (in morgen—two acres), 39,947,000; area of land under cultivation (in morgen), 274,413; wool produced, 28,316,000 lbs.; mohair, 138,128 lbs.; live stock (woolled sheep), 9,986,000; draught cattle, 421,000; other cattle, 689,000.

1879.—Education—Schools, 843; scholars, 66,000; State expenditure, £70,000; local expenditure, £81,000.

The following statistics of three districts in the Orange Free State, are taken from the *Cape Times*, of the 10th November last:—

"The *Friend of the Free State* gives the following statistics:—'The total population of the district of Bloemfontein, Winburg, and Cronstadt is, respectively, 13,274, 15,858, and 14,177—the first named district, however, possessing the largest number of white inhabitants. The number of woolled sheep in the said three districts is, respectively, 840,031, 582,390, and 478,160. The entire area of the district of Bloemfontein

is 1,139,165 morgen, of which 1,894 are en Winburg, 1,337,340, of which 3,878 are en Cronstadt, 1,622,300, of which 6,649 are en Cronstadt is consequently the largest district three, and Bloemfontein the smallest. Bloemfontein possesses the most horses and woolen sheep, Winburg the most horned cattle and big-tailed sheep, and Cronstadt the other two districts in the number of annually produces.'"

## APPENDIX D.

### DIAMOND CUTTING IN CLERKENWELL.

In connection with the industries that are affected by the discovery and importation of diamonds, the recently established lapidary Messrs. W. Ford and Co., of Clerkenwell, draw notice. A full and detailed account of their enterprise appeared lately in the "Watchmaker, and Silversmiths' Trade Journal."

About a century and a half back, London chief seat of the diamond-cutting business circumstances caused this industry to be removed to Amsterdam, and this city till very lately had a monopoly of this trade. To the untiring efforts of Mr. W. Ford is due the revival of this industry in England. About seven or eight years ago he was a lapidary in Red Lion-street, first turned his attention to the cutting and polishing of diamonds. Great perseverance was necessary, because people naturally reluctant to entrust valuable crystals to the least unskilled handling. This prejudice was, however, gradually overcome, as Mr. Ford's skill was well shown that the diamond cutter's art was not in possession of the Dutch. Although at first dependent on Dutch workmen, they are now superseded by Englishmen, to the great satisfaction of the firm. It is to be regretted that some of the Dutch cutters emulate the jealousy of their Dutch brethren and try to keep their experiences to themselves. Such is, however, the case; so that Mr. Ford is obliged to separate men and apprentices, and take the latter under his own supervision.

In 1874, some of Mr. Ford's employees carried off prizes offered by the Turners' Company for their daries' work. Mr. Vincent Albertoldi secured prize for his remarkable fine shell and carbuncle, and Mr. Henry Gilce Spencer the prize for carved onyx shell, bow and flower of green. Their exhibits were bought by Mr. Hunt and Tennant, two of the judges for the lapidary mark gratifying alike to the artists and their employers. In class D (diamonds), Mr. John Parsons and Mr. Watts, also employed in this factory, took the third prizes respectively. In 1876, Mr. Charles ton, Mr. George Brown, and Mr. Thomas Jackson again successful competitors for prizes offered by the same company, all employees of this establishment.

Extract from the "South African" for Nov. 11.

### THE DIAMOND FIELDS OF GRICUALAND WEST. R. W. MURRAY.

The South African Diamond Fields are on the greatest, if not the greatest, wonders of modern times. The discovery of diamonds on the banks of the Orange River, in 1868 and 1869, attracted thousands of people to that part of Griqualand West, and to the extent in 1870 of the Hebron, Pniel, and Barings, and afterwards to such other river diggings as Waldek's Plant, Cawood's Hope, &c., &c. Up to the end of 1870 it had been concluded that the deposits were only to be looked for on the banks

\* A paper by Mr. T. W. Tobin, "Notes from a Diamond digger in South Africa," is published in the *Journal*, p. 304.

but before 1870 had closed, it became known that ds had been found at Du Toits' Pan without g out the diamondiferous soil, which was, during ly time of the river diggings, a most laborious n. The river diggings was then almost abandon- and diamond-searching was carried on for a long t Du Toits' Pan on the dry-sorting system.

In the year 1871, it was ascertained that there were ds in the Kopjes of Old de Beers and Bultfontein, July of that year the Colesberg Kopje (now the ley Mine) was rushed, and the whole of the four mentioned diggings were for a long time worked dry sorting system, and the *debris* thrown to- in heaps outside the diggings and abandoned. However, the diggers found that the abandoned contained almost as many diamonds as they had ut of the diamondiferous soil whilst it was in sands, and that it would be ruinous to continue r-sorting system, as one-half of the diamonds be lost to them, unless the soil, when taken out of ms was thoroughly saturated and washed out ater, as they had been accustomed to wash it out lligging on the river banks. When the Kimberley and the Vooruitzicht estate, on which the Kim- Mine is situated, were purchased from Messrs. and Co., the proprietors, by the Government, 0 was offered for the abandoned *debris* surround- at mine alone, which offer was refused.

The diggers having ascertained that water was the essential to successful diamond-searching, and the ter of working claims having changed, at least ars since, from diamond-digging to mining for ids, new and more effective appliances than the used at the river were invented, and wells were It was also ascertained, when the light surface as passed, that the richer diamondiferous strata a rocky nature, and that this must be thoroughly ted with water, and exposed to the sun, before it be sufficiently crumbled for washing out in the machine; and, from the time that strata has been amond-yielding material, the demand for water n immense, and far greater than the supply.

In the last six years, at Kimberley, Old de Beers, oits' Pan, and Bultfontein, diamond-mining has a permanently settled industry, as is coal-mining ewcastle, copper-mining in Cornwall, or tin- g in Devon. It was estimated long since that was invested in claims, plant, and steam nery, in the beforementioned four mining centres, twelve millions sterling (£12,000,000), and Messrs. r, Ransome, and Sims, and other engine and ne manufacturers, are sending out first-class es and machinery by mail steamers, and are never ut orders in course of execution. There are no ments so much sought after as those which the nd-fields offer, and the value of claims has sed more during the last year than in any other d of the existence of the diamond-fields.

The claimholders consider that when the Kimberley r Company shall have made the water supply ent and regular, their returns will be so much as to greatly add to the value of their claim rties, which they, since the last Act of the Griqua- West Legislature, hold on fixed property titles, d of on monthly license as heretofore.

no reason does the present water supply approach and for mining operations and town consump-

The rainfalls are confined to but a few months of ar only, and, subject as the country is to periodical ts (which, during the ten years of the diamond have covered half the period of their existence), lls dry up, and mining operations are occasionally t to a standstill.

In the Vaal River only can a sufficient supply of for miners and householders be obtained. Water e had by the miners at whatever price is demanded ll proprietors, as the suspension of mining opera-

tions is utter ruin. The claimholders, by such suspen- sion, would lose all their native labour, and when once the natives are thrown out of employ, they leave for their homes, many of which are from 1,000 to 1,200 miles distant. The costly establishments must be kept up, license money must be paid to Government, and rates to the mining boards, whether the claims are worked or not, and all this in addition to the loss on dormant capital invested, which is very great, seeing that many of the claims of 30 feet by 30 are of the value of from £5,000 to £10,000 each.

Water has for years never been obtainable for less than 2s. 6d. for about 100 gallons, and in times of drought it averages 5s.

Since the establishment of the mines, fine, large, permanently settled towns have grown round the mining centres, churches of all denominations, with accommodation equal to those in the older towns, have been built, and others are in course of building. The Customs' duties paid on imported articles of consumption in the fields has been estimated by the Secretary of State for the Colonies to be at least one-third of the whole amount received at the colonial ports; over one million and a-half is paid for land carriage from the port towns to the fields; the trade done in Kimberley, Du Toits' Pan, Old de Beers, and Bultfontein is larger and more brisk than in any towns of the same size in South Africa, and four banks have been established, and they do a very large and lucrative business.

During the last seven years the mines have afforded employment to 650,000 natives, at an average wage, in money and kind, of 22s. per week. There are never less than 16,000 natives at work in the mines in addition to white labour, and the annual municipal revenue administered by the Town Council, chiefly obtainable by a rate of 3d. in the £ on the value of house property, is upwards of £25,000.

That the diamond mines are destined to be permanently the greatest wealth-producing power of the country, has been ascertained by experiments of various kinds; and the shafting which has taken place proves that depth does not abate the yield of diamonds; and that the deeper the digging the better the quality, as those who have had experience in the Kimberley and other mines can affirm. The building trade flourishes more and more every year, as stores and residences are now built of brick and stone, and the great proportion of merchants, traders, and mechanics have made their homes, and settled down with their families, in the towns.

Sir Bartle Frere, at a banquet given in his honour at Kimberley this year, in speaking of the great progress, wealth, and importance of that place, said:—"Even if diamonds failed to-morrow, which they certainly will not do, Kimberley will always be a large, wealthy, and important town, it being the centre of the great interior trade of South Africa."

Since that time the London and South African Exploration Company have laid out a new town of great size on the Kimberley side of Du Toits' Pan, and not only has every building site been taken up, but already handsome stores and residences of brick and stone are in course of erection there, whilst Bultfontein has extended itself up to the boundaries of Du Toits' Pan.

The diamond fields are now part and parcel of the Cape Colony, which as the returns of the Crown agents show, is one of the wealthiest and most progressive of all her Majesty's colonial dependencies, and the 4½ per cent. debentures recently issued for the annexation of Griqualand West to the Colony were placed at £102 to £103.

London, Nov., 1880.

## APPENDIX E.

### OSTRICH FARMING.

The following sound remarks on ostrich farming are from a late number of the "Squire":—

"I don't think ostrich farming may be fairly said to date further back than the year 1865. I know that when I arrived in the colony, in 1863, such a thing was unheard of, indeed it was not until 1870-1-2 that any appreciable advance was made.

"The ostrich (*struthio camelus*), as Macaulay's "every schoolboy knows," is a bird of the desert, its habitat the boundless, mirage-distorted, sun-scorched, dreary Karoo. So extensive are his feeding grounds and rapid his movements that fifty or sixty miles are often travelled by him, in a wild state, between daybreak and dark.

"How, then, were the subjugation and domestication of this lord of the desert achieved? For the most part by securing the chickens when very young, or else by procuring the eggs, and hatching by artificial incubation, so that in a very few years in the place of tens as many thousands might be counted in both provinces, east and west. Indeed, so rapidly did they increase, that great fears were entertained by many that overproduction, and consequent depreciation in value, would be the ruinous issue. But this was not to be. Nature in this, as in many other instances, apparently demands a penalty for domestication. Her laws being violated, and made subordinate to artificial methods, produced diseases of various kinds. I have known instances of whole broods dying off suddenly, without any apparent cause, in spite of every care, attention, and treatment. Numbers die from exposure to cold and wet—from broken legs, intestinal entozoa, stoppages in the intestines, diseased liver, and various other causes. If not in a sound, healthy state, a cold rain is almost sure to prove fatal. As an instance, I once had a flock of nine-months-old birds exposed to a rain of two days' duration. They got so thoroughly saturated, exhausted, and chilled, that they could not be brought home to a place of shelter. Even after the weather had cleared up, one of the poorest-conditioned was so completely numbed that he could not be induced to walk a step, and had to be carried home in front of a man on horseback, wrapped in a wool bag. In this plight, almost lifeless, he was placed before a briar fire, and a pint of warm gruel, with about half a tumbler of brandy, was administered to him. This, repeated at intervals of about twelve hours, entirely restored him, and I had the satisfaction of selling him some few months after for £25.

"A man to start ostrich farming fairly should have at least £1,500 capital. He would, in the first place, have to hire a good farm, say of 4,000 acres. This seems at first sight, especially to an inexperienced person, unnecessarily large. In good seasons, of course, it would be, but then one must reserve for times of drought and scarcity. For this farm, unenclosed—there being very few enclosed farms in the colony—he would have to pay a rental of about £150 per annum. To stock it he would require to purchase at least 100 young birds, at say £10 a piece—total £1,000. For £400 he could purchase three pairs of good breeding birds. These he would have to put in separate enclosures, or paddocks, of say ten acres in extent. Wire would be the cheapest fencing, drawn very taut, and wattled through from top to bottom with bush, as birds are liable to kick through and hook their legs fast, and often break them. And here let me add, a broken legged bird never recovers. The best and most humane way is to knock the ostrich on the head at once. You may bind and splinter the broken bone, but it doesn't help. He kicks, and struggles, and worries in his efforts to rise, that it makes the healing or uniting of the broken member a matter of impossibility. It is not unusual for birds, when playing or waltzing—which they do in the most graceful manner, whirling round on tip-toe with expanded wings—to drop down as if shot. You go up surprised to see what is the matter, and find a broken leg, snapped like a carrot.

"To return to the question of expenditure. We have supposed it to cost about £1,400 to stock the farm with birds. We have still £100 remaining. This would be

required for purchasing wire, poles, implement &c. The first year's increase of three pairs of young birds would be about two broods each, of 5 a brood. This is a low calculation. I have a pair to bring out as many as four broods in a year but they were exceptionally good. Thus for every pair he would get sixty chickens. Their value average about £10 each, so we have here 600 chickens alone. The first crop of feathers from 100 young birds, at an average of £1 per bird, would give a total of first year's produce £700. Plucking two years and upwards yielded, when I left the colony in April last, an average of about £8 per bird. The feathers are plucked, or rather cut, three times a year or once every eight months. This is a simple process. The birds are driven into a small enclosure or yard, and packed so closely as not to admit of room for shifting about. Then you take a clipper and cut the feathers with one hand, and cut with the other. The blacks, drabs, and tail feathers are always cut, only the wing feathers are cut. In two months the points or stumps are drawn; they, being tanned and ripe, come out with ease.

"The ostrich feather is characterised by its quill exactly in the centre of the feather, the other birds it is a little on one side, causing it to be of unequal width. The ostrich feather, arising doubtless from their being tapered shafts and delicate gossamer webs, to their being valued highly as articles of ornament for all ages. The Egyptians are supposed to have used them as a symbol of justice, from the fact that the webs being equally balanced on each side of the shaft. In old paintings of Rembrandt and Vandyke, ostrich feathers hold a prominent place as ornaments in the hats of the bucks and bloated time.

"Ladies do not seem to have taken to them comparatively modern date. Now they have become fashionable, the deep-seated harassing dreariness of the ostrich farmer is that they will be too common, and therefore be disused by the classes. But I think there is little fear of this, as first-rate feathers will always maintain a price high enough to preclude the possibility of their coming into general use.

"A very important desideratum is the obtaining of a good farm. Some farms are almost entirely useless for ostrich farming, being destitute of the requisites, such as salt bushes (*brak*), succulents &c. An inexperienced person must on no account trust to his own judgment, or his vanity, but be almost sure to end in disappointment and loss. He has no friends in the colony, he should of course have introductions, either at Cape Town or Port Elizabeth, to some well-known breeder of respectability and skill. In a future article I shall endeavour to give an account of the habits and ways of the ostrich in domestication, and on the method of hatching, and rearing the young.—ALFRED EVANS."

#### VINE CULTURE.

The cultivation of vineyards was one of the industries established by Europeans in South Africa. The Dutch settlers soon found the climate at their new home favourable for the growth of vines, and almost every settler had a patch of vines attached to his holding. But the more general and better treatment derived from the French emigrants, who at once turned themselves down to this special cultivation; however, the eminently conservative habits of the Dutch overcame the greater enthusiasm of their French neighbours; at all events, certain habits were acquired

\* A paper on the "Progress and Prospects of Ostrich Farming in the Cape Colony," by Mr. P. L. Simmonds, in the *Society's Journal*, vol. xxiv., p. 223.

red, and a treatment of vineyards was followed, which because it was good and suitable, as because the custom. This has continued pretty much, but rare exceptions, to the present day, and a source is generally adopted irrespective of the of species, of soil, of aspect, of drainage, or their essential factor. Wines thus produced a certain fixed character, and it is not so that the European cultivator has advanced, as Cape farmer has stood still, that has operated an improvement in the character of Cape wines. There, however, been other evil influences at work. The merchants adopted the practice of giving a reduced price for wines each season, and the man the least trouble, and by any means, produced got the same price as one who had expended more care. Thus, the only consideration soon became. Farmers took to planting their vines in the valleys, and, not content with the natural and swamps, actually, in many cases, led water through their vineyards; the result need not be said on. The wine merchants having, as thus reduced the price of wine at the beginning of the season, ought from anyone as far as their means permitted, emptied all their purchases into large, what is called "stuckvats," holding from 800 to 1,000.

Before this, however, the farmer had supplied the natural fermentation by large admixture of spirit, and made, and from which there had been no of extracting the fusil oil. The wine now on the hands of the wine merchant was mercilessly made, more spirit and compounds were introduced, and raw wines delivered in April, May, and June, sufficiently "prepared" by the wine merchant to be sold as matured wines by about November and December. What result as to quality need hardly be said. There was a great encouragement to the manufacture of wine as arose from the protective Customs duties in the colony, all foreign wines paying 5s. 6d. per gallon, while local made wines only 2s. 9d.; thus, while this lasted, the differential duty admitted a very large portion of Cape wines, the quality of which did not depreciate. No wonder that Cape wines, under such influences, acquired a bad reputation. On the introduction of the English wine duties, the Cape wines, however, and from that time the exports hence were quite insignificant, and are almost confined to a few wines, which, from their excessive sweetness, rather liqueurs than wines. About three years ago, a very energetic attempt was made to improve the quality of Cape wines; some few gentlemen were invited to rally the importance of the most important industry in the western province, and from their knowledge of European viticulture, were persuaded, with a most beautiful climate, a fertile soil, and good vines, only science was necessary to produce good wines. After very great labour and difficulty, they started a company called the South African Wine Growers' Association. Shares in this company were quickly taken up, and the first act of the then Board was to get out an expert from Europe, who was acquainted with wine growing and wine making.

This gentleman was at first coldly received by the farmers, wedded to their old prejudices; but, as they realised the fact that the company would produce wine of quality, and pay an excess over anyone else for wines made on their system, the number of vines planted on the improved principle increased, yet very far from general. The expectations of the promoters of this company are fully realised by the quality of their wines, which, of course, are as yet years old, but they show a promise of quality unknown, and such as must command a large trade, but for the present, the home demand, which is probably as much as they can supply. The prospects of the company are in every way excellent. So much so that the company promises to

be one of the most remunerative and important institutions in South Africa.

The chairman of the Wine Growers' Association (before referred to) having gone through a large part of the French and German vineyards about a year since, partly for the business of the company, was naturally much alarmed at the rapid spread of phylloxera, and made this disease a careful study. On his return to the Cape, he felt with others that it was essential steps should be taken to prevent, if possible, the introduction of this pest to the colony, and very strong representations and petitions were presented to the Government, the result being, that all vines, cuttings, grapes, plants, tubers, and bulbs, were forbidden to be imported; the Government further, on the prayer of the petitions appointed a Commission to ascertain if phylloxera existed in the colony (as had been stated) and further, to report on the diseases really incident to our vines and viticulture generally.

Specimens of vines said to be affected with phylloxera, contrary to the distinct opinion of the Commission, have been sent to England, and submitted to Sir Joseph Hooker and Dr. Corner; unfortunately, the specimens did not arrive in good order, but so far as the before-named gentlemen could discover there was no trace of phylloxera; fresh samples preserved in alcohol are going home immediately for further investigation, but it may safely be affirmed that the disease does not now exist in the colony.

The labour and researches of this Commission promise to be most important, not only showing what diseases now exist, but how the different soils should be treated. Hitherto, a sort of uniformity of plan has been adopted, whether the soil was stiff clay or light calcareous soil; in fact, with but very few exceptions, viticulture here may be said to be half a century behind its condition in Europe. Further, it is the design of the Commission to prepare maps, showing the area occupied in wine farms, the number of plants on each, the soil and the aspect, when on a hill, &c. When this is done, the colony will, for the first time, know the real extent of this industry, at present, calculating on the area already examined, there cannot be much less than 150 millions of vines in the colony, and but a fraction of the land well adapted for this business is yet under that cultivation. For miles, running along one of our main lines of rail from Cape Town, hills ascend on either side, and, probably, no climate or soil in the world is better fitted for the cultivation of vines, and it is no exaggeration to say that there is an area in the colony of the finest soil for vineyards, capable of supplying the whole world, if the devastations in Europe progress. Many people affect to sneer at the Cape wines; but, though it is undoubted they were bad, it is proved that they can be made excellent, and there can be no doubt that further scientific applications will show, as in Europe, continually improving results. It is at first sight somewhat surprising that European capital and talent has not more largely sought this country; but a wine farmer is not a very ready emigrant, time and capital are required, and comparatively few emigrants can afford to wait three or four years, which would be occupied in bringing a vineyard into good bearing. Already, however, pioneers from Europe are beginning to turn their attention to this industry, and provided only we can keep out the phylloxera, viticulture will form as important a source of wealth to this colony as it has proved in France.

## APPENDIX F.

### AGRICULTURE.

*Memo of Information Furnished by Walter Peace, Esq., Emigration Agent for Natal, 21, Finsbury-circus.*

*Coffee.*—Crop in 1870, 960 tons. Quality classed as "Plantation Ceylon," very good. Crop gradually

declined for years after 1870, and is now only again beginning to increase. Reason—Planters got an idea that continually pruning would “help nature;” they “bled the trees to death.” Since the planters have allowed nature to do the work herself, the growing of coffee is beginning to pay again. Instead of using the knife, the planters manure the trees.

*Sugar* has a history in Natal similar to that of most other cane-growing countries. The beginners had neither the practical knowledge requisite, nor the necessary capital. Fifteen years ago Natal planters thought that only flat lands were suitable, now the bulk of the crop is grown on hill lands. The planting season is September to November. The first crop is ready about 21 months after being planted. The cotton crops follow at intervals of from 15 to 18 months; generally at least three crops are taken from the same plants. On some few rich alluvial flats, as many as 10 or 12 crops have been taken without the land being re-planted. First crops on good land, if with ordinary favourable season, and if the weeds be kept down, are calculated to give 2½ tons (5,600 lbs.) per acre, besides treacle, which is afterwards distilled into rum. Succeeding crops, called first rattons, or second rattons, are expected to yield not less than 1½ tons (3,360 lbs.). These figures are below the average experience of planters in good seasons, 3½ tons of sugar per acre for first “plant cane,” having often been obtained. The terms of sale in Durban are prompt cash. The average value, taking the average by shipments, is between 22s. and 23s. per cwt. White crystal sugar realises 28s. to 30s. per cwt. Yellow crystallised, 24s. to 25s. per cwt. Heavy syrup sugar, 17s. to 18s. per cwt. The “Central Mill” system has been at length successfully introduced at the “Usine Centrale” in Victoria county, where growers of cane deliver their crop (by rail or by wagon), and, after the juice is extracted, the value of sugar contained therein is ascertained by testing the density of the juice. The grower can receive his payment for the proportion coming to him (calculated at about two-thirds of the value of the sugar at existing prices) without delay, the manufacturing company making a profit on the cost of manufacture out of the other third. The mill I refer to has cost from about £70,000, I hear, and will turn out 15 to 20 tons of white crystallised sugar per day. A mill capable of making 2 tons of sugar per day can be erected for about from £5,000 to £6,000, including all good buildings. The present crushing season is said to give the largest crop yet produced in the colony, and is estimated at 15,000 tons—worth over £300,000. As with coffee, “the lane seems to have turned,” so with sugar; the losses of the past, which have been very heavy, and from many causes, seem likely to be compensated for in the immediate future, not, though, in many instances, to those who suffered the loss, but to others who have purchased estates which the former owners could not retain. Manuring the land for sugar-cane has only been resorted to as yet in very few instances in Natal.

*Extract from the “Natal Witness,” October 9, 1880.*

#### PIETERMARITZBURG AGRICULTURAL SOCIETY.

One special general meeting and five committee meetings have been held during the year, all of which have been well-attended. The subject of procuring the passing of a Fencing Law was under consideration at one of the above meetings, and a petition for the purpose was framed, after several discussions, and laid before the Legislative Council.

No legislation thereon has yet resulted, the subject being found to be surrounded with many difficulties.

The exhibits of live stock were, on the whole, satisfactory, all the pens erected for cattle, and most of those for sheep, being occupied by well-bred animals,

many of which non-exhibitors were frequently heard coveting the possession of.

The pens of cows and heifers were far superior to previous exhibits, and of bulls of various breeds were a number of entries, most of them superior animals.

Sheep at this show almost surpassed the cattle in regard to merit—the pens of newly-imported 1 bouillet merino rams which were exhibited 1 greatly admired for their size of carcase, length of staple, and quality of fleece. Several fine 2 Negretti rams were also exhibited, as also some 3 superior crossed Negretti lambs. In the class 4 colonial merino ewes, cross-bred merinos, and 5 goats, the exhibits were good. Only two pens 6 of wethers were shown from Boston district, by 7 breeder, Mr. James Stewart. Usually the 8 butchers compete for this prize.

Horses did not show up in numbers equal to previous years. Those exhibited were, however, 9 of commendation. Only two imported sires were 10 under Class 1, but of imported cart-stallions 11 four animals were paraded in the ring.

The exhibits of produce, poultry, dogs, &c., 12 in the Market-house, fell far short of the display 13 on past occasions, but the quality as well as the 14 variety of the exhibits in the produce and food 15 classes were interesting and worthy of the several 16 awards which were made by the judges.

Wool, at present our principal exports from 17 the colony, has turned out well during the year, 18 both in regard to yield and value, and sheep-farmers 19 have been gratified in receiving good prices for their 20 clips. The value of Natal grown wools, in the 21 colony, during the year, has ranged from 7½d. to 9½d. per lb. for good 22 and from 10½d. to 13½d. for washed fleeces—23 quality, and length of staple determining the 24 value. Large quantities of wool (yearly increasing) 25 are shipped as scoured snow whites, some parcels 26 of which, being of good staple and well got up, have 27 realised London equal values with ordinary 28 Uitenhage whites.

During the past year several importations of 29 valuable live stock have taken place in the way of 30 entire horses, draught stallions, Rambouillet and 31 Negretti merino rams, and further arrivals are 32 expected. These and former importations we may 33 in due season reasonably hope for considerable 34 improvements in the flocks and herds. Several 35 ostriches have also been introduced coastwise.

The erection of wire fencing continues to 36 be an increasing headway in various directions, 37 and large extent of land must have been thus 38 enclosed since I last addressed you. Many, however, 39 do not enclose their lands, or to form paddocks, 40 are prevented from doing so by the difficulty of 41 procuring suitable timber for the purpose, or the 42 needful timber for posts at sufficiently reasonable 43 price. As time goes on, however, large tracts 44 of lands will be adopted to a large extent.

One objection to wire fencing is its partial 45 invasion of the liability of stock getting entangled 46 therein.

One sign of substantial progress and economic 47 labour that has come under my notice during the 48 year is the successful application and use by Mr. 49 G. Richardson, of Faulklands, near Pietermaritzburg, 50 of the steam plough, and of the harrows worked 51 by the same agency—200 acres having, I believe, 52 been fully cultivated by the steam plough.

Agricultural prospects on the coast have 53 been improved during the past year, rain having 54 been frequent and evenly divided along the coast 55 belt. The staple export product of the coast, is 56 reported to be yielding a good return, while the 57 growing crops will well for next season. The crop 58 of 1879 amounted to about 8,000 tons. This year's 59 crop is calculated to yield from 13,000 to 15,000 60 tons, at an average

This gives £260,000 to £300,000 as the turns from sugar this year.

also turned out a better yield than for a past, although many coffee plantations lowered to die out, or have been cropped with drought and the borer insect played such havoc. A few small plantations, or plots of coast, in Victoria County, also in other re under tea culture, with fair success. A resident at the Isipingo, informed me last with the exception of the last two or three had not purchased a single pound of maize for his household during six years past, using what he had himself grown, which he of very good flavour. This shrub does in many localities in our uplands. Arrow-pepper, ginger, and other exportable products still continue to be grown on the coast exported to a small extent. The delay attendant on effecting sales and returns tend to retard an extended production. articles of limited consumption and defrequently to be held for months after arrival can be effected at anything like fair prices.

grown in our midlands, but on the coast to a larger extent, fully supplying all local demands for unmanufactured articles.

continue to be grown to a large extent by the coast, these people requiring to dispose of as soon as possible after reaping, to enable them to meet other demands. The value of this low until the Coolies have sold out. Some of coast-grown maize have lately been sold at a low price,--prices ranging from 7s. to 10s. 200 lbs., partially to supply a demand which exist at the Cape and Port Elizabeth--for feeding ostriches--so long as we are able to grow against imported maize. At present the prices on the coast has risen to 18s. and 19s. I believe some shipments of maize are sent from Europe to supply the demand. On the coast during the last year or two reaped fully 50 per cent.--especially along the lines of the railway--which has greatly increased the sugar and other enterprises.

I have been pleased to learn, from several sources, that the owners of sugar plantations, who have been able to avail themselves of the advantages offered by the Central Sugar Mill ("The Usine Centrale") at Port Elizabeth, in crushing and manufacturing its sugar during the present season, have been satisfied with the results in every case, both as to quantity and quality of the sugars produced. That several plantations have expressed their intention to close their own mills next season, and crush their crop at the above splendid mill, which is capable of turning out 2,500 tons of sugar in the season, to a value of, say,

these gentlemen, though forced to send their crops of twelve or fourteen miles by rail (Imperial), nevertheless intend to repeat the same.

Here, then, is a proof of what I have hoped as my hope and opinion, that the hitherto surrounding the production of cane of limited means is to be overcome by the Mill system--one party being employed in the more simple employment of growing, and the manufacture of the cane into sugar, an enterprise made a profitable one to both, increasing the exports and wealth of the

referred to ostrich farming in my address of 1878, as then engaging a deal of attention in the Province of the Cape Colony. In July 1879, I travelled to Grahamstown, Graaf Reinet,

and other places, I was much surprised, notwithstanding all I had previously heard regarding the prosecution of ostrich farming, at the extent to which the breeding of and dealing in ostriches had attained, and the large returns which are, in many instances, derived by the hatching and rearing, the purchase and re-sale of birds, and the crops of feathers which are plucked from them (according to the fancy of the owners) every six or nine months, as also at the large sales of feathers held on the market at Port Elizabeth, every week, on Mondays and Tuesdays, throughout the year. These sales average from £8,000 to £15,000 weekly, the first amount being considered rather a low return. The total value of feathers sold on this market alone (irrespective of sales inland, or in the Western Province, where ostriches are also bred), during the six months ended June 30th this year, totted up to £276,188 1s. 10d., and for the year 1879 the total sales were £391,129 11s. 8d. I think I may safely put down at least two-thirds of this sum as the returns from domesticated birds, the proportion of wild feathers being very small.

One gentleman, Mr. Distin, of Tafelberg-hall, Graaf Reinet district, has about 1,000 breeding birds and innumerable enclosures on his farm. He is supposed to realise at least £10,000 a year by ostriches.

The common prickly pear plant (*Opuntia vulgaris*), which, having spread itself over large tracts of country, had previously been considered a pest, and large sums spent by some landowners in attempts to eradicate it, is now found to be good green for ostriches. Stuck on a fork or stick, and run through a blazing fire to scorch the thorns, it is chopped up with or without lucern. Mealies and barley are also used to feed with.

I was informed that the first census taken of domesticated ostriches in the Cape Colony in 1863 was returned as 88 head. In 1875 the second census returned 22,000. The number is now believed to be quite 100,000. Companies are now being formed to prosecute ostrich farming.

Angora goats and ostriches have all but supplanted sheep in the Zwaart Ruggens and Graaf Reinet districts, as being less liable to losses by droughty seasons. I lay before you two samples of Angora hair from a superior flock in the above district, from which flock I hope in a month or two to introduce six rams. This sample is taken from wethers, and is fully 12 inches in length, and of good lustre. This breeder's ordinary clip was sold at Port Elizabeth in July last at 2s. per pound. The market for this product is rather depressed just now.

## APPENDIX G.

### STEAMER LINES.—HULL TO BENGUELA.

Extract from a letter from Mr. A. K. Rollins, secretary to the Hull Literary Society, dated Cogan-house, Hull, 8th December, 1880:—

"The steamers to which I referred are those of Messrs. Bailey and Leatham, of this port, and of Lisbon. They write me as follows:—'In reply to your note of yesterday, our African steamers leave Lisbon and touch at the undermentioned ports on or about the following dates:—

Lisbon, leave 5th of each month.			
Madeira, arrive about 8th, leave about 8th.			
St. Vincent, " 14th, " 14th.			
(Cape de Verde)			
St. Jago, " 15th, " 16th.			
(Cape de Verde)			
Bolama, " 19th, " 20th.			
Principe, " 27th, " 27th.			
St. Thomas, " 28th, " 31st.			
Ambriez, " 3rd, " 4th.			
Loanda, " 5th, " 9th.			
Benguela, " 11th, " 13th.			
Mossamedes, " 14th, " 18th.			

Benguela, arrive about 19th, leave about 21st.		
Loanda, " 23rd, " 27th.		
Ambriez, " 28th, " 29th.		
St. Thomas, " 1st, " 4th.		
Principe, " 5th, " 5th.		
Bolomas, " 8th, " 9th.		
St. Jago, " 12th, " 13th.		
St. Vincent, " 14th, " 14th.		
Madeira, " 20th, " 20th.		
Lisbon, " 23rd.		

"They also leave Hull about once a month."

#### DISCUSSION.

Viscount Sidmouth said that, as Sir Bartle Frere had invited questions on the subject of his paper, which was of so great interest at the present time, he should be glad of information upon one or two of the topics mentioned in it. First, in reference to the harbours on the coast; his own recollection of Durban was that it had a very bad harbour, and the same might be said of the harbour at Cape Town, Table Bay. The only good harbour was St. Simon's Bay, which lay quite out of the way of ordinary traffic. Supposing that, at any future time—without entering at all into politics—the Transvaal country should become developed, he would ask Sir Bartle Frere whether he considered Delagoa Bay possessed sufficient facilities for affording a good outlet for the products of that country. That appeared to be the only port on the East Coast where a natural harbour existed. Durban could hardly be so called on account of the dangerous bar at its mouth. He should like, further, to know whether Sir Bartle could give the meeting any idea whether the Portuguese Government, which holds Delagoa Bay, was disposed to develop that harbour so as to give facilities for future traffic. Another point upon which he would be glad of information was, as to the possibility of forming a depôt at Angra Penquena. Sir Bartle had mentioned the small group of rivers shown on the maps high up on the West Coast, and that European colonists had already found their way in that direction. Driven by stress of weather, some years ago, to seek an anchorage in that region, he had found it very deserted, and had, in the neighbourhood of the Island of Iohaboe, known for its guano deposits, hit upon a very good harbour, which he judged to be somewhere in the direction of the small group of rivers referred to. As Sir Bartle had stated, as he understood, that European colonisation had found its way there, he wished to know whether it would not be possible for a depôt to be formed at Angra Penquena.

Mr. J. Jones drew attention to specimens of some of the minerals mentioned in the paper, which had been furnished by Professor Tennant, including specimens of coal, lead, iron, and diamonds. Amongst the latter was one of the largest that had ever been found in the colony. It was estimated to be worth £10,000 sterling. He would remind the meeting that Sir Bartle was himself a member of the Turners' Company, through the agency of which, by another of its members—the Baroness Burdett-Coutts—the diamond trade had again been brought into eminence in this country, after having been lost since the reign of George II. It was by means of the premiums offered by this lady, that Clerkenwell had now attained the highest point in the trade of diamond-cutting.

Mr. Hall said Sir Bartle Frere's paper had the especial merit of pointing out the great advantages of South Africa as a field for emigration, and he should like to ask whether Sir Bartle, from his intimate knowledge of the country—considering its advantages and disadvantages, the country being destitute of a good coast-line, and harbours for mercantile purposes—really thought South Africa a good colony for British

workmen to emigrate to. Every means of work was possessed by the public of the Cape, Australia, Canada, and the United States. If the paper should be published, he would from Sir Bartle's own lips whether South Africa was in his opinion—with its disadvantages weighed against its advantages—was an eligible field for the British settlements.

Sir Bartle Frere, with regard to harbour, that he had omitted reading that section of his paper, for want of time, having already read it, and had pointed out that one of the great advantages of the coast was an accurate survey by responsibility of her Majesty's service. Fog was the great valent, and good charts and sailing directions would be of especial value. He felt no very considerable coasting trade would, in his opinion, be carried on from that coast, and that brought into direct communication with England as her Majesty's Government could obtain of the coast. A considerable trade was already on, and steamers ran pretty regularly to near the mouth of the Orange River. The southwards to the group of rivers mentioned passengers at Angra Penquena. It was very good advice on the subject of Mr. Hall's question of emigration; but, if one of the best climates could be an inducement, emigrants would find no severities of heat or cold in almost every part of South Africa could thrive there; and, above all, they were settled communities of men of their own blood and Dutchmen near akin to us, who were them with as much hospitality as they could give in England, if they did not like to face the world and make a home for themselves. The more I question the more convinced he felt that the regions of the earth where an Englishman happier who was compelled to seek a home in native land. There could be no question of it. Bay was a magnificent harbour, and that railway would make it very serviceable; the meeting could readily draw its conclusions as to the likelihood of this proving of great importance in the near future.

Sir David Tennant (Speaker of the House of Assembly) was delighted with the manner in which the history, character, and mode of life in the colony had been set forth in the paper, and he could fully endorse Sir Bartle's opinion as to its eligibility for British emigration and enterprise. It could equal it. Of course, emigrants going to Africa must expect to rough it. One of the great advantages experienced by strangers was the abundance of the labour market. Labour there was dependent and less reliable character than in this country, whether the fact was attributable to the sparse population, or to the manners of the races. They took life more easily, and were of greater extent, than working people in this country. Strangers would have that difficulty to but they would find that eventually things would come down. The insufficient supply of the labour was one of the great disadvantages; and, as our labouring population, in emigrating, they would have to enter the labour market, as competitors with the coloured people. It would be well to state difficulties, and not to present a picture; but any industrious, enterprising, and well-to-do man would do well in any one of the colonies. The climate, the mode of life, the facilities for communication, all tended to inspire confidence in the country, and the assurance that, with diligence, he would

and raise himself in the social scale. As regards the Cape Town, the chief town in the colony, it was shunned in former times from its exposure, but what nature had denied, art had not, and, by means of the docks and the breakwaters, it had now drawn a very large commercial and shipping trade to the colony. It was a perfectly secure port in all weathers, and it was only to be regretted that the docks, when first planned, had not been made at Alga Bay was more exposed, but improvements were to be made there, and, when they were made, a safe and commodious harbour would be added to a most enterprising port, the Liverpool of the Cape. Port Elizabeth is virtually a roadstead, and harbour improvements will, in the end, secure it. On all those harbours a very large outlay had been made by the Colonial Government, which could devote a large expenditure to them. From five a railway ran northward into the country, and another which had feeders on each side all the way, and another railway ran also inland, the two together being about 1,000 miles in length. Another line was now probably eventually to be extended to the inland fields. As those districts now formed part of the colony, there was, of course, every desire on the part of the Government, to afford facilities for reaching them by steamer. As Sir Bartle had said, the only certain progress was to be achieved, not by the action of the native races, but by the amelioration of their condition, and by Christianising them. aided by moving a hearty vote of thanks to Sir Bartle for his admirable paper, coming before him he did, with his great knowledge of the conditions and wants of the country, and as the friend of the South Africa, and beloved by them all.

He said that even supposing for the present the trade and of industrial development, Port Elizabeth should never be so improved as to make it a harbour, Port Natal furnished that requirement proved during the late Zulu war in the action of the troops. Having known Natal well, he could say there was no colony to which he would readily emigrate, if he had his time over he would advise sober, industrious men to go without the slightest misgiving, for they would find that there they would live an Englishman's life. A circular upon colonisation would be sent from the Colonial Office in a few weeks, which would give every information with regard to Natal, to which it was sent. Sir Bartle Frere had added another to the gratitude of the British public, by supplying his extensive experience, a knowledge of the country, so much wanted in this country, and of the future of that great dominion. He expressed his pleasure in seconding the vote of thanks.

After, after hearing the paper, felt inclined to think that the locality of the Garden of Eden was wrongly supposed to lie at the junction of the Nile and Euphrates, and whether it should not be fixed in South Africa. Much was now talked of "three F's," but South Africa possessed "three A's," copper, and cattle. Its industrial products would be made enormously useful, and he hoped that emigrants would be induced to leave the bleak and unwholesome parts of Ireland, and find a new life in South Africa. He trusted that, under the sanction of the Government of England, and the wise counsel of the Cape, Europeans and natives might be made to prosper under the Divine blessing.

Lawrence, G.R., pointed out that roads, one of the necessities of a new country, were being constructed in the Cape Colonies. With railways, roads, and emigrants, the country would soon become prosperous. With regard to the labour difficulty, the Cape could only engage themselves for a term, and

would then, in spite of every inducement, return to their people for a period of idleness. But Englishmen, too, were fond of observing St. Monday, and the natives only manifested the same desire for periods of idleness in a more rudimentary form. If treated with kindness, they would gradually appreciate and adopt habits of civilisation, and would aid the Europeans in making the South African communities sound and prosperous.

Dr Maun said it could hardly have been expected that Sir Bartle Frere would have been able to devote so much of his time to the service of the Society as he had in producing the admirable paper just read. One of the most valuable portions of the paper was the point made in it of the necessity for irrigation, in regard to the future of the country. Along one side of South Africa ran a range of lofty mountains, which were deluged with rain for six months of the year. That rain escaped to the sea by a very rapid fall, and for the next six months the country was parched; but as soon as that water should be properly husbanded, the land could be made to produce the most valuable harvests. Throughout many parts of it corn could not be grown at present in summer, but, when irrigated, the finest corn crops in the world would be produced in the dry, sunny season of winter. Since 1857, the most rapid progress had been made in the country. Then no steamers sailed for Natal, and to reach it, he had himself, in that year, had to take a passage to Calcutta, land at the Cape, and go on by colonial steamer. At that time, Natal was occasionally two months without letters from England. Now we read in the evening in London of the events that had taken place in the Transvaal on the morning of the same day.

A Member alluded to the construction of railways now going on at the Cape, and said that the colony, having now got a fair start, would, as greater progress in that direction continued to be made, become one of the finest countries in the world. The mountains along either coast formed natural reservoirs, and, by means of irrigation works, a plentiful supply of water for the country could be obtained.

Sir Bartle Frere, in acknowledging the thanks which had been given him, urged their indebtedness to an old and valued member of the Society for the addition he had made to the evening's instruction by the beautiful collection of minerals he had placed on the table—he alluded to Professor Tennant. He was glad to notice that the trade of diamond cutting had again taken firm root in this country, and that the interesting processes connected with it could be witnessed by visitors in the manufactories in Clerkenwell, through the kindness of the gentlemen who had been instrumental in planting the industry in London.

Mr. Jones added that in a recent competition between diamond cutters in Holland, France, and England, the finest result in polishing the rough gems had been attained by the workmen of Clerkenwell.

The Chairman, in putting the vote of thanks to the meeting, alluded to the gratifying fact that witnesses after witnesses should have risen in the room to testify to the extreme value of the paper, and to emphasise the gratifying account given from Sir Bartle Frere's experience of the present condition and future prospects of South Africa.

#### TENTH ORDINARY MEETING.

Wednesday, February 9th, 1881; Sir PHILIP CUNLIFFE-OWEN, K.C.M.G., C.B., C.I.E., Member of Council, in the chair.

The following candidates were proposed for election as members of the Society :—

Bolas, Thomas, 2, The Terrace, Turnham-green, W.  
Chambers, William E., Eversfield, Sutton, Surrey.  
Courteen, Henry, 336, Clapham-road, S.W.  
Felkin, Robert William, F.R.G.S., Pennfields, Wolverhampton.  
Kirkham, Thomas Nesham, 21, Abingdon-street, Westminster, S.W.  
Lee, Edwin, 43, Devonshire-street, Keighley.  
Le Rossignol, Francis, 1, Gresham-buildings, Basinghall-street, E.C.  
Magniac, Arthur, 36, Hertford-street, Mayfair, W.  
Martindale, William, 10, New Cavendish-street, W.  
Murray, R. W., 179, Upper Thames-street, E.C.  
O'Donnell, William Arthur Maxwell, 4, Gladstone-street, London-road, S.E.  
Parr, Samuel, 7, Finsbury-square, E.C.  
Pheasant, William Craster, 8, Edwardes-square, Kensington, W.  
Rafferty, John Henry, 4, The Terrace, Richmond-hill, Surrey.  
Swanzy, Francis, 147, Cannon-street, E.C.

The following candidates were balloted for, and duly elected members of the Society :—

Cole, Alfred Clayton, 64, Portland-place, W.  
Cook, Henry, Barrow-in-Furness.  
Gibbs, George L. M., 46, Grosvenor-street, W.  
Green, Herbert, Tovil-house, Maidstone.  
Liardet, John Evelyn, 4, Breakspears-road, Brockley, S.E.  
Littler, Ralph Daniel Makinson, Q.C., 1, Plowden-buildings, Temple, E.C.  
Lockyer, George, jun., Beaconsfield-house, Godolphin-road, W.  
Lovegrove, James, 18, Urswick-road, Lower Clapton, E., and Town-hall, Hackney, E.  
Lyte, F. Maxwell, F.C.S., Cotford, Oakhill-road, Putney, S.W.  
Payne, Septimus, F.R.G.S., Castle-house, 44, Mildmay-grove, Mildmay-park, N.  
Shuttleworth, Joseph, Hartsholme-hall, Lincoln, and Stamp End Works, Lincoln.  
Wills, George Sampson Valentine, The Westminster College of Chemistry, 60, Lambeth-road, S.E.; and 116, St. George's-road, S.E.  
Wright, Bryce McMurdo, F.R.G.S., Heaket-house, 54, Guildford-street, Russell-square, W.C.

The paper read was on—

## THE PRESENT CONDITION OF THE ART OF WOOD-CARVING IN ENGLAND.

By J. Hungerford Pollen.

In the remarks I am about to make on wood-carving, I shall not enter into the higher aspects of this kind of art. It is, indeed, one side or branch of the sculptor's art. Sculptors of the greatest attainments have left us statues, busts, medallions, and other objects equal to what has been accomplished in harder materials, ivory, marble, and bronze. Many small pieces in the South Kensington Museum, as Sir Philip Cunliffe-Owen can tell you, will fully satisfy those who look for what can be done in hard woods. But I shall have enough for my present object if I can call your attention to carving, not as a branch of sculpture in this higher sense, but as a handicraft of great use, and I may say of necessity, to the architect and the cabinet-

maker—carving with sharp tools on softer, only moderately hard, woods. The carving which I am principally concerned, is executed in pine and ash. Walnut wood is more procured in Italy and France than in England, and it is of so fine and tenacious a grain, that it admits of more delicate workmanship than which I wish now to advocate. Wood-carving is unfortunately, at a low level in this country at present; speaking generally, it is almost a lost art. The only traditional school that has come down has its home in the dockyards; even from that quarter it is being driven by iron and steel. A persons present to-night may have observed Vauxhall-bridge a ship-breaker's yard, and been struck with admiration, as I have, of admirable figure-heads of colossal proportions sometimes to be seen there. They are well-proportioned, often dignified, designed and carved with a perfect feeling of propriety for the effect they produce, all being calculated to show from a distance. I do not know whether there are any artists still capable of these successes. It will be a real matter of regret that one or two of these works should not be preserved as monument studies, rather than be sawn up for firewood.

It would be unfair in a discussion on this subject to omit mentioning, with the highest honour, such a carver of fancy work as the late Mr. Rogers, and some half dozen great London firms of cabinet makers. But his work, again, is of too refined a kind to be included in the remarks I am making; it is occasional work, equal to that of the Florentines, Romans, and Venetians of the 16th century. What we want now is such carving as one can expect from skilled joiners, from a regent, and at moderate cost. Artists, architects, furniture makers, and the employers of all them, want good current work, worthy of churches, state buildings, and houses we are building at such great cost all over the country.

How much of it do we see in the great churches of our day, or in public buildings, or in country houses? There is a certain quantity in the Palace of Westminster, not of much importance, but in general the poverty of this charming art of decoration is mortifying. Doorways, and panelling have been starved down to yards, longes, and miles of the product of the mould plane. Even this much of handiwork is generally replaced by the steam plane. A good deal of what passes for good carving is produced by machine which multiplies, by mechanical copies of any given figure. I suppose, too, most of us have had experience of that dilapidated lodging-house furniture met with at water places—black horsehair sofas, with gaudy carvings chopped into leaves and curves, and sideboards of the same character. On the other hand, at the eagerness with which old chairs and furniture are bought up, not alone because they are old, but because a certain elegance is discernible in the simple carving which was all but universal bestowed on them less than a century ago.

Now, carving in wood is as necessary to architecture as carving in stone. Many buildings that are not wanting in external dignity and splendour, are finished from foundation to ridge without the help of a stone-cutter, but are fitted in the matter of wood-cutting within (

sole feature that gives interest to some old iron houses is their carved wooden doorway porch, e.g., in Queen Anne's-gate, Westminster, and in some by-streets of the City. And remark does not apply to civil buildings only. Carving is the glory of many of our old churches, for wood is the material with which churches, like houses, are furnished.

As regards architecture, we have lived to see two fashions in this century—the Pointed style, and now, recently, public taste is setting in the direction of what is called by the venerable name of Queen Anne, in other words, classic or Italian architecture, as naturalised here in England by Sir Christopher Wren, and their successors. Both classes of architecture are incomplete—absolutely incomplete—wanting wood decoration.

Subjects have been in advance of carvers, and the exteriors of modern buildings far better looked than the interiors. Great exertions have been made by the late Sir Gilbert Scott, and architects, to train carvers of stone, but much has to be learned and practised by the carvers of wood. We seem to have stopped half way in the revival; and, as I wish to direct attention to a subject that seems to me very serious, I must proceed to these revivals in detail.

Begin, then, with the pointed style, considerate at which the world moves, and the changes of fashion, this mediæval style has had a long reign. Pointed architecture has been more popular in our country than on the Continent, and the principles of its structure and construction have been more widely, perhaps better, understood. Now what part has wood-carving had in the revival? We have rebuilt the Houses of Parliament, we have just finished the new Law Courts, and have erected churches innumerable. In many of the latter shall we see carved seats, crocketed canopies, or carved shrines? Progress has been made in regard to the carving of civil architecture? The throne in the House of Lords is, perhaps, the best piece of work done since the days of the Legislature, but the general effect of the building are devoid of interest.

Let any one walk into Henry the Seventh's Chapel in Westminster Abbey, or that of St. George at Windsor, and imagine how dull and stingy either building would be without stalls and canopies that rise 15 feet or more on either side. The stall work of both is a late date in Pointed architecture—a relic of decay—yet what noble achievements in these seats and canopies are! The stalls, or hinged seats, have brackets which support a sort of seat when turned up. The stalls are supported by masks, grotesque figures, and foliage, with foliage, gracefully turned. The stalls are quaint, humorous, and always carved with wit. The carvers have been their own masters, and have evidently taken pleasure in their work. Perhaps a certain amount of humorlessness is characteristic of all good carving, but the date or style.

Our modern churches look cold and dull, for great sums of money have been spent on them, from want of this kind of furniture, in general. Again, as to roofs; no structures could be so good as the great wooden roofs of the Middle

Ages. Some were supported by king posts, queen posts, hammer beams, and a forest of smaller supports: intricate, yet not without regularity and order: and always having figures of angels with outstretched wings on the ends of the hammer beams. We have a superlative example in Westminster-hall. Smaller roofs of the same construction are to be seen in some churches of Norfolk. All of these are dependent for much of their interest on the carved figures that adorn them. Perhaps such costly undertakings are scarcely to be hoped for in our times. Yet the hall of Lincoln's-inn, with a beautiful roof, was erected by Mr. Hardwicke forty years since. With the exception of occasional restorations of college halls, I doubt whether we have followed the example set so long ago.

Another fine form of roof or ceiling one would gladly see reproduced more constantly is that of square panelling with carved leaf work on the points of intersection. Most of the ceilings we find in modern churches, or in houses built in the mediæval style, are merely panelled with rails moulded by the plane.

Now, is it reasonable to suppose that carved leaf work of this kind—light, bold, broad, and sinewy—though it is not of extraordinary difficulty, cannot be added to ordinary panelled work, because of the cost? As we see it in old work, it is simple and coarse, but effective. It does not require an accomplished hand for its execution. Yet the quick, ready hands from which such work ought to be producible with ease and at moderate cost, cannot be found.

In making such a statement, I feel bound to acknowledge the services to wood sculpture of Mr. Brindley and his pupils. He has restored stall work and tabernacle work of all kinds. But such skill is confined to very few firms in London, Peterborough, and perhaps one or two other favoured cities. We have nothing like the amount of skill and talent in the wood-carver that we can resort to in masons and carvers of stone.

If the mediæval revival has not seen a lively and growing school of architectural wood-carvers, ready to decorate stall work and tabernacles, panelled walls and ceilings; neither can we point to any solid achievements in modern mediæval furniture. One or two light and well-constructed pieces, such as sideboards, buffets, &c., have been seen in the great International Exhibitions. But in furniture, far higher accomplishments are required of the carver. Those old cupboard, cabinets, buffets, chests, of French or Flemish origin, which are to be seen in the South Kensington Museum, and picked up in shops, are carved not with mere leaf-work, but with figure subjects. Little compositions, illustrating old legends, form the chief decoration of this old furniture; but we look in vain for it in our own reproductions.

If we are to go on building, fitting up interiors, and making mediæval furniture, it is in the direction here indicated that we want training and practice. Something should be said as to the treatment of carved woodwork and carved furniture. Old work was partially gilded. In roofs where it had little light upon it, it was painted and gilt. It was never covered with glossy varnish, as so much of our modern woodwork is.

Let us turn now to the decorative woodwork of

a later period, spoken of sometimes as a sort of halfway step in the direction of Italian art, that purely domestic style which we call Elizabethan. It belongs, in reality, to the earlier revival in this country of classic or Italian architecture. It was neither so artistic in outline, nor so fine in detail, as the art of the time of Henry VIII. He had Holbein and other foreign artists in his pay—men educated under the revival. The period of Elizabeth was later. The kingdom was more or less isolated from Continental Europe, and our style of architecture, and of the woodwork and sculpture that belongs to it, became national. It is the Elizabethan house, its interior panelling, its fanciful carving, and massive furniture, which has retained so great a popularity down to our own times. Country houses of this kind have been re-fitted, and others built in recent times, and we continue to build them still. All the woodwork of the old houses has a distinct and national character. But it had this character owing to certain national prejudices, and to the difficulties that stood in the way of sending artists to Italy, to study in Rome or Florence, as was the custom of the various States of Germany, Spain, and the Netherlands.

Nevertheless, builders and projectors of Elizabethan houses aimed at following the lead of the artists of Italy. In that favoured land, the enthusiasm for antique art, and the success with which it was cultivated, were astonishing. Italian painters were often architects as well. They designed churches and houses; they caught up the threads of old traditions, and carried them out into a thousand delicate developments. Wood-carvers adopted the mouldings, capitals, brackets, arabesques, and leaf-work, which they found on ancient monuments. Though they borrowed these details from architecture, they modified, simplified, or multiplied them, according to the opportunities of the objects they had in hand, and the nature of the materials in which they had to work. In this respect, they did what wood-carvers had done for the Pointed style. The egg and tongue, the drip moulding, the ogre mouldings covered with leaf-work, had all been adapted to their service. But, in the hands of the earliest and finest carvers, an immense variety was introduced into these important elements of decoration. So also with capitals and brackets, the classic acanthus was put to universal use. It was varied in ten thousand ways. Yet we recognise in all these Italian capitals, or brackets, or scroll work, in which this leaf is used, the old type. We cannot but see, moreover, what a pregnant type of foliage it is, and how inexhaustible in its application, offering an endless field for variety, and yet preserving that unity which is one of the great principles of art.

Here are examples of a large and a small piece of furniture, belonging to the best period of Italian wood-work (bench and mirror). We must keep this Italian wood-carving before the mind, if we wish to understand that of our own country.

The peculiar character of our own Elizabethan art, and, indeed, of the contemporary carving of France and Germany, and still more of Flanders and the states of the house of Burgundy, was due to the firmer hold in those countries of old mediæval ideas. We, in England, retained a great *love for the old houses, old feudal customs, the*

state and hospitalities of former days. The Elizabethan house was still surrounded by a moat. It had courts and gate-houses. The doors were of old ledge-doors of massive oak, sometimes pieced with shot-holes. Then we preserved the tradition of one vast room, or hall, to which the drawing rooms, and libraries, and galleries, were offsets. Into the hall travellers and wanderers were welcomed. The entrance was a passage panelled off from it, so that access could be gained through it to the rest of the house. Over the passage a gallery commonly led from one end of the house to the other, still across this great hall. These panelled screens and galleries are richly decorated with carving of several kinds. A huge place was provided on one side. The upper part was raised, and the handsomest seats were placed there. There sat the guests of highest rank, the wall side only. The salt, the emblem of hospitality, was placed in the middle of the table. Guests of inferior rank sat at tables running down the length of the room. The walls were panelled with oak, to a height of ten or twelve feet. These noble halls are, as we may say, "the making" of the Elizabethan house, as they were of the earlier Tudor houses, and of old castles and manors, and granges, time out of mind. The architectural disposition, inside and out, was of great measure, dictated by that of the old Pointed style. The Renaissance was adopted with enthusiasm, but the parts and details were fitted to a system of mullioned windows, pointed arches, and Tudor arches. Builders thought of the new style and expressed their thoughts in a borrowed language. We see curious façades, displaying of columns of the "Five Orders," one over the other. As to details of wood-work, the fire-place was put together over a Tudor arch, like all the doorways of the house. Round arches were a late adoption. The hall-screen had classical columns, capitals, and brackets. Terminal figures with Ionic capitals, supported the large and projecting cornices. Both in these large screens and the chimney fronts, the details are curiously medieval in character. There are Doric columns from the ground; a second series over them; deep recessed panels, fronted by arches; over the whole, generally the heraldic achievement of the family. The boldest carving is often seen in the details of heraldic carving; the mantlings of the helmet coming down in wide sweeps of wood carved relief. Every detail in this kind of carving attained to a great degree its abstract and conventional design. In the richest and best examples, screens and fire-places, figure sculpture is employed. The virtues, for instance, in hooped petticoats and classic armour. Arabesque work, that is, scroll work or human masks, with scrolls of foliage, were carved with spirit, and used to cover imposts or panel surfaces, or coupled together and carried out into cornices, and the upper borders of continuous panelling. Another favourite element of decoration is that scroll work of flat relief, of the bosses of turned and split wood at intervals, of strap-work. The cornices of chimney-pieces, screen divisions, are often interrupted by wood of this kind lapping round it, and passing over the members of the structure above or below. It would seem to be an idea borrowed from the old Egyptian work that formed so important a feature in

ors, and other wood-work of the middle is strap-work, and the larger surfaces of heraldic scutcheons, borrowed, probably, notched and curled edges of boiled and leather, are very effectively employed in wood-work. In one form or another, reed, plated, or curled decorations are met all sorts of surfaces. They are of great

again, look at the furniture of this system. acorn table legs, with gadroon ribs on the and acanthus leaves on the under surfaces. acorn shape elongated serves for stair and for supports to side-boards and fronts. Other notable objects of furniture bedsteads. The bed heads are divided into panels, and the tester is supported by posts, sometimes by fluted columns, finished as they rise. Rude terminal figures are generally introduced into the

The tester is a panelled frame. the details of Elizabethan woodwork are be Italian. The mouldings are partly in the plane, partly fitted in with billets and ridings, but worked, it must be remembered, by uneducated carpenters, joiners, and

re Elizabethan carving detail by detail, faults, short-comings, and inconsistencies at a graceful and beautiful ideal; tied out—often ignorantly—as best it can recognise in it a real character; it is full of even grotesque incident, but it speaks of its day. And this is what gives and meaning to good intentions in the Elizabethan age was full of a strange thought—chivalry, of a kind hospitality, thirst for new adventure, for new knowledge and simplicity—of generosity, thirst for wealth, and stained with cruelty. tempt to reproduce wood-work belonging to that period, we must do it with some care for the interesting side of an age so full of art, so full of inconsistencies, or compound ideas. If, on the other hand, copy this old work, and with labour and allow its oddities, without knowing how their art in our turn, as they modified it in theirs, we do but reproduce the side of it. The neater, the smoother, the artificial imitation, the more glaring results of our work. Any architect who has a work of this kind in hand, and to get it, will, I think, agree me as to the unhappy results he has often to meet. It is remembered that the wood-work of the sixteenth time was cut by country workmen, astonishing that hands so well practised in the business of carving should have been very country in England, from Northampton to Cornwall. Could we go to any assize and reckon on finding two or three good carvers and their apprentices, ready to do panelling, heraldry, furniture—all intended to fit up a stately palace according to the taste of the day? No; I fear that out of the hundred, or one or two other owners where some man of special training made a school for himself, we should find what we want in vain.

Well, let us turn to a later fashion, that which is becoming so popular now under the name of Queen Anne.

Two great architects put the principles of the Italian Renaissance into exact form in the 17th century—Inigo Jones and Christopher Wren; Vanbrugh, Chambers, Kent, Adam, and others followed. Numerous examples of the wood-work designed by these artists remain in public buildings, churches, and dwelling-houses. They had fewer decorative resources than their contemporaries in Italy and France. One great name, however, belongs to the profession of wood sculptors of the century, that of Grinling Gibbons. His foliage, flowers, birds, and other details have the sweep and delicacy of Nature, so far as an approach to Nature can be carried in decorative carving. All the carving of the 17th and 18th century may be called architectonic. It was put to the service of interior decoration. Let us notice it in detail. Houses were no longer built with the great halls already noticed. Churches, however, and large public halls, such as those of Greenwich Hospital, Kilmainham Hospital, in Dublin, and other places, were often screened off from the doors. Such screens are regular and orderly façades, with arched entrances, surmounted by a pediment. The walls of these structures, and of rooms generally, were divided by columns or pilasters, fluted, and with carved Corinthian capitals. The panelling is no longer of the old sizes, but in very large divisions; one of dado height, with tall panels above. They stand well out, and are enclosed within bold roll mouldings, projecting beyond the surface of the panels. Where these panels are of great size, as in some public halls, the mouldings were carved. Wreaths of leaf-work stand out in relief on the architraves, that finish the wall panelling; and that surmount the openings of fireplaces and doorways. These doorways, even inside the rooms, are generally covered by a pediment. The picture frames that form the upper portion of the chimney fronts, are also surmounted by a pediment, pointed, or round, or interrupted in the middle. Garlands of leaves or flowers, with bold side brackets, in the form of volutes, over which the foliage falls, or from the eyes of which another scroll of leaf-work springs, form the side decoration of the chimney fronts of the more correct Wren period.

I should be taxing your patience too far were I to attempt to follow the wood decoration of this fine character through all its details. We may, however, notice some special features, out of which the wood-fitters and joiners of the last century may be said to have made their decorative work, and these are the very elements we want our wood-cutters to have at command to-day.

First, figure sculpture. Somehow in this country, our wood-carvers have never been strong in this essential matter. Even in Wren's time, and that of his successors, beyond an occasional artist, there does not seem to have been any possibility of commanding the services of carvers educated to this extent. We find heads—of cherubs, of women, &c.—occasionally well modelled and finished. But the contemporary Italian and French wood-cutters could beat us out of the field in this respect.

Of foliage, the English carvers were masters

As for the foliage of Gibbons, it was of all kinds, and animals were introduced among the rolls of his stems and flowers. It was abundant, and yet delicate. Generally, he used lime-wood; and his work is such as naturally found its place as an addition to actual architectural details, and was applied to friezes, or placed under pediments, or on the architrave fronts of chimney pieces. Such carving as that of Mr. Rogers, had more of it been devoted to decoration, would be invaluable in these reserved spaces. (Some of Gibbons's carving can be seen over the communion-table of St. James's, Piccadilly.)

It is to be noted that, in architectural carving of this period generally, the acanthus and the vine leaf are the only leaves employed. There is, also, the honeysuckle ornament, and anthemion, or leaf arrangements similarly composed. In later work—Adam's, for instance—the olive, or a leaf of similar shape, was added. Speaking generally, however, the leaf used is the acanthus. It is cut on capitals and under brackets. Portions are composed over the surfaces of mouldings, in a hundred varieties, and with endless inventiveness. Yet it is always recognisable, and helps to preserve the unity of the general design of the decoration. The little, feather-shaped leaves on the correct English Corinthian capitals seem to me the poorest and driest examples of its use.

On the furniture of Queen Anne's time you see the acanthus leaf on the bulging legs of chairs and tables; and broken pieces of it on the tops of bed testers, on chimney pieces, and round looking-glass frames. The finer, more wiry work of Adam, and the Chippendale furniture, is decorated with sprigs, or portions of this leafage. And some small Adam mouldings are entirely worked in tiny acanthus, even when the width scarcely reaches 3-8ths of an inch.

As to mouldings, something may be said. Mouldings, of course, represent the decoration of edges. Wood being framed together often in different thickness, these edges have to be provided for. The decoration of wood edges takes so large a place in the arrangement of panelling, of picture-frames, of fireplace openings, doorways, and so on, that it forms the most noticeable decorative feature at the command of the carver.

It is worth observing, how few the mouldings of these periods are. They are derived from classic Rome. There is the egg and tongue; leaf mouldings; billet mouldings, made up of small square dies separated by hollows; bead mouldings; ribbon mouldings (guilloches); square key frets; the Vitruvian scroll; little else. Yet few as these are, the shades of variety to which they lend themselves are endless; partly by the size, partly by the shape of the egg and the anchor, or by carving the egg surfaces, or by various treatment of the acanthus leaf-work, where it covers the surface of the moulding lines.

The carvers of the last century cut these in soft pine, over long lengths of moulding; often in beautiful curves and turns of the leaf. A slip of the chisel would have destroyed the side of the doorway. There are examples in the Kensington Museum, taken from old London houses, quite complete, and of masterly execution. Could we be sure of getting such sharp, free-handed work done now?

Then as to furniture. Chambers introduced Chinese fret-work, and the Chippendales cut the delicate pierced cabinet tops, and china shelves and table edges, which are so highly prized. The carving of looking-glass frames took the place of little Chinese gardens, with rocks, grouse, argus pheasants, and other curiosities down the edges. As far as architectural carving was concerned, how very few and simple are the elements of this old carving—carving so much in vogue now. I wish I could think that our Queen style was fitting itself out with these simple effective, elements of carving. It is a kind of work which all carvers could learn; which always returns full and redundant measure of labour and agreeableness, for the modest skill it requires. Some London firms well understand this kind of carving; but only two or three establishments, as Putty, or papier maché, or other moulded decorations, are generally provided by the builder. These are used at our picture frames, and the feeble meanderings of putty over their surfaces, and compared with the simple honest mouldings of the Victorian frames. I do not forget the admirable objects we have seen at various International Exhibitions. They are triumphs of skill, and the exhibition of English, French, Italian, or German, deserves honour. But these are objects of special and extraordinary exertion of artists, and are not mental—not works that can be placed within the reach of ordinary buyers, or made without enormous cost of time and labour.

I shall conclude with one or two observations which I hold to be of the first importance, which, I think, may be deduced from the foregoing remarks. First, all decorative carving in the mediæval and Renaissance, has been intimately connected with architecture; and, further, been architectonic in design and details. Tabernacles, pinnacles, and spires of mediæval stall-work, triptychs, and so on, are designed on the lines of external architecture. So with pediments—really, small roofs—pillars, capitals, architraves, and so on.

How is it that wood, so different a material from stone, and being used in-doors under such different conditions from those that govern exteriors, should fall under the rules and lines of actual architecture? Ought not all wood-work to be governed by some distinct principle of decoration? I believe that most designers have asked themselves this question, and battered their brains for an answer. In many cases the honest endeavours of many architects and cabinet-makers show that an answer has been sought, and the general results show how it has been found. Sooner or later, I believe, must all come round to the principle which has prevailed so generally, if not so universally, in the past. Good art maintains its unity. Architecture is the master art in a certain true sense. Sculpture and painting find their true places under its shadow. Great buildings, cathedrals, temples, abbeyes, and halls of justice belong to all who see and use them; in the case of religious buildings, to all who care for religion in the world. Pediments, gables, arches, columns, and so on, not only represent fundamental geometrical figures, which rule the composition of decorative detail, but they are parts of structures the most imposing, the most intimately associated.

animal life, that come within the range of our imaginations. They connect interior decoration with the structure for which they are intended, and give a certain life and purpose to details that would not effectively stand alone. On this part of the subject there is much more that might be said, but, after all, the strongest proof of the necessity of the connection I advocate, is the broad experience of all history.

Of course, the architectonic character in question is one of analogy. Wood carving should be suggestive, not imitative, of architecture. It is on a higher and a broader scale of proportions, in accordance with the continuity of fibre and tenacity of grain of wood as contrasted with stone. The most careful study of examples will set this clearly before us.

Another observation I make is on the extreme variety of the elements out of which such endless carvings, both before and since the Renaissance, have been produced in carving—one or two kinds of leaves, half a dozen types of moulded edges, and of these are convex in sections, some concave, and undulating.

Two of the most dangerous stumbling-blocks to the carver, men who have not well read or kept the subject out—one of their most serious elements—is the vast variety of fragmentary styles in museums. They belong to various ages, and represent many phases of change. The art aims at producing something new. In novelty—actual novelty—is rarely to be had. Traditions of art, descending through the long of the past, reveal to us the unity of principle by which they maintain, not less than the simplicity of instruments, by means of which successes so many to various have been achieved. Michelangelo took his inspirations from studying a few sarcophagi fronts and other marble fragments in a museum. The architects of his day, and of Wykeham, and of Wren's, began by mastering the few native details in use in their day. What a large stock of tools, for works so infinite in variety, that have come down to our time! They are students of nature as keen and true as ourselves, but they sought variety rather than novelty, perpetual freshness of application, of few but beautiful principles. What they did, sculptors, carvers, decorative carvers, can do in their day in our days.

Now, again, if to narrow our field is in reality to increase our insight and inventive powers, it is that modesty, self-restraint, and simplicity which should govern our designs of ornamental work. Look at the decorative carved work, as one sees, for instance, on sideboards; then of game, pheasants, hares, rabbits, and all over it. Some of these compositions are skilfully carried out; but the impression produced is that of redundancy, crowd-want of discrimination, absence of effect, and work often wasted. You see ornamental designs on mirror frames, cabinets, chimney pieces. Such compositions are vulgar, because the artist has chosen details, perhaps from all good original examples, which do not agree with each other. They are like fine expressions of animal rhymes torn from their proper contexts. I compose really well, to know exactly where up, and how to make a simple piece of foliage

or figure set off the space it fills; to possess what we mean by a correct taste, is partly a gift, partly the fruits of thought and observation. To pick and choose, and mingle together in the search of novelty and variety, is the least likely way to acquire it.

If the desire to put too many ornaments is the danger of composition in carving, so to try to follow nature too far is the danger in execution. No leaf, or flower, or other object followed up to realisation, really decorates the frieze or the wood-work on which it is carved; it is better to carve it complete, and lay it on a table, or in a cabinet. When we decorate a frieze, or a cabinet, the ornaments are to be portions of the thing decorated, and worked out, some more, some less, according to the size, shape, amount of plain surface, and so on. Leaves die into the surface, or are only indicated over many places, on the ball of a capital, the tympanum of a pediment. Points in the leaf are here and there fully developed. Figures in bas-relief are often of extreme flatness, or partly flat and partly brought fully out and undercut. Much foliage that would be excellent if indicated only, one sees absolutely spoiled by attempts to elaborate petals, leaves, tendrils, and so on. Even natural proportions have frequently to be modified. Carved objects will often not look correct without this severe treatment.

Opportunities of careful rendering of nature are never wanting to the carver, and his finer skill and deeper knowledge produce their true effect, when he knows how to keep other portions of his work subdued, or but partially defined, and strictly subordinate to architectural requirements.

#### DISCUSSION.

The Chairman said there was perhaps hardly anyone else in the country so competent to give such an interesting and instructive paper as Mr. Pollen had just read, and he thought he must have had practical experience, not only of carving in stone, but in wood also. It had occurred to him, while listening to the paper, that it was a great pity that his words should only be heard by those then present, and how well it would be if the lecture was repeated in workshops, or centres of industry, where he was sure it would not only be listened to with interest, but would be followed by good results. In England, we were in a very peculiar position as regards the art of wood-carving. He had before him the prospectus of a School of Art Wood-carving, which was founded in 1879, by a few of his colleagues at the South Kensington Museum, who, with an eminent manufacturer and other gentlemen, banded themselves together for the purpose, one of the most active being the gentleman who had the direction of the science schools throughout the kingdom. He thought Colonel Donnelly must have taken this up as a kind of relaxation, probably thinking it not so dry, and a little more artistic, than what he had to do, and did so successfully, in connection with the science schools. This was only started in 1879, whilst in Austria, Hungary, Switzerland, and most countries of Europe, the Government promoted schools of wood-carving in all parts of their dominion, and one of the most interesting sections of the Exhibition at Vienna, was the one showing the results of the teaching throughout the primary schools of the Austro-Hungarian Empire. This school was still in its infancy at the Albert-hall, but it had already attracted the attention of the City Guilds of London Institute for advancing Technical Education,

and he trusted that it might become a normal school for other schools throughout the kingdom. After all, wood-carving was a thing which interested almost everybody; boys and even girls were very fond of carving, and they often carved most inconvenient things with their pocket-knives. Now, if this disposition were turned into a right channel, and they were taught in the various schools how they might make use of this love of carving for the decoration of their houses, great good would be done, and much evil would be avoided. It was a matter which ought to be taken up generally, and he trusted Mr. Pollen would repeat his lecture in other parts of the metropolis. He heard, the other day, that 60,000 new houses were built in London and its suburbs every year, and, of course, with such a state of things, there could not be much time spent on decorative wood-work, but there were many people who would willingly introduce wood-carving for decoration, if there were carvers to do the work. He believed that until latterly there had been no means of instruction whatever, except in some of the large firms, until Signor Bulletti, the instructor of this school, tried to start a school of his own. They owed his presence in England to the liberality of the late Duke of Northumberland, and some of the most marvellous carving of modern times was to be seen at Alnwick Castle, as the fruit of his work. He regretted that Mr. Pollen had not applied to the South Kensington Museum for more specimens to hang upon the walls, for he was sure they would have been lent. After all, the South Kensington Museum was one of the children of that Society, and they were always pleased to have an opportunity of showing honour and respect to their parent, the Society of Arts, which initiated the Exhibition of 1851, and had supported every movement connected with instruction throughout the kingdom.

Colonel Donnelly said he had come to learn and not to teach, and he certainly was not prepared to enter at a moment's notice on the large subject of wood-carving generally, but he might say a word or two about the school which had been alluded to as one of the means by which the art might have a chance of revival. He spoke, of course, of wood-carving in the architectonic sense, not as developed in some of the beautiful specimens exhibited, which might be looked upon more in the light of pictures than as accessory decorations. The school was really established with the aid of the City companies, and fortunately they had rooms lent them by the Royal Commissioners for the Exhibition of 1851. This school had been a striking example of the difficulties which were met with in attempting to found technical education, by which he meant, not general or special science or art-teaching, which might be useful in any particular branch of art or industry, but the absolute learning of the *technique* of the art. If you attempted to teach the *technique* of an art or trade in existence, those whom you taught could not get employment in the trade; they had not been entered in it, and it was almost impossible for them to get into it. If, on the other hand, you took up an art which had nearly died out, with a view to its revival, you found it very difficult to get pupils, because they naturally asked, "Shall we be able to find employment for our art when we have learned it?" On the other hand, those who might employ them did not design for wood-carving, because the art having died out, there was nowhere where they could get it done in the quantity and with the rapidity necessary in carrying out large business operations. This was really one of the great difficulties in the way, which would only be got over in time, but he hoped that some architects, who were now designing Queen Anne mansions by the hundred, would remember the School, and give them some orders. They were getting into a state in which a good deal of really good work might be carried out, though they could not undertake very large orders at present, but if they were encouraged, they would soon get more pupils, who would see their way to

an occupation in life. One great advantage was an art which ladies could follow, and as skilful in as men. They must, however, have artistic feeling, and must first learn draughtsmanship. It was not to be taken up by therefore, and when persons had learned draughtsmanship had some art appreciation, they did not know wood-carving was an occupation by which to earn their bread. If the work was to progress be with the co-operation of architects; but thank Mr. Pollen for the opportunity he had advertised the schools, and perhaps if some of the papers would be kind enough to abuse them would also further assist them.

Mr. Rogers said it seemed to have been at some time past that the art of wood-carving was a lost art, but he could not agree to this large proportion of the wood-carvers in England especially in London, had not for many years employment; he might safely say that on them had been out of employment three months for some time past. It was a lost art because it was not looked for. If the work had described had been inquired for during the years, it could be had. He saw men there, who he knew, though he might not have spoken of themselves, capable men, who had not been employed. He first heard the statement about five years ago, since when it seemed to have been in the public mind, and he was glad to have an opportunity of correcting it. He believed from an article in the *Builder*, stating that an architect wanted to get some work done in wood and could not get it done there, and had to go to Paris. A great deal was made of this time, but the gentleman explained afterwards that the trade just then happened to be very busy with work, which was wanted in a hurry, could not wait in time, but he had all he could execute in time, and he was much better pleased with the English than the French. These explanations, however, very often not seen by those who saw the statements, and so it got about that work could not be done in England. He did not believe, however, that an architect would say so. There was a great dearth of furniture being made which was never in the public. Customers would order things on their own taste, or from a design by their architect, and, as soon as it was done, it was sent home, and, therefore, there was no opportunity of judging of it by the general public. When acting, in connection with Mr. Donaldson at the recent Exhibition, he had a letter from Mr. Aumonier, saying he had some fine things in completion, but he could not spare them for some time; and asking if he might be allowed to take a piece for a fortnight, and then take it away and keep his work before the public. He was not permitted; but it struck him that some suitable place in London could be found for carvings, as they were finished, could be sent there a few days before they were sent home, and he might be better able to judge of the real position of the art. He had been much pleased with the paper, and he would like to move a vote of thanks to Mr. Pollen.

Mr. Mansfield thought Mr. Rogers's remarks were worthy of consideration; and he could extend by his own experience. A short time ago, he had some fine pieces of furniture in the warehouse, and by chance Mr. Graham and Mr. Donaldson came in, and saw them; they asked if they might have some workmen to see them, to which he readily assented. The first night 300 men came; many of them were pleased that they asked if they might come the next night and bring their friends; and on the following evening more than 1,000 came. He would

and that kind of thing if he could, even to opening a place on a Sunday. It was certainly to be regretted that things were passed out of hand so rapidly, that the evening classes had no opportunity of seeing what was done. His opinion was, that as good work could be done now as ever, if it were ordered.

Mr. Waldenroth referred to the fact that many wood-carvers had been thrown out of employment by the abandonment of carved work on carriages. The want of exhibiting good work for a short time was a great loss, because manufacturers did not care to make specially for exhibitions where they were locked up for months and perhaps not disposed of at all. He had seen in the manufacturer's shop, a few days before the Vienna and Paris Exhibitions, and was

Mr. Mackay said he was a member of the Wood-carvers' Society, and knew something about the subject. His fellow members of the trade were much interested to find this subject engaging the attention of the Society, and of the gentleman who had read the paper. There were points in it with which he could not by any means agree. There was a disparaging tone in it, he doubted very much if those practically acquainted with the subject would endorse. No doubt wood-carving had passed through several phases in the last forty years. In 1851, there were few faults; in the Paris Exhibition of 1857, the English Exhibition of 1862, there was ground for the better; and in 1878 it found its place, which it had not done before. Mr. Pollen, in token of sideboard carvings being overloaded with ornament and so on; but they did not see such things and he did not think the improvement had been upon as it deserved. As to the idea of the art being lost, and that it was only to be revived by this which was directed by Signor Bulletti, he disagreed from that altogether; there was a lot of life in it; and he failed to see how Signor Bulletti, with all his life, and all the influence he had to back him, was to revive it. Nor were the works exhibited last year at South Kensington such as would warrant those who produced them, and their friends, in believing it must mean that or nothing—that they would be able to gain anything like a subsistence. He thought if they were going on the wrong road, which would only lead to disappointment. His feeling was that although help could be given out of doors, and all instruction could be afforded in schools, the workmen must remain in the workshop. It was there that the man or boy could be trained to be a workman. As to the other sex, with all due respect to the Society, he believed that, except as a pastime, it was a mistake for anyone to advise them to take up a remunerative employment. No doubt workmen were not so advanced as they should be, but if they did so much, architects must come to their assistance, and do what they wanted, and give them directions. An architect would put up with sham and shoddy, but the wood-carver would also, and the workman had to walk round, or to produce that for which he had a disrepute which did no credit to him, and brought the art into disrepute.

Mr. Sandilands (secretary of the Wood-carvers' Society) said there were several present who could speak as to the present state of wood-carvers than of wood-carving. When he heard of this lecture, he wrote to the Secretary of the Society, who kindly sent him six copies, but if he had sent him one hundred, he could read them all, and have brought that number of who could have spoken feelingly as to the present state of wood-carvers. It seemed to have got to be that the wood-carver was almost an extinct trade, and that the art had to be revived by some

means or other, and that this school at South Kensington was to be one means of doing it. Colonel Donnelly thought that if the school was abused a little, it might be to its advantage, and he could assist him with any amount of abuse; but if that was the object of reviving wood-carving, it was not one which wood-carvers would want to assist. If it was to compete with the profession, and to invite architects and manufacturers to send work to it to be done by the students, and young men, who had little or no pay, how was it possible that men established in business, who had to pay liberal wages to their workmen, could compete with them—supposing that they were able to do the work—which remained to be seen. There were any amount of wood-carvers equal to any work which could be entrusted to them, but they could not stand alone, like painters, or sculptors; wood-carving was an accessory art, which depended on architects and designers for its existence. He would undertake to say that any number of men could be found in London to carry out all the work which was required, and if that was not the case at that moment, more would soon come forward. When work was wanted, it had always been found that men soon qualified themselves to accomplish it. The Houses of Parliament had been alluded to as showing unsatisfactory work; but it must be remembered that when they were built, that kind of work was very little known; but, at the present time, any quantity of it could be done equal to anything to be seen in old examples.

Mr. Pollen said very possibly he had failed to make himself fully understood as he had intended. He started by referring to several specimens of fine work, and said that the best work could be done to-day, as good as that of the old Venetians and Florentines—there were examples in that room, only just completed, as fine as anything Grinling Gibbons did. His point was not that it was a dead art in that respect, but he asked the question as a matter of fact—how much wood-carving did you see in modern Queen Anne houses? There were all sorts of cornices and ornaments, but they were all mouldings. He built a house himself, not long ago, and the first thing which occurred to him was, to have the ledges and styles of a pair of mahogany folding-doors carved. He obtained estimates; and he had specimens in his hand, the price of which was 2s., 1s. 9d., and 1s. 6d. a foot. If he had had the doors carved in that way, it would have added £10 or £15 to the price, which hardly any one could afford. Wood-carving was practically a lost art in that sense, that the price at which you could get it done was prohibitive—it was out of everybody's reach. What was wanted was a simpler style of thing, which an architect could order 500 or 600 feet of at a moderate price. The fine specimens referred to were, he believed, only turned out by very large firms. As to the school, he had only referred to some of the specimens as having been produced by it. He believed it was not started by Signor Bulletti, but by Colonel Donnelly. His object was to train people to common-place ground-work; so that if there was a demand for it, it could be had.

The Chairman, in moving the vote of thanks to Mr. Pollen, said they might congratulate themselves that there had been several members of the Wood-carvers' Society present, and he wished there had been, not six, nor sixty, but a hundred and sixty. He hoped there would be another paper on the same subject, when the members of the Wood-carvers' Society would come in a body. But however those who were present might dissent from certain remarks made by the lecturer, they would, at all events, acknowledge his kindness in coming forward and drawing attention to the subject, and he trusted they would so prepare themselves for a future occasion, as to really benefit the public. To that end, he would announce that any number of copies of the Journal containing the

arrangements for the purchase of land and erection of a building; but as these were set out eventually, it seems needless to repeat. The last paragraph of this report ran as follows:—"Lastly, it is proposed that the hall be commenced as soon as possible, Committee of Management, consisting of members appointed by the Royal Commission for the Exhibition of 1851, two members elected by the Council of the Royal Albert Society, and three members appointed by the Council of the Society of Arts." The Sub-Committee were to prepare plans and estimates.

Next, perhaps, necessary to refer in detail to the way in which preparations were made for the foundation of the school. It may be sufficient to say that eventually Mr. Charles J. Freaكه erected the school at his own cost. This was announced by the Prince of Wales at a meeting of the promoters, held at Marlborough House on the 9th of July, 1875. The Commissioners provided the site, near the Albert Hall, and the corporation of the Albert Hall provided to lend certain of the rooms, and a hall, for the use of the students. On the 12th of December, 1873, the first stone of the building was laid by H.R.H. the Duke of Albany. This event was celebrated by a concert at the Albert Hall, at which his Royal Highness presided. After referring briefly to the early stages of the negotiations, he said, "There was a long and arduous labours of the Society of Arts, and our efforts have now extended over about 15 years; there was another pause, which occurred on the suggestion, on account of a thought on the part of the two institutions might have been of no use. I myself undertook negotiations with the Royal Academy of Music with that view; some considerable time had been spent, but we found that the principles on which the two institutions were founded were so far apart, as not to be advisable that they should be united. The Royal Academy has but few scholarships for those who have displayed a high natural aptitude, but have not means; the fundamental principle of the school we are assembling to celebrate the foundation of, is to provide scholarships for all ranks of society." The school was opened, in 1876, with 82 free places, of which four were founded by the Society of Arts, two by members of the Society of Arts, and by Mrs. Freaكه, ten by the Corporation of London, fourteen by some of the City Guilds, and six by provincial towns, nearly all of which were obtained through the agency of the Society of Arts, the money for the purpose being provided by the understanding that, so soon as the school was able to afford it, the cost of these scholarships should be refunded to the Society.

The objects for which this school was founded are set forth in the report above referred to, issued by the Musical Committee in 1873. This report was issued as a draft prospectus for the time, and the substance of it was in the first Directory issued by the school. In that Directory it was stated that "the fundamental and primary object of the school is the education of the highest musical aptitude

in the country, in whatever station of society it may be found. In order to carry out this principle to the fullest extent, admission to the school will be obtained by competitive examination alone. A Training School for Music founded thus, on the basis of free instruction, given only to successful competitors in public examinations, occupies a field of action wholly distinct from that of any existing institution."

8. The amount spent previous to the foundation of the National Training School for Music, by the Musical Educational Committee, was £217. Since the foundation of the school, in 1873, there has been spent £956, exclusive of the Society's Scholarships, which amount to £800. The Society has also held examinations in Music since 1859, in connection with its general system of examinations. The charges of these cannot well be separated from the General Examination charges. The fees for the Examiners in Music, however, amount to £214, while £194 have been paid for prizes. The total amount which the Society may be said to have expended upon Musical Education, and the National Training School for Music, is £2,382, of which £1,758 have been spent directly upon the school, during the past seven years.

## MISCELLANEOUS.

### ROSE OIL, OR OTTO OF ROSES.

By Charles G. Warnford Lock.

This celebrated perfume is the volatile essential oil distilled from the flowers of some varieties of rose. The botany of roses appears to be in a transition and somewhat unsatisfactory state. Thus the otto-yielding rose is variously styled *Rosa damascena*, *R. sempervirens*, *R. moschata*, *R. gallica*, *R. centifolia*, *R. provincialis*. It is pretty generally agreed that the kind grown for its otto in Bulgaria in the damask rose (*R. damascena*), a variety induced by long cultivation, as it is not to be found wild. It forms a bush, usually 3 to 4 feet, but sometimes 6 feet high; its flowers are of moderate size, semi-double, and arranged several on a branch, though not in clusters or bunches. In colour, they are mostly light-red; some few are white, and said to be less productive of otto.

The utilisation of the delicious perfume of the rose was attempted, with more or less success, long prior to the comparatively modern process of distilling its essential oil. The early methods chiefly in vogue were the distillation of rose-water, and the infusion of roses in olive oil, the latter flourishing in Europe generally down to the last century, and surviving at the present day in the South of France. The butyrous oil produced by the distillation of roses for making rose-water in this country is valueless as a perfume; and the real otto was scarcely known in British commerce before the present century.

The profitable cultivation of roses for the preparation of otto is limited chiefly by climatic conditions. The odoriferous constituent of the otto is a liquid containing oxygen, the solid hydrocarbon or stearoptene, with which it is combined, being absolutely devoid of perfume. The proportion which this inodorous solid constituent bears to the liquid perfume in-

\* See Minutes of Council, 10th May, 1874.

creases with the unsuitability of the climate, varying from about 18 per cent. in Bulgarian oil, to 35, and even 68 per cent. in rose oils distilled in France and England. This increase in the proportion of stearoptene is also shown by the progressively heightened fusing-point of rose oils from different sources: thus, while Bulgarian oil fuses at about 61° to 64° Fahr., an Indian sample required 68° Fahr.; one from the South of France, 70° to 73° Fahr.; one from Paris, 84° Fahr.; and one obtained in making rose-water in London, 86° to 89½° Fahr. Even in the Bulgarian oil, a notable difference is observed between that produced on the hills, and that from the lowlands.

It is, therefore, not surprising that the culture of roses, and extraction of their perfume, should have originated in the East. Persia produced rose-water at an early date, and the town of Nisibin, north-west of Mosul, was famous for it in the 16th century. Shiraz, in the 17th century, prepared both rose-water and otto, for export to other parts of Persia, as well as all over India. The Perso-Indian trade in rose oil, which continued to possess considerable importance in the third quarter of the 18th century, is declining, and has nearly disappeared; but the shipments of rose-water still maintain a respectable figure. The value, in rupees, of the exports of rose-water from Bushire in 1879, were—4,000 to India, 1,500 to Java, 200 to Aden and the Red Sea, 1,000 to Muscat and Dependencies, 200 to Arab coast of Persian Gulf, and Bahrein, 200 to Persian coast and Mekran, and 1,000 to Zanzibar. Similar statistics relating to Lingah, in the same year, show—Otto: 400 to Arab coast of Persian Gulf, and Bahrein; and 250 to Persian coast and Mekran. And Bahrein—Persian Otto: 2,200 to Koweit, Busrah, and Bagdad; rose-water: 200 to Arab coast of Persian Gulf, and 1,000 to Koweit, Busrah, and Bagdad.

India itself has a considerable area devoted to rose-gardens, as at Ghazipur, Lahore, Amritzur, and other places, the kind of rose being *R. damascena*, according to Brandis. Both rose-water and otto are produced. The flowers are distilled with double their weight of water in clay stills; the rose-water (*goolabi pani*) thus obtained is placed in shallow vessels, covered with moist muslin to keep out dust and flies, and exposed all night to the cool air, or fanned. In the morning, the film of oil, which has collected on the top, is skimmed off by a feather, and transferred to a small phial. This is repeated for several nights, till almost the whole of the oil has separated. The quantity of the product varies much, and three different authorities give the following figures:—(a) 20,000 roses to make 1 rupee's weight (176 gr.) of otto; (b) 200,000 to make the same weight; (c) 1,000 roses afford less than 2 gr. of otto. The colour ranges from green to bright-amber, and reddish. The oil (otto) is most carefully bottled; the receptacles are hermetically sealed with wax, and exposed to the full glare of the sun for several days. Rose-water deprived of otto is esteemed much inferior to that which has not been so treated. When bottled, it is also exposed to the sun for a fortnight at least.

The Mediterranean countries of Africa enter but feebly into this industry, and it is a little remarkable that the French have not cultivated it in Algeria. Egypt's demand for rose-water and rose-vinegar is supplied from Medinet Fayum, south-west of Cairo. Tunis has also some local reputation for similar products. Von Maltzan says that the rose there grown for otto is the dog-rose (*R. canina*), and that it is extremely fragrant, 20 lbs. of the flowers yielding about 1 dr. of otto. Genoa occasionally imports a little of this product, which is of excellent quality. In the south of France, rose gardens occupy a large share of attention, about Grasse, Cannes, and Nice; they chiefly produce rose-water, much of which is exported to England. The essence (otto) obtained by the distillation of the Provence rose (*R. provincialis*) has a characteristic perfume, arising, it is believed, from the bees transporting the pollen of the

orange flowers into the petals of the roses. The otto is richer in stearoptene than the nine grammes crystallising in a litre (1½ pint) at the same temperature as 18 grammes of the The best preparations are made at Cannes. The flowers are not there treated for the otto submitted to a process of maceration in fat kilos. of roses being required to impregnate fat. The price of the roses varies from 50 25 c. per kilo.

But the one commercially important source roses is a circumscribed patch of ancient modern Bulgaria, stretching along the south of the central Balkans, and approximately between the 25th and 26th degrees of east and the 42nd and 43rd degrees of north latitude. chief rose-growing districts are Philippopoli, Gioupeu, Karadshah-Dagh, Kojum-Tepe, Jeni-Sara, Bazardshik, and the centre and head of the industry, Kazanlik (Kisanlik), situated beautiful undulating plain, in the valley of the The productiveness of the last-mentioned district is judged from the fact that, of the 123 localities carrying on the preparation of otto they numbered 140 in 1859—42 belong to it. place affording otto on the northern side of it is Travina. The geological formation there is syenite, the decomposition of which has proved so fertile as to need but little manuring. The tion, according to Baur, indicates a climate but slightly from that of the Black Forest, the summer temperatures being stated at 82° Fahr. and 68° Fahr. in the evening. The rose-bush best and live longest on sandy, sun-exposed south-east aspect slopes. The flowers produced growing on inclined ground are dearer as esteemed than any raised on level land, being richer in oil, and that of a stronger quality proves the advantage of thorough drainage. On the other hand, plantations at high altitudes yield which is of a character that readily congeals, insufficiency of summer heat. The districts adjacent to and in the mountains are sometime hard frosts, which destroy or greatly reduce. Floods also occasionally do considerable damage bushes are attacked at intervals and in pale blight similar to that which injures the country.

The bushes are planted in hedge-like rows and fields, at convenient distances apart, for the crop. They are seldom manured, planting takes place in spring and autumn; attain perfection in April and May, and then from May till the beginning of June. The flowers are gathered before sunrise, often with attached; such as are not required for immediate distillation are spread out in cellars, but all within the day on which they are plucked. That, if the buds develop slowly, by reason of damp weather, and are not much exposed to sun when about to be collected, a rich yield of otto at a low solidifying point, is the result, whereas a sky be clear and the temperature high at or before the time of gathering, the product is less and is more easily congealable. Hanbury, contrary, when distilling roses in London, when they had been collected on fine dry days, water had most volatile oil floating upon it when gathered in cool rainy weather, little oil separated.

The flowers are not salted, nor are any other treatment, before being conveyed on the heads of men and women, and animals, to the distilling apparatus. The otto is collected in a tin of copper, erected on a brick, and heated by a wood fire; from the straight tin pipe, which obliquely descends

ntly filled with cold water, by a spout, from nient rivulet, and constitutes the condenser. h stills are usually placed together, often shade of a large tree. The still is charged 50 lbs. of roses, not previously deprived of es, and double the volume of spring water. ation is carried on for about  $1\frac{1}{2}$  hour, the g simply a very oily rose-water (*ghyul-suyu*). sted flowers are removed from the still, and m is used for the next distillation, instead of r. The first distillates from each apparatus and distilled by themselves, one-sixth being ; the residue replaces spring water for sub- tations. The distillate is received in long- sles, holding about  $1\frac{1}{2}$  gallon. It is kept in a day or two, at a temperature exceeding by which time, most of the oil, fluid and have reached the surface. It is skimmed off long-handled, fine-orificed tin funnel, and is for sale. The last-run rose-water is extremely ud is much prized locally for culinary al purposes. The quantity and quality of : much influenced by the character of the n distilling. When hard spring water is he otto is rich in stearoptene, but less and fragrant. The average quantity of is estimated by Baur at 0.037 to 0.040 per er authority says that 3,200 kilos. of roses of oil.

carefully distilled, is at first colourless, becomes yellowish; its specific gravity is Fahr.; its boiling-point is  $441^{\circ}$  Fahr.; it  $18^{\circ}$  to  $60\text{--}8^{\circ}$  Fahr., or still higher; it is soluble lcohol, and in acetic acid. The most usual tests of the quality of an otto are (1) its e congealing point, (3) its crystallisation. m be judged only after long experience. should congeal well in five minutes at a of  $34\text{--}5^{\circ}$  Fahr.; fraudulent additions ongealing point. The crystals of rose- re light, feathery, shining plates, filling uid. Almost the only material used for eighening the apparent proportion of a said to be spermaceti, which is easily from its liability to settle down in a solid om its melting at  $122^{\circ}$  Fahr., whereas uses at  $91\text{--}4^{\circ}$  Fahr. Possibly paraffin wax asily escape detection.

rations by means of other essential oils are difficult of discovery, and much more act, it is said that none of the Bulgarian letely free from this kind of sophistic- e oils employed for the purpose are e grass oils (*Andropogon* and *Cymbopogon* r that afforded by *Andropogon*, *Schananthus yki* by the Turks, and commonly known to s "geranium oil," though quite distinct eranium oil. The addition is generally rinking it upon the rose-leaves before t is largely produced in the neighbourhood . exported to Turkey by way of Arabia; it rabs in Constantinople in large bladder- d-copper vessels, holding about 120 lbs. ly itself adulterated with some fatty oil, it lergo purification before use. This is e following manner:—The crude oil is aken up with water acidulated with lemon- hich it is poured off after standing for a shed oil is placed in shallow saucers, well a and air, by which it gradually loses its odour. Spring and early summer are the for the operation, which occupies two to cording to the state of the weather and f the oil. The general characters of this alar to those of otto of roses—even the g a distant resemblance—that their dis- then mixed is a matter of practical im-

possibility. The ratio of the adulteration varies from a small figure up to 80 or 90 per cent. The only safe-guard against deception is to pay a fair price, and to deal with firms of good repute, such as Messrs. Papasoglu, Manoglu and Son, Ihmsen and Co., and Holstein and Co., in Constantinople.

The otto is put up in squat-shaped flasks of tinned copper, called *kunkumars*, holding from 1 to 10 lb., and sewn up in white woollen cloths. Usually their contents are transferred at Constantinople into small gilded bottles of German manufacture for export. The Bulgarian otto harvest, during the five years 1867-71, was reckoned to averagesomewhat below 400,000 *meticals*, *miskals*, or *midkals* (of about 3 dwt. troy), or 4,226 lb. av.; that of 1873, which was good, was estimated at 500,000, value about 700,000*l.* The harvest of 1880 realised more than 1,000,000*l.*, though the roses themselves were not so valuable as in 1876. About 300,000 *meticals* of otto, valued at 932,077*l.*, were exported in 1876 from Philippopolis, chiefly to France, Australia, America, and Germany.

#### PROVINCE OF ASTERABAD AND ITS INHABITANTS.

Asterabad is situated in the south-east corner of the Caspian Sea; its inhabitants do not exceed 45,000, and the town of Asterabad can only boast of 8,000 souls. It is bounded on the south by the high range of mountains which separate the Persian Caspian provinces from the other parts of Persia. On the north it is bounded by the Atrek as far as Chat, situated at the confluence of the Sombar and the Atrek; beyond that point it is doubtful where the boundary lies in that direction. The west is bounded by the Caspian Sea and the province of Mazanderan, and in the east it is adjoining to the province of Meshed. Gez, Molla, Kelle, and Gumush Tèpè are the only ports in the province in use. The former is in weekly communication with the other ports of the Caspian by means of the Mercury and Kafkas steamers, and although but a small village of 150 houses, it is the emporium of all the trade carried on between the civilised world and north-east Persia. English manufactures, French sugar, and Russian hardware find their way through Gez to Meshed and Herat, while Yezd opium, Meshed carpets, Sebzewar silkworm eggs, Damghan lead, Asterabad cotton and wheat find an outlet through Gez. The province of Asterabad is well wooded, and is watered by numerous mountain streams. The principal districts are those of Anazan, Sedem, Rustak, Asterabad Rustak, Katoul, Finderisk, Shahkou, and Salwar. The inhabitants of Asterabad mostly belong to the Kajar tribe, of which the Shah of Persia is the chief; members of the Tat tribes are also to be met with. As head of the Kajars, the Shah possesses considerable estates in the province, which are farmed out to various individuals, giving a rental of £7,700. The fertility of the soil, wherever it has been cleared of the overhanging forest, is wonderful, producing as much as from 60 to 120 bushels for one bushel sown. The timber in the forests is magnificent, and in any other country it would form a source of great riches, but over the whole extent of the province there is not a single road worthy of that name, and the traffic that penetrates into the interior has to wend its way on horseback through the forests and through the rice fields.

Parallel with the Elboorz, and at a distance of 20 miles to the north, runs the river Gurgan, about 60 miles long. Fifteen miles or so north of the Gurgan is the Atrek. Between these two rivers is to be found the most fertile soil that can possibly be imagined, and it is on this strip of land that the Turkomans pitch their oahs; the Yemoots between the sea shore and Gombuz-i-Kabous, 60 miles inland; and the Goklans between this point and Kari-Kaleh. The Yemoot tribe of

Turkomans number about 80,000 families, of which, however, only about 20,000 have anything to do with Persia. They are sub-divided into two distinct tribes, named, respectively, Jaaserbai or Sherif, and Attabai, or Chuni. The Jaaserbai Turkomans comprise two grand divisions—the Yar Alis, and the Noor Alis, each having various sub-divisions of its own. The Attabai Turkomans have also two grand divisions—the Attabai proper, and the Ak. Each of these divisions comprise two classes of Turkomans, called respectively, Charvai, and Chumour, that is to say the rich or noble class, which can afford to move about from place to place, and the poorer class, called Chumour, whose means do not enable them to move away from the banks of the Gurgan. The Charvai are in the habit of moving towards the north, as far as the Balkan mountains, near Krasnovodak, twice a year. When the harvest is ripe, these nomads return to the Gurgan. The Chumour are the people, generally speaking, who are addicted to man stealing. The amount of tribute paid by the Yemoot Turkomans to the Persian Treasury is 2,000 tomans; it is collected both in money and kind, such as carpets and felts. Advantage is frequently taken by the Persian authorities, of any discord reigning among the Turkomans themselves to increase the amount of taxation, and the Turkomans seize the first opportunity to recoup themselves on the villagers of Asterabad. The Goklans were formally 12,000 families, but owing to the constant attacks made upon them by their Persian neighbours, the Saad-el-Loo Kurds of Boojnoord, they have now been reduced to 4,000. They inhabit the rich plains, situated on either side of the Gurgan, east of Gombuzi-Kabous. The amount of tribute paid by the Goklans to the Treasury is 6,000 tomans, which is collected by Yar Mohammed Khan, of Boojnoord, and handed over to the Government of Asterabad.

Besides the regular caravans, a large number of pilgrims pass through the province of Asterabad every year from the western shores of the Caspian Sea, proceeding to the Holy Shrine of Reza, the seventh Imam of the Shias, whose tomb is in the city of Meshed, in Khorassan, and to defray the expenses of the journey, the pilgrims usually carry with them small parcels of merchandise; by this means the produce and industry of Russia and the Caucasus, and even of Western Europe, finds its way up to the confines of Afghanistan, while the produce of Central Asia, in the shape of carpets, coarse cloth, felt, lamb skins, dried fruit, and precious stones, finds its way to the markets of Western Asia and Constantinople.

### CINCHONA BARK FROM JAMAICA.

A large consignment of Cinchona bark from Jamaica has, during the past few months, found its way into the London market, where it has met with a ready sale, and at prices far in advance of those realised for Ceylon and East Indian bark. The results of the Jamaica Cinchona sales for the year 1879-80, have, according to the report of the Director of Public Gardens and Plantations, slightly exceeded the estimated returns, and are as follows:—Quantity of bark shipped, 27,399 lbs.; gross amount realised, £5,380 9s. 6d., nett sum realised, £5,146 8s. 7d. It is shown in the report just referred to, that crown bark realises the highest price, and the greater value of this being established as against red bark, it is found desirable to plant the red bark only at elevations (2,500 to 4,000 feet) where the crown bark will not grow. The latter, however, may be cultivated in Jamaica over thousands of acres on the Blue Mountain slopes, on all elevations above 4,000 feet. The following quotations of prices will show the comparison between Ceylon and Jamaica barks. For red bark "fine quill," from Ceylon, reached a maximum of 4s. 3d. per lb., as against 4s., for "fair quill," from

Jamaica. For "red root bark," the highest Jamaica produce was 4s. 8d. per lb., for "good root," from Ceylon, as against 2s. 6d. for "good root," from Ceylon, showing an advantage in favour of Jamaica to the extent of 2s. 2d. per lb. For "twig ordinary" bark of *Cinchona succirubra*, Ceylon obtained from 2½d. to 1s. per lb. as against 1s. 6d. per lb. for similar bark from Jamaica. "I will, it is hoped, show that as with the celebrated Mountain coffee of Jamaica, so with the Cinchona grown in the same region, the conditions of climate appear to be eminently favourable to the production of the best qualities of these valuable, and as large tracts of land and the necessary labour is now available, there are only wanting sufficient capital and energy to overcome the initial difficulties of enterprise."

Accompanying the report from whence the extracts are a series of instructions under the title "Hints and suggestions for raising Cinchona from seed and establishing Cinchona plantations."

### CORRESPONDENCE.

#### MACTEAR'S MECHANICAL FURNACE CONTINUOUS SYSTEM OF MANUFACTURE OF SULPHATE OF SODA.

Referring to the report of Mr. Mactear's paper on this subject in the *Journal* of February 4, 1880, our patents having been alluded to in a very distant manner, we rely upon your sense of fairness in making a few brief corrections to go forth to you through the same medium, viz.:—

1. We beg to point out that our first patent is not restricted to any particular form of apparatus, but covers the principle of conducting the calcination and decomposition in the same vessel by means of a rotating pan.

2. In this patent Mr. Mactear sees not the "failure." As a matter of fact, although not patented by our improved pattern of 1880 date, it is from 25 to 30 furnaces, on the original plan, in operation, the returns from which continue to be satisfactory.

3. Mr. Mactear states that the "greatest objection to the system adopted by Jones and Williams which holds good equally with the new form of apparatus is that the salt and acid, being all added within a comparatively small period of time, there is a generation of muriatic acid gas at the beginning of the operation, and a rapidly decreasing amount as the operation continues." This objection is purely theoretical; in practice, it is found that with proper arrangements, there is no difficulty whatever in condensing the muriatic acid gas, the fact being, as stated by Mr. Mactear, that more hydrochloric acid, and of a higher concentration, is obtained from our patent furnace than from ordinary hand furnaces.

4. There is nothing new in the "continuous" system adopted by Mr. Mactear. At the suggestion of Hugh Lee Pattinson, of Newcastle, it was first tried in 1876; the apparatus for the purpose was operated by a ratchet wheel, as described by Mr. Mactear, and was provisionally adopted by the engineer who made it. It was abandoned, but the apparatus is in our hands.

5. We deny that our rotating furnace (patent) is in any respect an "imitation" of Mactear's rotating furnace. It was merely a return to our original plan, tried in 1876, of which we have the patent. The principle of a rotating pan is old, much of it either Mr. Mactear's or our own ideas on the subject.

JONES & W.

### MEANS FOR PREVENTING LONDON SMOKE.

condemnation of Mr. J. A. C. Hay's letter, beg to be allowed to refute the statements Scott-Moncrieff's paper, in so far as they relate to the Royal Arsenal or any other of the Government works." He then proceeds to confirm my statement in every detail and particular. I alleged in difficulties, the manager of the gas works at the Arsenal had used a short extraction. Mr. Scott-Moncrieff states that the fuel was superior. Mr. Hay confirms this by stating that the coal they used was volatile cannel, and that the extraction "it contained very little heat, and was not used under the retorts." Hay means to say the fuel was worse under a short extraction than a long one? If so, he contradicts what I made to me by Mr. Wallace, who said it was better. Does Mr. Hay mean to deny that gas comes off during the first two or three minutes? Does he deny that it comes off chiefly during that period? In short, does he deny what he himself confirms, by his own statement, and "in order to meet a few emergencies," adopted the scheme which I proposed in my paper? He speaks of the plan having been found to be very expensive and uneconomical, but Hay did not carry it out with sufficient inquiry, and his is hardly to be wondered at. As to Mr. Hay's postscript, as to whether he did or did not supply me with the facts, this is a question of personal veracity. I certainly understood the facts precisely as I stated them in my paper, and any conclusions which I drew from them are confirmed by Mr. Hay's own statement. I was aware of any official relations between Mr. Hay and Mr. Hay, nor, indeed, am I now aware of any relations.

W. D. SCOTT-MONCRIEFF.

### WOOD-CARVING.

reference to the discussion which took place last week it ought to be stated that the School of Carving at the Royal Albert-hall derives its support from some of the City Companies, and the Science and Art Department, as some of them seemed to imagine. I hope it will do good to the trade, as well as to the public.

J. H. POLLEN.

Age-crescent, W., Feb. 10, 1881.

### GENERAL NOTES.

**Art Wood-carving.**—This school is now in connection with the City of Guilds of London Technical Institute. It is under the direction of a committee of which Lieut.-Colonel J. P. D. Donnelly, M.P., is chairman. Day and evening classes are held in the school. The day classes are held from 10 to 5 on five days, and from 10 to 1 on Saturdays. The evening classes are held from 7 to 9 on four evenings a week, viz., Monday, Thursday, and Friday. The fees for day classes are 2s. a month, or 2s. a quarter. The fees for evening classes are 1s. a month, or 2s. a quarter. There are 12 free studentships in the school, viz., six in the day classes, and six in the evening classes, the fees for which are funded by the City and Guilds of London for the advancement of technical education. The studentships are selected by the committee

of the school from persons of the industrial class, who are intending to earn their living by wood-carving. Candidates must have passed the 2nd grade art examination of the Science and Art Department in freehand drawing at least. Those who have some knowledge of wood-carving, or have passed in the other subjects of the 2nd grade art certificate, or in drawing from the antique and the figure, architectural drawing, or designing, or in modelling, will be preferred. There are now several vacant studentships, and there is also available accommodation for a few additional paying students. Students who have been in the school not less than twelve months may, on the recommendation of the inspector, receive such payment for their work as the committee may determine. By permission of the Lord President of the Council, students of the school have the privilege of free admission to the South Kensington Museum and libraries, on production of their school tickets. Wood-carving for the trade is undertaken by the school. For further information on all the above points, applications should be addressed to the secretary at the school.

**Domestic Sanitation.**—Dr. Richardson's course of nine lectures, to be delivered before the Ladies' Sanitary Association, in the Hall of the Society of Arts, will commence on Saturday, 12th inst., at 5.30 p.m., and be continued on successive Saturdays, until April 8. Tickets admitting to reserved seats, one guinea for the course, or 3s. 6d. for each lecture, can be obtained at the office of the Association, 22, Brompton-street, W., or at the Society of Arts. Admission to unreserved sittings, 1s.

### MEETINGS OF THE SOCIETY.

#### ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

FEBRUARY 16.—"The Participation of Labour in the Profits of Enterprise." By SEDLEY TAYLOR, M.A., late Fellow of Trinity College, Cambridge. W. H. HALL will preside.

FEBRUARY 23.—

MARCH 2.—"On Lighthouse Characteristics." By Sir WILLIAM THOMSON, LL.D., F.R.S. F. J. BRAMWELL, F.R.S., Chairman of Council, will preside.

MARCH 9.—

MARCH 16.—"Buying and Selling; its Nature and its Tools." By Prof. DONAMY PRICE, M.A. Lord ALFRED S. CHURCHILL will preside.

MARCH 23.—"The Increasing Number of Deaths from Explosions, with an Examination of the Causes." By CORNELIUS WALFORD.

MARCH 30.—"Recent Advances in Electric Lighting." By W. H. FREER.

APRIL 6.—"The Manufacture of Glass for Decorative Purposes." By H. J. POWELL (Whitefriars Glass Works).

#### FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

FEBRUARY 22.—"The Languages of South Africa." By ROBERT N. COVE.

MARCH 15.—"The Loo Choo Islands." By Consul JOHN A. GURBINS. Sir RUTHERFORD ALCOCK, K.C.B., will preside.

APRIL 5.—"Trade Relations between Great Britain and her Dependencies." By WILLIAM WHISTART.

#### APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

FEBRUARY 24.—"Deep Sea Investigation, and the Apparatus used in it." By J. G. BUCHANAN, F.R.S.E., F.C.S. Captain Sir GEORGE S. NARES, R.N., K.C.B., F.R.S., will preside.

**MARCH 24.**—"The Future Development of Electrical Appliances." By Prof. JOHN PERRY.

The meeting previously announced for April 7 will be held on May 12.

### INDIAN SECTION.

Friday evenings, at eight o'clock:—

**FEBRUARY 11.**—"Gold in India." By HYDE CLARKE. Sir WILLIAM ROBINSON, K.C.S.I., will preside.

**MARCH 4.**—"The Results of British Rule in India." By J. M. MACLEAN.

**MARCH 25.**—"The Tenure and Cultivation of Land in India." By Sir GEORGE CAMPBELL, K.C.S.I., M.P.

**MAY 13.**—"Burmah." By General Sir ARTHUR PHAYRE, G.C.M.G., K.C.S.I., C.B.

Members are requested to notice that it may be necessary to make alterations in the dates of the above papers.

### CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Second Course will be on "Watchmaking," by EDWARD RICE, M.A. Three Lectures.

#### *Syllabus of the Course.*

#### LECTURE II.—FEBRUARY 14.

The ordinary watch—Degree of accuracy required in it—Systems of manufacture in this country and abroad—Description of specimens illustrative of the various stages of construction—Comparison of the several systems.

#### LECTURE III.—FEBRUARY 21.

Necessity of efforts to promote the art in this country—Need of education, theoretical and practical, in horology—Literature—Great want of uniformity in gauges, screws, &c.—Exhibition of ordinary and complicated watches, and of watchmakers' tools—Conclusion.

The Lectures will be illustrated by Specimens, Models, and Diagrams. The different movements, &c., will be shown enlarged on the screen by means of the Aphengiscope and the Electric Light.

The Third Course will be on "The Scientific Principles involved in Electric Lighting," by Prof. W. G. ADAMS, F.R.S. Four Lectures.

March 7, 14, 21, 28.

The Fourth Course will be on "The Art of Lace-making," by ALAN S. COLE. Three Lectures.

April 25; May 2, 9.

The Fifth Course will be on "Colour Blindness and its Influence upon Various Industries," by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

May 16, 23, 30.

### ADMISSION TO MEETINGS.

Members have the right of attending all the Society's meetings and lectures. Every Member can admit *two* friends to the Ordinary and Sectional Meetings, and *one* friend to the Cantor Lectures. Books of tickets for the purpose have been issued to the Members, but admission can also be obtained on the personal introduction of a Member.

### MEETINGS FOR THE ENSUING WEEK.

**MONDAY, FEB. 14TH.**—SOCIETY OF ARTS.

Adelphi, W.C., 8 p.m. (Cantor Lectures.)

Rigg, "Watchmaking" (Lecture II.)

Royal Institution, Albemarle-street, W., 8 p.m.

Hueffer, "The Troubadours" (Lecture I.)

Royal Geographical, University of London, gardens, W., 8 p.m.

Mr. William M. Croft, "Physical Aspects of Sarawak Borneo."

British Architects, 9, Conduit-street, W., 8 p.m.

Discussed on Mr. E. C. Robins' paper, "Science in its Relation to Civil Architecture."

Medical, 11, Chandos-street, W., 8 p.m.

London Institution, Finsbury-circus, E.C., 8 p.m.

John Lubbock, "Fruit and Seeds."

**TUESDAY, FEB. 15TH.**—Royal Institution, Albemarle-street, W.C., 8 p.m.

Prof. E. A. Schiffer, "The Blood."

Civil Engineers, 25, Great George-street, S.W., 8 p.m.

Discussed on the paper by Colson and Meyer, "The Portsmouth Dock Works."

Statistical, Somerset-house-terrace, Strand, W.C., 8 p.m.

Pathological, 53, Berners-street, Oxford-street, W., 8 p.m.

Zoological, 11, Hanover-square, W., 8 p.m.

Secretary, "Additions to the Society's Men's Club for the Month of January, 1881." 2. Mr. C. H. B. Distant, "The Coleopterous Insects of the Family Hissipidae, collected by Mr. Buckley."

3. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 4. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

5. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 6. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

7. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 8. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

9. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 10. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

11. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 12. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

13. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 14. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

15. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 16. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

17. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 18. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

19. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 20. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

21. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 22. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

23. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 24. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

25. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 26. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

27. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 28. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

29. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 30. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

31. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 32. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

33. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 34. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

35. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 36. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

37. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 38. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

39. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 40. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

41. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 42. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

43. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 44. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

45. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 46. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

47. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 48. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

49. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 50. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

51. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 52. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

53. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 54. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

55. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 56. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

57. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 58. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

59. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 60. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

61. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 62. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

63. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 64. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

65. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 66. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

67. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 68. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

69. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 70. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

71. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 72. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

73. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 74. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

75. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 76. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

77. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 78. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

79. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 80. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

81. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 82. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

83. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 84. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

85. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 86. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

87. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 88. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

89. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 90. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

91. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 92. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

93. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 94. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

95. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 96. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

97. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 98. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

99. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 100. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

101. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 102. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

103. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 104. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

105. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 106. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

107. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 108. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

109. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 110. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

111. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 112. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

113. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 114. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

115. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 116. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

117. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 118. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

119. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 120. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

121. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 122. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

123. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 124. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

125. Mr. W. L. Distant, "Additions to the Fauna of the Ethiopian Region." 126. Mr. Smith, "A Collection of Shells from Lake and Nyassa and Other Localities in East Africa."

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,474. VOL. XXIX.

FRIDAY, FEBRUARY 18, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## CANTOR LECTURES.

second lecture of the second course was read on Monday, 14th inst., by Edward Rigg, on "Watchmaking." The points to which attention was specially drawn, were the degree of accuracy required in the ordinary watch, the quality of manufacture in this country and abroad, and a comparison of the several systems. The lecture was illustrated by the use of the aphengium and the electric light, which enabled different parts of watches, and the works of several watches (going and not going) to be reflected on a screen. The audience were thus able to see the action of the object itself on an enlarged scale. Next time it is intended to show the action of repeating watches in the same manner.

A collection of specimens illustrative of the several stages of construction in the watch, which will be exhibited, will remain in the rooms of the Society for a week, and can be seen by anyone interested in the subject, on presentation of his ticket.

Lectures will be published in the *Journal* during the summer vacation.

## LABEL FOR PLANTS.

The Council are prepared to award a Society's Medal, together with a prize of £5, which may be placed at their disposal for the purpose of the competition. G. F. Wilson, F.R.S., for the best label for plants.

The object of the offer is to obtain a label which is cheap and durable, and may show legibly whether the name is written or printed thereon; the label must be suitable for plants in open border. The following considerations will principally govern the selection.

Specimen labels, bearing a number or motto, accompanied by a sealed envelope containing the name of the sender, must be sent in to the Secretary not later than the 1st May, 1881.

The Council reserve to themselves the right of withholding the Medal and Prize offered, if, in the opinion of the judges, none of the specimens sent in are deserving.

## ADJOURNMENT OF MEETING.

At the meeting of Wednesday, the 17th inst., the discussion on Mr. Sedley Taylor's paper, "The Participation of Labour in the Profits of Enterprise," was adjourned to Friday, the 25th inst., at 8 p.m. Cards already issued will be available for the adjourned meeting.

## DOMESTIC ECONOMY.

1. The Council will hold a Third Congress on Domestic Economy, at the Society's Rooms in the Adelphi, London, during the present year.

2. The Council offer Seven Bronze Medals, and Certificates of Merit for Papers (not exceeding 1,000 words), written by Teachers of Public Elementary Schools and Training Colleges, which shall give an account of the best method practised by the teacher, of the teacher's experience, and the result of the teaching, in any one or more of the seven classes of subjects named below.

3. The Education Department, in the Code of 1880 (p. 31), classes the following subjects under Domestic Economy for Girls:—

The First Branch includes—

- (a) Clothing and Washing.
- (b) The Dwelling—Warming, Cleaning, and Ventilation.
- (c) Rules for Health—The Management of the Sick Room, Cottage Income, Expenditure, and Savings.

The Second Branch includes—

- (a) Food—Its Composition and its Nutritive Value
- (b) Food—Its Functions.
- (c) Food—Its Preparation and Culinary Treatment (i.e., Practical Cookery) (§ 24).

The Council have resolved to add the subject of Needlework, which will be exhibited and discussed in the Congress, although it is not classed in the Code as a branch of Domestic Economy.

4. Only one medal will be given to a teacher, but the subjects taught successfully will be inscribed on the one medal and a certificate given.

5. The papers must be sent to the Secretary or the Society of Arts by the 1st May next. Each paper must be enclosed in a sealed envelope, bearing a motto, and must be accompanied by an envelope bearing the same motto, and having within it the writer's name and address.

6. No medals or certificates will be awarded if the papers are not of sufficient merit to deserve them.

## INDIAN SECTION.

Friday, February 11, 1881; Sir WILLIAM ROSE BENISON, K.C.S.I., in the chair.

The paper read was—

## GOLD IN INDIA.

By Hyde Clark.

I. It was originally intended that this paper should have been read before a general meeting of the Society, in which case it might have been treated in considerable detail, for popular explanation. This, however, is not suited for the audience of the Indian Section, acquainted to a great extent with the subject, and whose attention has already been called to its bearings. If, however, the mode of treatment be altered, the importance of the subject is none the less, if it be not indeed greater. It is of much moment to all interested in India to determine what is the real character of the gold formations, and what effect they are likely to have on the country.

In so dealing with the matter in its general relations, there will be this advantage, that the possibility of promoting any individual speculation will be eliminated.

That there will be speculation, and wild speculation, in the new undertakings, there is not room for any doubt, but that is not to be taken into account in the serious consideration. It is not the casualties, not the extraneous circumstances, which are to be mainly regarded, but the really essential conditions.

There is a prevalent sentiment in Indian circles, that it is necessary to be cautious in dealing with the gold question. It is necessary to be cautious and to be prudent, but then the application of this principle has to be guarded. If it be considered desirable to avoid fallacious hopes, and to discourage undue excitement and gambling, it is none the less desirable, on the other side, to be cautious and to be prudent, so as not to impede or discourage the legitimate development of any resource of our Indian empire; particularly this, for gold is greater than indigo, than tea, than cinchona. This is a right side of prudence, for if we take a false step, then in this case, as in so many others, we shall throw back for years the advancement of the population. It was such hesitation which postponed the commencement of the railway system in India, and which has deprived the country, even to this day, of its full benefits, and such examples can be multiplied.

It appears to the public, that the discovery of gold in India is indeed one of the most remarkable events in this age, which has seen so many events materially affecting the destinies of the human race. The re-discovery of gold in California, and its discovery in Australia, greatly as they acted on the enterprise of the world, yet as the operations in connection with them took place in countries thinly peopled, they did not have the direct influence which must result from the development of gold mining amidst populations numbered by hundreds of millions.

In the same way as the existence of gold in India is regarded as a new fact, so is the extent of the formations regarded by many with doubt. It

is beyond the power of any one to determine profitableness of the new workings, or the manner in which the condition of India will be modified, but the careful observer cannot fail to ascertain from history that the antecedent circumstances are such as to give importance to character of the present development. This what we have now to take into account, not as results, not possible loss, but the real gravity the explorations, so that we may neither exaggerate our expectations, nor neglect by carelessness what may be fairly esteemed to be of good value to the empire.

The gold of India is traditional,\* and yet, in days, gold had become scarce in those regions. There is reason to think that the poetical legends of a golden age are not without foundation, and that they refer to a time when the river sands the world and the alluvial formations were won for this metal, which furnished the hoards of kings of old.† This golden age was followed by the archæologists agree with the poets, by a bronze or brassy age, and then came the iron industry giving name to the iron age.

Wherever we look we find that the rivers have been cleared of the accessible gold, and we have evidence of very old workings. India affords the same testimony. In ancient times its counts must have been the richest, for, besides its whole area, it has numerous rivers, in most of which gold is still found, but of such poor yield as to be scarcely worth working, even where the rates of wages are so nominally low.

There is scarcely a river in India but gives evidence of the wide diffusion of gold, though the rise in wages has reduced the extent of the working from what it was 40 or 50 years ago. In the Indus, between Attock and Kalabagh, as much as 2,000 oz. yearly used formerly to be got. Gold is found in the basin of the Ganges, in the Gomti, the Ramgunga, and other rivers, particularly those running at the foot of the Himalayas. Hence many are now inclined to look with interest on possible discoveries in those regions. In Southern India, there can be little doubt of the known sites in the Wynad and Mysore; the only indications of larger formations. The washings are numerous in the Assam province and it has even been estimated that, at one time the yield was near 40,000 oz.

While the numerous ancient workings are admitted as acknowledged evidence of former yield, yet they constitute with many a solid element of doubt, because it is considered a cessation of working is an indication of pure worthlessness.

Ancient workings are found in many parts of the world, as in Spain largely, and in this country to a more limited extent. Thus, we are able to form some idea of the influences which may interfere with operations. The interruptions are not necessarily dependent on failure of ore, or mines which have been abandoned for centuries.

\* On the possible connection of South India with Ophir of the Bible, see an interesting letter, by Mr. F. H. Conder, in the *Archæologist*. Mr. Samuel Jennings has dealt with the same subject but the reference has escaped me.

† See my book, "Khita and Khita-Parevian." (Trilohar Co.).

‡ "Notes on the Distribution of Gold." James Wylie, *Chemical News*. Pp. 25 and 27.

resumed and kept in a state of production for long periods. Political and social events greatly affect these results. At former epochs mines were generally worked with convict or slave labour, and at other times with serf labour.

A war, or an invasion, as that of the Mohammedans, would stop slave labour, and likewise affect the continuance of the skilled labour necessary for supervision. The stoppage of mining of itself constitutes an obstacle to resumption; so in the case of arable lands, the abandonment of cultivation brings its own evils and impediments. Wood covers the open country, and wild beasts find shelter, while the water-courses are interrupted, and marshes are formed, with fever as an attendant consequence. In abandoned mines, the shafts, pits, and galleries fall in, timber rots, and water accumulates. By and by the knowledge of the productive parts is forgotten, and workmen having left the district, the local traditions are lost.

Mines were, besides, worked by what has been here termed serf labour. The resident population were compelled to contribute labour for the mines, and those beyond to cut and transport wood for timbering and fuel, or to find carts and beasts to convey supplies and produce to and fro. Such compulsory labour is compensated by nominal wages, by remission of taxation, or by exemption from military service. If, however, the population is interfered with by civil or foreign war, or is removed from the strong hand of despotism, then the whole system is relaxed, the technical training disappears, there is an indisposition for mining employment, and it becomes very difficult to retrace the former regulations and restrictions.

Thus in Asia Minor, for instance, the relatively silver and copper mines were kept working with alacrity, and many were abandoned. The Tokat or mines and the silver mines of the Gumushaneh were kept going by exceptional richness, although the Ottoman Government hesitated as to the economical value of the traditional system. It was gained in copper and silver was converted to be lost in taxes and service, and the same have consequently been sold.

The condition of mining is generally artificial. The public form their estimate from some places exceptionally rich product, but mining generally assumes the character of poor and uncertain returns, as precisely as the fisheries; many a mine in the world costs more than twenty shillings for its day's worth of produce. The operations are often looked on as a gamble by those who contribute to it, equally by those who contribute labour on or to it. Whaling and sealing encounter the same vicissitudes. Not even agriculture is so irregularly worked as such operations. Everything in the hope of mineral is tried and raised at a loss, but profit or with profit; a slight decline in the price will throw the poorest mines out of business, and a small rise causes them to be opened. It is differently from agriculture and from fishing, the product of mining is put in abeyance, and added even for many years, until a return of gold or greater prosperity. The farmer goes on working something in the famine years, but the miner stays his hand. He is always, to some degree migratory, and he can turn to other employ-

Thus, in a career of such vicissitudes, there are recurrent epochs, in which every shaft is fruitless, and the condition of the Indian gold mines is not exceptional. Their abandonment in no degree shows they cannot pay; it is no argument against their resumption, and none in favour. The value of the Indian mines must be determined by conditions altogether apart from such facts. The facts are in favour of the general existence of gold formations, and, considered in this light, they are of great importance, for they bear testimony to an extent of formations, illustrative of former enterprise, and inviting present consideration.

The condition of the old workings is very well described by a gentleman of authority, Mr. Samuel Jennings, F.L.S., F.R.G.S.\* He says, the native system consisted in the sinking of perpendicular shafts on the reefs and other workings around the base of the shaft, so long as it was safe, and working the alluvial deposits on the sides of the hills, so long as the dry weather continued; but as soon as the heavy rains of the season set in, work became impossible, and, as has happened recently, the rain has destroyed the excavations, by choking them up with the debris and earth that had been loosened, and the whole operation had to commence again anew. Thus, in process of time, the entire surface, to the depth of 20 to 30 feet, was completely turned over, and all the precious metal extracted. The same state is found in the West African workings. The idea, says Mr. Jennings, of protecting their shafts by timbering, does not appear to have occurred to the native miners, whose powers of penetration seem to have been limited to the extent they were able to excavate in a single season.

In my opinion, there must, however, have been more able mining by the older races. An adit, 126 feet in length, on the Kintail estate, seen by Mr. Brough Smyth, is a type of this class. There must have been in ancient India the identical workings of the old miners, of which we have such fine specimens of Roman and earlier times in Spain and Britain.

Although gold production, under an energetic despot, may have been carried on with good results, a small despot or chief would not be equally successful in the attempt; on the contrary, he would find every obstacle. He would have to obtain assistance from without, and train workmen for the extraction and the reduction. Thus, it is not at all surprising that the recent representation of the ancient wealth was found in the gold washing of the Kurumbar. We must hesitate to take minimum results of Kurumbar efforts as any measure of what is to be achieved under operations, by machinery, quite beyond the compass of simple gold washing.

In South and Central America, in many cases where regular mining had ceased, the Indians would, by a few days of river washing, get such a small quantity of gold as was required for their new purchases of goods from the traders. On this head some misconceptions prevail, for it is supposed that the gold washing is not kept up for some mysterious reason. The real reason of the casual production is, that the Indian is not by pursuit a gold washer, his food is obtained by other means, and the gold is sought as a special commodity, for

a special use. Gold washing, too, is not a favoured employment in most parts of the world, but one that is irksome, and is only carried out on a large or continuous scale by compulsion.

Nothing can be a better testimony of the neglect of a gold district than its falling into the hands of the native washers, who have only the simplest apparatus. The most inconsiderable application of better expedients, as of a cradle, alters the whole arrangements, and is attended with commercial results. The native gold washer can get through but little material, and, even when most expert, in some districts, sends into the current much of the gold.

Political events, as has been said, must have exercised the greatest influence on the alternations of gold raising in India. When we look back and consider the previous events, which have so affected the regions now attracting interest, we shall be able to allow or others far remote, or unknown to us. While gold, when accumulated, dazzles the imagination, we do not conceive the precarious course by which these accumulations have been brought together, and that, so far from its being in the nature of things that the collection of the metal should be constant and never be interrupted, it can only take place under very favourable circumstances.

In the early stages of discovery, it is very difficult to arrive even at an approximation to the yield. The assays can only be those of casual specimens, giving no real estimate of the result. An assay must depend on the sampling, and though this can be effected with a poorer ore like copper and lead, it is difficult with gold where a very rich metal is widely disseminated.

Even where assays are applied in a practicable way in gold mines, there is often a large difference between the assay and the practical yield, even when the tailings are assayed. Gold, from its nature, can be distributed in such minute fragments that it is not mechanically secured, but remains in the stuff, or is floated away. In a mine so productive as that of the St. John del Rey Company, in the Brazils, which has given dividends for above half a century, the best estimate is that the recovery of gold has only been from 70 to 73 per cent., leaving from 27 to 30 per cent. for possible loss, as the processes applied to the remaining material are successful only to a small extent. The only possible estimate to be formed is from the whole yield of a mine like the St. John del Rey, and then a large deduction must be made for possible loss of metal. For gold working there must be gold on the spot, but even then the commercial realisation is not secured. There is gold enough in the world, the existence of which is ascertained, but which is not extracted. This is the case in Central America, in Colombia, in Venezuela, in Peru, in Bolivia, in Brazil, in Africa, and, indeed, throughout the whole world. If the place has not facilities of access, if there is no good supply of suitable labour, and, above all, if there is not sufficient water, the mineral remains unworked.

If the mines must be worked and drained by powerful machinery, it may be impossible to place such on the spot, for want of roads suitable for conveyance. Even if machinery can be placed, it may be of no use for want of fuel, or for want of

water-power. Thus a variety of conditions to be regarded in forming any opinion of the value of any district.

On account of the small quantity of metal gold stuff, large quantities of material must be pounded in order to get it into a state for reduction. Thus, generally, water is an essential for all operations, unless the metal exists to such extent, that the ore can be conveyed to any place for reduction. Where such is not the condition, the mines remain unworked in some climates, and where there is known to be enough.

II. So far as Indian gold is concerned, the districts now under consideration are in a hill region subject to a very heavy rainfall. This is cut off by streams, and in some parts will not be available, and cannot be pounded or secured by bends. There are, however, estates where streams and in other districts storage, are available for water. In fact, India in these respects has advantages equal to most portions of the former regions, and beyond Australia. There are few parts of New Zealand better provided than are there in Brazil.

Thus, where an estate has a good reef on which the water well laid on, the prospects must be looked upon as hopeful. Still, there will be vicissitudes, a season of short rainfall, the bursting of dams, and various incidents, which will interrupt steady working.

Calculations are put forward that a large inordinate amount of capital is already invested in Indian mines, but it is quite idle to give figures. The greater part of the amount subscribed being for the purchase of estates and gold formations, constitutes a mere transfer of the country is neither richer nor poorer, but individual wealth may be affected, and the position of one person or another. The true application of capital is for the export of machinery and for the remittance of wages for workmen.

The truth is, so far from a large amount of capital being provided, it will be found in more than one case that the capital is insufficient. Whenever a large proportion has been applied for purchase of money, the working will be starved, and even a good mine may prove unremunerative. In cases, the first capital being exhausted, the original holders may have to submit to a total loss, the next comer may get a large return on a small investment. These are the contingencies of mining, and the large prizes draw people into operations. It is the last purchaser who obtains the whole return for all the capital which has been sunk in the concern.

The fact is, the absorption of capital will be to a great degree, self-regulating. Only a limited amount of capital can, in 1881, be applied to opening out, to working and to machinery. The same in 1882, and in 1883 very little capital can be applied, unless some return has been seen. It will be found that so-called gold lands cannot be sold for fabulous high prices, any more than nominal low prices.

A real loss of capital will be incurred by the enormous provision of machinery. Wherever too much a quantity of machinery has been sent out, for mining requirements, but to produce an effect on the Stock Exchange, and to run up the share

may be looked for. Whenever a mine is of working, although the machinery may be in fair order, it seldom fetches its value when the removal of machinery is very difficult. When machinery is kept too long, during a season, it likewise deteriorates, and may be sold to old iron.

As the real investment of capital in India, notwithstanding much loss, a fair return to this may be expected. Machinery makes a market for other machinery, and so does the supply of pioneering workmen to a country. With a number of such men attached to the mines, it becomes possible to introduce and use other machinery not otherwise available. The expenditure on wages is not likely to be excessive; it will itself, as, when found unremunerative, it will be stopped. Even the large salaries of superintendents and skilled officers cannot be a total loss, as many of these men will remain, and open new enterprises. A very good example of this is given in the *St. James's Gazette* of this year. In consequence of the increase of silver in the Linares lead district of Spain, the growers have taken to the purchase of steam machinery, instead of the old wooden adzes. It will be noted that the Belgian miners, having got into the district, have derived the benefit of this new business, although rather a speculative mode of regard; and other such operations, it is a true saying, whatever the direct result, there must be a benefit from introducing into India Englishmen and enterprise. Such considerations are of particular weight, when we come to the national relations of such undertakings. As we said, indeed, we are hedged against loss on every point of view. It is in this respect that the gland in the long run is found not to have been a disaster in the many disastrous ventures in silver of fifty years ago. The internal losses are so painful to many over-speculative persons, that the event, the country was no loser. As there was some loss in Brazilian mines, but it gave a return, and in the end we have added on the produce of Brazil, which has in the end of ways been a benefit to us.

It is from no single set of figures that the influence and value of such operations can be gauged, and they must be examined as a matter of fact in their full results, with all their losses and their gains. These the balance-sheet of a company will not disclose, as it will not show the effective distribution of capital. There is a loss to the shareholders, and gain to the miner and the merchant.

One important consideration is the supply of labour. The want or failure of this has put a stop to the mining industry in many countries. Thus, in the Portuguese times, the numerous and remote mines of the auriferous districts depended on the labour of the natives. With the emancipation of the whole districts were thrown out of yield, and only by close attention that labour has been secured for the St. John del Rey mines, and the demands have been kept up. The supply of labour must be free and continuous, and consist of men who are disposed to engage in such a product. This is the strength of Chile, where the natives are to undergo the drudgery, and receive

regular wages, or, as tributaries, run their chance of the prizes of rich and casual finds.

It is likewise necessary to have English or other foreign miners who understand the business, and are willing to go abroad, and encounter, with or without their families, the vicissitudes of distant travel. So far as this population is concerned, we have it at home in Cornwall and Wales, whence many proceed, not only to English countries in Australia, South Africa, Canada, and the United States, but to foreign lands. They are as familiar with the hot climates of Brazil, Chile, and Mexico, as with any of the regions they frequent. Then there are our Australians. There would, consequently, be no difficulty in obtaining a supply of workmen for our Indian empire, where they are under English protection. The same circumstance will favour, in case of need, the introduction of foreign miners. The mass of the labour, however, will be local.

Our own people are well acquainted with gold mining in Australia, New Zealand, California, Brazil, and Columbia, and it is not a business that they have to learn, but one in which they have been largely engaged. Much, too, depends on the enterprise of such men, for many classes of working can only be carried on by the participation of such men as sharers or tributaries, one of the forms of mining enterprise which distinguishes it from most branches of industry. It is, too, an inducement which brings in labour and intelligence, as well as capital; and mining depends, not solely on the capitalist, but, in many cases, largely on the co-operation of the working men, who share the risks as well as the profits. Thus, the risk of the capitalist is sometimes reduced; but, at all events, something more than the efforts of the capitalist is brought to bear, and so it will be in India, where the individual labour will be stimulated by an incentive beyond the wages of labour.

III. Apart from any operation on the coinage of India, and on the exchanges, it is to be expected that a much more important influence will be effected on local prices of wages and commodities. Looking at these from an English point of view, it has been too much the custom to consider them as dependent on English conditions. There is, however, very little contact between what may be called the English system of prices, and the Indian system of prices.

The contact is effected by the export from India to England of sugar, coffee, rice, cotton, jute &c., the prices of which for export are determined by the London or European market prices. This, however, exercises very little influence on the main bulk of the agricultural crops of India.

Far different are the relations between England and the countries on the adjoining seas, Ireland to the west, and the shores to the east and south. Every pound of meat, every fowl, every egg, each pound of butter, and all fresh vegetables or fresh fruits, are liable to be taken up for the great markets of London and Paris, the prices of which, with the cost of transport, govern those of the outlying districts. Hence, the general complaints of the growing dearness of living in the large and small towns, and which tends not to a levelling of prices in the proper sense, but to an augmentation of prices to the higher standard.

Within each region, the completeness of railway

transit contributes to such results, and the seas are bridged by steam transport, also penetrating the rivers. The prices of food affect the prices of labour to a considerable extent, and modify the operation of other causes. The Irish labourer, who, half a century ago, received 4d. to 6d. per day, or Indian wages, now receives 2s. or more.

In India, as has been pointed out by me, in common with others, similar results have, of late years, been seen in operation, but they have not reached their full development, and must, therefore, continue until it has been attained. This is the point to which the attention of economists must be turned, because the quicker or slower rate of this development means the earlier or later attainment of an advanced condition by the population of India, and the consequent rate of public revenue.

So long as the great disparity of rate of prices between India and England exists, there must be a disturbance of all economical relations. There must be a really abnormal relation of imports and exports, an abnormal disproportion between the amount remitted to England and the rest of the revenue of India, a false relation between the supply of capital to India and its returns.

Taking this last head alone, India labours under great disadvantages as compared with many other countries. If a railway be made, say in the United States, with English capital, then the returns can be calculated upon at something like English prices. In India this is not so; the railway iron and machinery shipped from England is of the same identical cost, but the carriage of commodities and of passengers has to be undertaken on a scale wholly different. No question arises elsewhere, for instance, as to the carriage of passengers at 2 pice per mile. In some countries it is possible to charge an anna or two, as here at home.

That, in many classes of enterprise, where the amount of traffic, or transport, or commodities dealt with in India would, at what may be called normal rates, produce a good return, in India they give an insufficient money yield, the undertaking becomes impossible with profit, or without a guarantee burdensome to the Government, and the abundant capital of the European markets is not applied to India, while it is freely available for alien countries, which have no claim on English sympathies, in Brazil or in Chile.

It is the rise of prices now going on in India, and already referred to, which will act independently and concurrently to affect the situation, and dominate the commercial and financial conditions. It is, therefore, perfectly futile to talk of the application of great economical laws, when we neglect the circumstances on which their operation depends.

The development of gold working means the development of English knowledge and enterprise, and the consequent progress of India. Then the railway system will no longer be stinted, and the correspondent benefits will be obtained. Many a commodity will rate locally at a higher price in consequence of higher wages, but the efficiency of railway transport, as compared with the bullock cart, will place the commodity at the port, under commercial conditions. Many commodities, which now cannot be moved and are excluded from trade, will, under quick transport, become ex-

changeable articles of commerce. If these results were only to be regarded as possible or probable the whole subject of the gold fields would be worth of the gravest consideration, and as one not to be dismissed on doubts, or on the absence as yet ascertained realisation.

Nothing, indeed, is more familiar to the old Indian statesman and resident than the alteration and rise of wages and prices which have come home to him in his own time, a rise which has been continuous and the conditions of which we know will never be reversed. Even in the Wynaad this has been striking as anywhere else. In 1833, rice was 20 to 30 seers to the rupee, and a sheep, even Ootacamund, 12 to 16 annas. In 1833, the wages of labour were 2 annas 6 pice per day, but the earnings of a Kurumbar gold washer were estimated at 2 annas per working day.

In 1876, the Prince of Wales's Company was from 4 to 5 annas a day, and it may be that in Australia the wages are more than annas, being from 6s. to 8s. per day.

This rise of prices, which strikes every one recorded by Sir Richard Temple as a general affecting India, and is, in this respect, brought forward as a topic in his "India in 1880."

The time must come with the working of gold regions of India, that the wages will be practically the same in Wynaad as in Victoria, and will not impede the gold workings, because, in Victoria, the poorest stuff is raised to a profit at high wages and high-priced food.

IV. It is difficult, in any reasonable compass, to give a fair idea of the extent of the gold regions of India, or to effect this by either historical or topographical treatment. If at the present moment the Wynaad regions concentrate attention on them, they cannot be regarded in any general consideration as entitled to sole notice. Old districts in ancient times were better known, and there are mineral formations in outlying regions which, on examination, may prove to be productive and which may give unexpected value to countries now regarded as undeserving of attention.

On this occasion, we must direct our notice to Wynaad and the neighbouring lands. These may certainly be considered as an old and recognised gold district, at whatever opinion we may have arrived as to its practical utility. The old world attests its former and continuous occupation in mining, while the petty operations of the new gold seekers preserve the tradition, rather to prove, the extent or importance of the formation. More than once, in later times, attention has been directed to the possibility of turning these indications to account, and that chiefly in dependence on the historical indications. The earliest historical evidence, however, that we as yet possess, is that brought forward by the eminent authority on the archaeology of India, Dr. Burnell, quoted by Mr. Eastwick and Mr. Brough Smyth. In his notes on the Great Temple of Shiva, at Tanjore, he is of opinion that it could only be by gold treasure that the Rajahs of Southern India could raise in the eleventh century the great temples to Shiva and in the twelfth and thirteenth centuries those to Vishnu. Were there nothing else to support this conjecture would fall to the ground, because the temples were not really constructed with gold but with labour, like the pyramids of Egypt, and

labour or food had been imported from without, and paid for with gold. Any gold expended within the country would, under most circumstances, remain within it, and be again collected into the treasury. Dr. Burnell, however, brings direct proof as to the abundance of gold, by his successful decipherment of a remarkable inscription in the Tanjore Temple. Dr. Burnell is thus enabled to state that in the eleventh century gold was still the most common precious metal in India, and stupendous quantities of it are mentioned. He, too, considers that this gold was obtained from mines, and that the Moslem invasions interrupted their workings. This is the opinion which appears best to account for the facts known to us.

Mr. Edward B. Eastwick, with his accustomed power of research in Oriental history\* has treated of the historical data. He records that, in 1523, Allāhu'd-din took the City of Deogarh, and smashed the citadel, receiving besides 175 lbs. of pearls, 50 lbs. of diamonds, and 25,000 lbs. of silver, as much as 15,000 lbs. of gold. Although this is supposed to be an exaggeration, there is no reason to deal with it as other than the actual conditions of the treaty made and recorded, though the value of the gold would be some £600,000 sterling. Such a treasure is by no means unexampled in history. Indeed, the accumulation of treasure was as great a political end as was the increase of territory, and each conqueror possessed himself of the accumulated stores of his victims.

Tippoo Sultan possessed great quantities of gold. In Maxwell's "Life of Wellington," it is stated that he was to pay to Lord Cornwallis, under treaty, three crores and thirty lakhs of rupees in gold mohurs, pagodas, and bullion, equal to about £3,300,000.† On one occasion, Tippoo sent thirty-eight camel loads of money to Scindiah, to buy him over as an ally. By the estimate of treasure and property taken at Seringapatam in 1799, it is clear that Tippoo had been able to make fresh accumulations of specie; there were 16,740,350 star pagodas. His throne had, at least, £30,000 worth of gold in it. Besides this, he had paid large sums abroad for war supplies and political purposes.

Whether this gold was obtained from the mines of Southern India is uncertain, though the Commissioners, in 1833, state, "it is pretty certain that Tippoo attempted to make them a source of revenue during his possession of the country" which was included in his dominions. Indeed, all the English inquiries turned on this point of the known existence of the metal. In 1792 and 1793, a joint Commission, from Bengal and Bombay, was appointed to examine the state and condition of the province of Malabar. The Commissioners refer, briefly, to the occurrence of gold, in treating of the subject of the royalties claimed by the Nijahs, which is stated to be on "all gold ore," and also of "compositions of gold," which were found in the Nilambur district.

In 1793, Mr. Duncan, Governor of Bombay, formed a strong opinion of the value of the mines, and took some steps to ascertain the extent of them. In 1802-3, the auriferous rocks of the Nilambur valley are again mentioned, and, in 1813, a work

was published by Dr. Whitelaw Ainslie, in which an account was given of the localities where gold is found in India. He says, "Gold dust has been found in the bed of the Godāveri, and in Malabar in the bed of the river, which passes Nilambur in Irnaad district. It has, moreover, been procured in very small quantities in Wynaud, in the Aroot district, and in the sand of Beypore river, near Calicut. Though the sources are evidently numerous from which this valuable metal can be obtained in the Indian peninsula, it would seem, from the little interest they have hitherto excited, that none of them promised to be very productive."

It must not be argued that the Indian authorities were so very remiss, for, apart from political disturbances, which attracted the attention of the authorities, there was no school of gold-mining in England. Such existed in Germany only, and the subject could, in England, be studied from books alone in a most imperfect manner. It was only at a later time that Englishmen were employed in gold mining and reduction in America and became conversant with it. It was not, however, until the Australian discoveries that we obtained a large and organised school within our own empire, which now justly holds a high rank. Indeed, the Spanish, German, and Russian schools are now connected with smaller operations, while the English and American schools are supported by practical works on a much larger scale. It is also by these schools that the application of machinery has been carried out, beyond the examples of the other and older branches of professional mining.

While this state of affairs accounts, to a great degree, for the assumed neglect of the Indian formations, it also accounts for the failures in the next epoch, when the Indian authorities more seriously and more earnestly turned their attention to their gold resources. Before the year 1831, Mr. William Sheffield, the principal Collector in Malabar, had been buying gold for the Government, and on the 10th January, 1831, he sent in a report on the several localities where gold was known to be found, and on the methods of mining employed by the natives.\* Mr. Sheffield made such an impression that Lieut. W. Nicholson, 49th Regt., N.I., was appointed by the Government to search for gold "in the mountains on the Malabar coast," and with him was associated Mr. Henry Louis Huguenin, a Swiss, as to whose qualifications we have no information. It may be mentioned that Lieutenant Balfour, R.A. (now Gen. Sir G. Balfour), being at Cobarr in 1835, noticed that his servants washed gold there. Every resident told him of gold. Such facts were of constant observation.

It will serve to show what erroneous and exaggerated ideas prevailed, that Mr. Huguenin stipulated with the Government that he was to have one half of the gold he might assist in finding and reducing during a period of twelve months, and the same proportion of all gold he might collect from the mountain streams, &c., by washing; the government having the right to take such share of the produce at the market price of gold.

Had the Government, or its conductors, had the advantage of experience elsewhere, they would have known such conditions were impracticable.

\* All this is derived from the sources previously quoted.

\* See "A Hand-book for India," John Murray. Article in *Scottishman's Magazine*. Letter to the *Times*, 2nd Jan., 1879. Notice from the same in "The Report on the Gold Mines of Mysore." By R. Brough Smith, London, 1860.  
† See authorities already quoted.

All the greed of the Governments of Spain and Portugal had resulted in their accepting a small tax or royalty in Mexico, Peru, or Brazil, although they might retain their monopoly of mintage or purchase. The Madras conditions could only result in disappointment.

Lieutenant Nicholson's mission was one of those in which our Indian officials have equally shown strength and weakness. With no practical knowledge, and with second-hand information as to European processes, but applying intelligence to the improvement of rude native processes, they have often succeeded in establishing large and successful works. Such was the success of the late Joseph Hume, in setting up gunpowder works. So, too, the late Mr. Heath succeeded in making the finest steel, and though he did not achieve a commercial success in India, yet this able civil servant was enabled to discover valuable processes, and in his day to revolutionise the steel trade at home. Some of the first irrigation works, too, are noble monuments.

The zeal and exertion of Lieutenant Nicholson deserved a like success, but, as has been shown, circumstances were against him. He carried on a course of explorations in 1831 and 1832, and we are now able to recognise that he showed great ability, and that he achieved a certain success. His dispatches will be found in the report of Mr. Brough Smyth, already referred to. Mr. Smyth, with an appreciative feeling, has produced Nicholson's map, which shows that Devala and many other gold sites were recognised. The party of Lieut. Nicholson suffered much from fever, while his prospects of success were lessened by the want of a sufficient number of assistants, by bad tools, and by an irregular supply of necessaries for his men. In fact, he was in the situation of some of the early parties in Australia and New Zealand, which, from like causes, failed in what afterwards proved to be fertile ground for others. He had, however, peculiar difficulties, for the petty rajahs caused obstruction, they misled his people, filled up shafts, and felled trees to stop the paths. As treasure was not found at once, nor seemed likely soon to be found, there was great discouragement, and on the 25th of May, 1833, the Right Hon. the Governor in Council dispensed with the services of Lieut. Nicholson, and appears to have abandoned all hope. They did not attempt to remedy the manifest defects of the expedition, they did not follow up its indications, but determined that success was impossible, and the belief was arrived at that gold did not exist for any effectual purpose. The Kurumbars, however, went on with their small scratchings, as they may be called, and did this further good, that they kept alive the memory of the gold formations.

In truth, the labours of Mr. Sheffield and Lieutenant Nicholson were worthy of a better fate. The attention of Mr. Sheffield was naturally chiefly directed to the river washings, of which he knew many sites. He also referred to Wynaad. He, however, repeated that "There appeared no reason to doubt that golden ore is homogeneous to the soil in the mountains and hills of Malabar." He proceeds to name Devala.

Lieutenant Nicholson came across many curious facts. In one place he found no less than 27 old shafts. In another he observed 500 or 600

Moplahs working regularly, and paying roy to the local zemindar or rajah, to the extent some £700 a year. He sent up some stuff the Devala mines, which gave metal in the portion of about 90 per cent. of gold, and cent. of silver, and a portion of copper.

Silver, so often associated with gold ore, appears to be a large constituent of those ore it will give occasion for the operations of mining, which can be affected in the present times.

One strange business of Lieutenant Nicholson appeared to have been the purchase of gold, view to an operation on account of the Government in which Mr. Sheffield had also been engaged.

It is to the credit of this officer that he saw his own deficiencies, and proposed to go to England to purchase machinery. He also offered a plan for forming a mining department and school in Madras by means of the Company's establishment at Chatham. These recommendations from a man had little weight with the Government, may be regarded as even less informed than his. In the case of the gold regions, as in other parts of India, it will be found that English intelligence and enterprise are the real and efficient engines for the improvement of our empire, and may be applied in a fuller measure than the staff of the Government can supply.

It will be observed that the fever incident to the district was regarded, half a century ago, as now, as a serious impediment, and this was a discouragement for gold working. It so happened that the availability of the district for gold mining was seriously undertaken, Wynaad and the neighbouring countries were occupied, and turned to account, notwithstanding all obstacles. The planters gradually became aware of the situation, and turned their attention to it.

In October, 1857,\* the acting collector of the district drew attention to the arrears of taxes payable by the rajahs for the right to mine, and so for the information as to the gold workings is derived from his reports. He could not define the localities in which the gold was quarried, but stated that the gold was obtained in very many small tracts interspersed throughout a tract of country extending for 30 or 40 miles along the western face of the Ghauts, and in parts along their summits. He stated that circumstances had altered so much that the business had greatly gone down in the last ten years, so that many of those who undertook the art had betaken themselves to other pursuits, and had carried away with them the knowledge of the localities richest in ore. As it was, however, the work, as it had been in Lieut. Nicholson's time, was carried on by slaves; a significant testimony to the poor returns. By 1858, whole families had been diverted to the employment of the coffee plantations. It was about this period that, for a time, I was honorary agent to the Association of Planters in Western India, and the gold resources of the region particularly attracted my attention.

It was not until 1868 that the matter of gold working was seriously treated, and then by the British who had settled in Wynaad. In that year, Mr. H. S. Sterne, who had six

\* See authorities recorded.

ience as a gold digger, applied to the Government for leave to prospect for gold and other minerals on Government land in the Madras Presidency. Permission being granted, he prospected in various places, but with what success is not known.\* At about the same time, Mr. G. E. Devals began to prospect, and became convinced of the fact that the reefs were auriferous, and of the value of the reefs. Owing to his labour and enterprise of Mr. T. W. Minchin, of Hamsalade, Devals, machinery was erected for reducing quartz found in the veins of the Skull Reef, and within the area of the company, which was called the Wynaad Prospecting Company.

From this period, applications have been continued until now for permission from the Government to work gold on private estates or on public land. These operations attracted much attention, culminated in what appeared to be, in 1876, a great industry of gold working, but the trials proved unsatisfactory, and, from one cause or other, great discouragement prevailed.

The chief of the original Wynaad companies were, the Prospecting Company, the Alpha Mining Company and its dependency, the Prince of Wales Reef Gold Prospecting Company. These companies were chiefly under local auspices. By the time the Government of India had obtained the services of Mr. R. Brough Smyth, then in the employ of the Government of Victoria. As to the operations, much information is contained in Appendix A, dated 18th February, 1879, to the report of Mr. Brough Smyth, p. 63. This report from Mr. Smyth to the Acting Secretary to Government in the Revenue Department, in consequence of instructions, under date January, to ascertain how it was that, with good ground, the Alpha Company had not succeeded. The mining operations of this company in February, 1875, and ceased in March, during which about 780 tons were raised from the main Skull Reef. From this only 91 lbs. of gold were obtained, or at the rate of .8 grains per ton. Of this, however,  $\frac{1}{2}$  tons of the Wynaad Prospecting Company's yielded 19 dwts. 22 grs. per ton, or nearly twice as much. The operations were, therefore, on a small scale, and afford very small materials for arriving at a judgment.

On the 1st June, 1877, the Prince of Wales's company took possession of the Alpha Works agreement, but did not begin work until the August, 1877, continuing to mine until the February 7th, 1878. The value of the gold was rather more than 8,000 rupees from about 15, and even that is not a mercantile result. The average yield was nearly 10 dwts. 12 grains. It appears the machinery was inadequate, but a cause of failure was the roasting of the ore in kilns, before sending it to the mill. The report was that the fusible lower sulphides of the gold, and prevented its amalgamation, comparing the average yields with those published by Victorian statistics, Mr. Smyth found that the reefs in Victoria favoured large results and dividends. He came to the conclusion that inadequate arrangements for the Alpha property would not give very good returns.

Among the vicissitudes of this history, is to be recorded that parties involved in the disaster of the great Glasgow Bank, were concerned in these mining operations. It fortunately happened that some far-seeing men, among whom may be mentioned Mr. R. Palmer Harding and Mr. Samuel Jennings, determined to turn the gold properties to account. Thus a new element of enterprise favoured the contest.

At the same time, the sagacity of the leading director in the Moyar Coffee Company, Mr. W. J. Rhodes, gave further strength to the new movement. Mr. Rhodes, with his colleagues, acquired the mining rights for the Coffee Company, and thereby obtained for it advantages of an exceptional character, though these services have not yet been adequately compensated.

The conviction impressed on a number of able men of the real character of the district, resulted, naturally, in the determination to prove its resources. The missions of Mr. R. Brough Smyth to South India, for which he was retained by the Moyar Company, undoubtedly greatly co-operated to strengthen these efforts, and to consolidate public opinion. Bringing to bear an acquaintance with Australian operations, his enthusiasm did not exceed his caution, and if any have been excited by his descriptions, they must have neglected the reservations he expressly made. Going into a country which, to the regard of others as well as of himself, presented the aspect of a great gold region, he had to give some general appreciation, by which its character could be understood. For this purpose he laid down broad lines, but with the express reservation that these were not determinate, and were subject to correction.

In despite of himself, many believe that the reefs, roughly sketched, are as exact as the determinations of the Indian geological survey, and that deductions may absolutely be drawn from such data. Other observers have applied themselves to the task of working out, in detail, some particular reef, and have given to it a more precise bearing, differing from that proposed by Mr. Smyth. At page 18 of his report, this gentleman says:—

"It has been considered advisable to use great caution in suggesting the probable connexion of the outcrops of quartz, as they appear on the surface—in laying down hypothetical data—so as to connect one outcrop with another. The direction of the lines of reefs may, from the surface indications, be guessed at; it can be ascertained in no other manner than by extensive explorations; and the facts mentioned in other parts of this report justify hesitation in laying down, as absolutely beyond question, any line of reef in the Wynaad."

He enforces this from the experience of Australia.

Nothing can be clearer than Mr. Smyth's warning (p. 19)—

"It is not unlikely, however, that the first attempts will fail. Speculative undertakings having for their object the making of money by buying and selling shares, are commenced invariably by appointing secretaries and managers at high salaries, and the printing of a prospectus. This is followed by the erection of costly and not seldom wholly unsuitable machinery; no attempts are made to open the mine; and then, after futile endeavours to obtain gold, and a waste of capital, it is pronounced and believed that gold mining on a large scale will never prove remunerative. It is pro-

bable that this will be repeated over and over here, as in other gold mining countries, until some one of the mines is opened by experienced persons, who desire to secure profits, not by dealing in shares, but by mining."

In the last year, 1880, and in this, numerous companies have been formed on a large scale, and great speculation in the shares has taken place on the Stock Exchange. While we may look for fair results from fair mining, and, it is to be hoped, for large dividends, after a difficult time, we must also look out for a large amount of individual loss, to be measured only by the greediness of the speculating persons. Some of these losses will be most severe, as, step by step, the gamblers are drawn in, stimulated by the real or supposed gains of others. Those buying at the top of an exaggerated premium will sustain all the distances of fall from that height to the lowest collapse, when the concern is sold off as worthless. Then the premium will be lost and also the subscribed capital. It will, however, be seen that the community will not suffer in the same degree as the individual, for the man who sold at the premium will have his premium. So, too, the subscribed capital will not be lost to the community, as what is paid to several of the companies for the purchase of the properties is a mere exchange. Much of the operation is, indeed, a gambling with counters, and none the less to be reprobated.

V. Some very good descriptions of the Wynaad and the Mysore districts have been published in the memoirs accompanying the Geological Survey of India, particularly the report and map of Mr. King, in May, 1875. Mr. Brough Smyth, in his reports, has entered into valuable local details. Mr. Oliver Pegler has given a general mineralogical sketch of much interest, which he has confirmed by subsequent explorations.

A map of the gold regions, by Mr. James Wyld, the Geographer to the Queen, is the best record we have as yet of the general conditions and the various discoveries.

Mr. Oliver Pegler says\* that the range of mountains of the Wynaad is of ancient formation, belonging to the paleozoic period, more especially to that of the Silurian formation, a matter of much interest. The highest peaks, as in the neighbourhood of Ootacamund, are formed of hard, dense, and crystalline rocks of the metamorphic series of granites, syenites, &c. The more fissile varieties are also here present, and, being softer, have yielded to the disintegration and denudations of time, and have formed the valleys and dells adjacent to the peaks.

These softer rocks are of a much higher colour than the harder granite and crystalline formations, and give a red and brown appearance to many portions of the surface of the country. The average height ranges from 7,400 to 8,400 ft., and the whole of the formations are impregnated with black magnetic oxide of iron, which, after a shower of rain, appears as black sand on surfaces where the water has run over in streams. This is particularly noticeable along the road sides. The crystalline rocks continue for a considerable distance down the slopes towards the Wynaad country, becoming lighter in colour, coarser in texture,

but more laminated and fissile in structure, changing into the gneissic and more laminated varieties of metamorphic rocks.

The extent of the available working ground in the Wynaad is, says Mr. Pegler, very great, and Mr. Brough Smyth, within a small area of 23 miles by 12, or some 250 square miles, determined no less than 90 outcrops of ore reefs. Some of these surface specimens were very rich, at the rate of £750 worth of gold to the ton.\* The Monarch Reef, near Devala, has been traced far above nine miles. The Mysore district is equally well spoken of. There is no doubt, indeed, of a truly auriferous region, and one of good character, extending over a wide area.

The whole surface of the ground, writes Mr. Pegler, is contorted, upheaved, and thrown about, forming upright ridges, valleys, peaks, rounded hills, and depressed surfaces. It is most difficult to determine the true strike of the strata generally. The whole country is ramified with a run of gold quartz veins, which are true reefs. The general run of these reefs is parallel, the direction of strike, according to Mr. Pegler, being almost generally, in the Wynaad, north and south, a few degrees west of north, and east of south. The dip of the reefs is very low, as seen at surface, and most generally to the east, varying, when cropping out on the brow of the hills, especially when heavily developed, from almost horizontality to from 20° to 39°, and increasing in dip in lower grounds. These reefs, which are met with in every part of the country, are often of great breadth, up to 15 ft., 20 ft., and 30 ft. of thickness, are composed of white crystalline, compact quartz, identical in every respect with the red quartz of Russia, Australia, California, Nevada, or any other known gold-bearing country.

Such being the resources to be worked, there come questions as to the local means for working. Water, the great necessity for gold crushing, when fuel is not readily available, is supplied by a heavy rainfall. Mr. Brough Smyth states that the rainfall at Devala, during the years 1869 to 1876, varied from 109 inches to 117 inches, and at Vellerymulla, during four years, from 100 inches to 139. As much as one inch of rain sometimes falls in an hour, and nine inches in a day, the destructive effects of which in some places may be conceived.

Where water is scarce and fuel dear, a relatively rich spot may be less valuable than an estate with a poorer gold reef.

The next natural commodity is timber for mine timbering, and tools, and for fuel, and this, within certain limits, can be freely obtained. It will tax the forest administration† to keep up this supply, and to prevent waste.‡

Labour, apart from technical labour of imported miners, is available on the spot. The Moplahs and Kurumbars have also been accustomed to gold working. The coffee plantations have trained up labourers. It will, however, prove fallacious to form estimates on the present rate of wages.

So far as Europeans are concerned, climate is to

\* *Mining Journal*, January 17th, 1880, p. 67. In the *Mining Journal* will be found preserved, as customary, the current information on the subject.

‡ A list of woods supplied by, will be found in Mr. Brough Smyth's Report, pp. 58, 59.

considered. With a heavy rainfall, and luxuriant vegetation, malarious localities are prepared, there are seasons and places to which Englishmen should not be exposed. Miners, however, work under ground, and in mines at home very high temperature. There are, however, where the coffee planters are able to reside in estates with their families during the whole year.

Then there is the station of Ootacamund, a place for health and pleasure within the neighbourhood, which will afford a great resource. A large district, with a floating population, is not, however, to be regarded as a colony, like New Zealand, in which men are to spend their lifetime.

Accessibility may be regarded in connection with other conditions. Within four miles of some of the Mysore mines, is a railway station in union with the main Indian system. Although the railway to Ootacamund has not yet been completed, the plan is delayed for want of capital, and gold operations will stimulate its completion. From such particulars as to these, as have been kindly afforded to me by Mr. J. Danvers, the head of the railway department, and Col. J. F. Smith, the chairman of the Mysore Railway, there appears to be no reason for hesitation as to some provision for passenger traffic being ultimately made. So far as Wynad is concerned, there is the great advantage of access by sea and other ports on the western coast, within 30 or 40 miles of some of the gold-bearing mountains, the elevation to be reached is, as already stated, great, and to be ascended over a country very steep. Thus, with a seaboard nearer than New South Wales, Victoria, Queensland, or even Armenia, and more accessible than San Francisco, reaching heavier than a few hundred weights can now be taken up to a mine without difficulty and uncertainty. All the weight has to go up, supplies for the mines—except such food as can be locally obtained—but the weight to go down is in pounds of gold, easily to be carried—a return freight quite out of proportion.

On the seaboard, machinery can readily be placed,

but it must be so devised as to be suitable for mountain regions. Upon the general nature of gold machinery in Australia, the recent paper of Mr. Alfred S. Lock, read before the Society of Arts 19th January (*Journal*, p. 131), and the adjourned discussion in *Journal of the Society*, p. 160, may be usefully referred to. As chairman, I made some remarks from my own experience and observation, not without connection with the present paper.\*

With regard to gold lands and regulations, the Government have dealt with the matter judiciously. They have not been led astray by false notions of administration, and of large gains to be directly enforced, but have turned their attention to the practical experience of Australia.†

The late Governor of Madras, the Duke of Buckingham, showed a liberal appreciation of their importance, by visiting the gold regions on the 1st November, 1878, when gold was found in his presence.

VI. If gold should be produced extensively, it will settle the question of currency and exchanges, for not only will gold be at hand for coinage, but silver, thereby diminishing the import of silver. The Wynaad gold has a large proportion of silver, say 15 per cent. in weight.

Mr. Daniell‡ and the *Economist* have pointed out how large a proportion of the import of specie into India consists of gold. Although during the latter years the import of silver rose so high as to be from £16,000,000 to £20,000,000 per annum, yet the gold import also ranged high, reaching in one year nearly £10,000,000. In the latter period we have the extraordinary silver import of nearly £16,000,000 in 1877-8, yet the gold import was kept up steadily. Upon this Mr. Daniell rightly dwelt, and it is of such material import to the consideration of a gold currency for India, that it will be very useful to reproduce the tables in the *Economist* of 27th November, 1880.

\* Mr. Lock also proposed a Gold Institute, which is well deserving of realisation.

† See report in R. Brough Smyth's report.

As these two questions of currency and exchange are closely connected, so, in the joint considerations, they have been mixed up, and the difficulty of arriving at a consideration has thereby been aggravated. I am not unaware that the opinion of many of my friends among the economists is opposed to a gold currency in India, but, with every respect for theoretical considerations, it will

be gratifying to see the solution of facts. The currency settled, the exchanges will settle themselves in a manner satisfactory to economists.

As there are two schools of thought in political economy, and although the historical school of the old English economists is rather out of favour there will be no harm in regarding India historically. History shows us that it had an abundance of gold and a gold currency, so that, although prices were small, the small gold fanam was favourite coin, just as we find similar minute coins in the regions to the westward. It is, however, believed by many to be impossible to work a gold currency in India. A gold currency, nevertheless, will work with a low rate of prices, and we are not obliged to regard a gold currency as a matter solely of sovereigns and mohurs.

In those ages, when India raised gold and trade with the Arab regions to the eastward, there could have been no great difficulties, for in those regions the range of prices was also low. The Mussulman conquests disturbed the sources of gold supply in India, and reduced the stock, and at length we come to the state of affairs which we have in the day, wherein India has not merely to contend with the metallic question, but it is brought in contact with the enhanced prices of the west, and with the machinery of production which destroys her manufactures. A like conflict is going on in Japan. In both countries a partial remedy is being obtained by the rise in wages and commodities. The contest is, however, with a growing antagonism because the process of mechanical invention in the west creates an ever craving demand for these most and most expensive appliances of civilization. Railways, iron and steel ships, and arms of precision, typical necessities of the new social system are only to be acquired at a real sacrifice by undeveloped nationalities.

While Australia can make its payments with

col, and Peru with guano, India has to provide many parts for a most dense population from the produce of the soil. Commodities for exchange and port are only to be obtained by displacing articles of food. Undoubtedly, the local circumstances of India are peculiar, and create difficulties in the way of adjustment, but these can be met by due provisions. In this, as in other cases, India must be administered and legislated for, not directly on external considerations, but in reference to its own circumstances, still always with the direct end of bringing India to the standard of the empire and of Europe.

It is the fact that, historically, India had a gold coinage, and there can be no local objections to its having a gold coinage now, as well as a silver coinage; indeed, any objections to this must come from the outside. In the world we find a gold coinage predominant, and those who object to a gold coinage for India are those who object to metallism as a system, and maintain a gold currency here, and are, consequently, to some degree, inconsistent. Undoubtedly, any change in India must be attended with disturbance, and this raised is an objection to change. The disturbance, however, is already most continuous and severe in relation to the rupee currency, and the objections to future disturbance become small in degree, when we have to regard the prospects of improvement to be realised. As to change in India, there is no alarm to be entertained as to change by itself, provided that change is judicious. India, like the whole earth, is under the dominion of change. That great engine of society, the railway, which affects the transit of men and the transport of commodities, has done, and is doing its work of change in India and elsewhere, and the people accommodate themselves to it, and will never abandon it, but for some other improvement.

There are those, and these are many, who long since have advocated a gold coinage and a gold standard for India, in communion with the rest of the empire, and I have been among them. So strongly has this necessity been felt, that measures for its realisation were at one time far advanced. Had they been years ago put into operation, by this time the consequences of disturbance would have passed away, and India have been brought to its true position in connection with the rest of the world.

This has not come; the question has been taken out of the domain of practical politics and left in that of theoretical economy. With all due respect to economists, administration is not to be under the rule of theoretical, mis-called political economy. The distinction has, unfortunately, not been sufficiently regarded, though in India there have been many statesmen whose political instincts have induced them, on more than one occasion, to adopt the rules of real reason in preference to those of scholastic doctrines. Political economy has suffered a reaction consequent on its abuse, and is weakened by absorption by the so-called social science, which is only a meagre substitute for political science. By attempting to apply political economy beyond its bounds, it has been exposed in more than one country to the supremacy of the utilitarian school. Nothing is of more moment to India than the rightful administration of political

knowledge as an applied science. If its peculiarities are to be regarded, then its relation to the rest of the world is also to be regarded, for India is at this day bound to our empire by political ties, and to the world at large by commerce, and cannot be left in isolation. Many of its supposed peculiarities are common to other countries. Were India independent, as Chile or Peru, it would be drained, as it is now. Chile, for instance, has to pay as much to us in proportion for warlike supplies, for interest on railways and loans, for our share in mines and in commerce, and for the maintenance of the English colony there, as India does.

Most of the alleged grievances have no real connection with the necessity of English rule in India. This relation will have no more real effect when the condition of India is altered by the gold supplies. The gold supplies will be coined, and much of this coinage be exported, as is that of Australia. There is no reason, then, why this coinage should not be like that of Australia in sovereigns, although smaller coins may be struck for local use. Coins are not always used for circulation, some are hoarded, some used as ornaments, some re-melted by the goldsmith. In England even, many a sovereign goes into the chain maker's melting pot.

The balance of facts is in favour of a sovereign coinage for India, and then the silver rupee coinage would become token money. If India exports gold sovereigns, the exchanges will be under modified conditions, both as regards the imperial operations and those with abroad.

In my range of experience, there is one quality of the sovereign standard which particularly recommends it for India. The pound sterling is something more than an English denomination. As it is exempt from the tampering which has affected the currencies of so many countries, it is accepted in all the money markets of Europe as the chief denominator for what are called international currency or bonds. The London money market is also regarded as safe from the revolutionary attempts which have from time to time created alarm in continental countries. Bonds with coupons, solely or alternatively payable in the pound sterling, are preferentially dealt in in all the great money markets. They have an ultimate determinable value, giving them the character of a resource and a reserve under all circumstances, and they have a special property for purposes of remittance, either as bonds or coupons, for the settlement of transactions, constituting an effective international currency.

One great want of India is capital, for whether technical financiers for a time impede its application by an artificial entanglement with the public revenue, events will enforce the emancipation of capital from these trammels. At present, the supply of India, as compared with our colonies, or foreign countries, for public works, provincial or city loans, is most contemptible. When the demand comes in force, it will be on a large scale, and it will, therefore, be a great benefit to have the participation of foreign markets, as in the case of the late participation of the Paris market, which gave opportune relief.\*

\* It is impossible to quote all that has been written and said on Indian coinage. Before the Society, in this Indian Section, valuable papers have been read by Col. J. T. Smith, and have been stoutly contested. What can be read with much benefit is,

The chief points that are brought forward in this paper, are—That by traditions and history gold is known to be produced in Southern India; that the extent of the formations has been proved by successive explorations; that for the working of these formations there are to be obtained labour, water, timber. The effect of the production of gold has been explained with regard to currency and exchanges, and prices.

VII. In closing this paper, I must renew my acknowledgments to many who have assisted me, and whose names I have quoted, Mr. B. Brough Smyth, Mr. Samuel Jennings, Mr. W. J. Rhodes, Mr. Juland Danvers, Col. J. T. Smith, Mr. Andrew Casela, Sir W. Rose Robinson, Mr. Claremont Daniell, Mr. James Wyld, Mr. R. Palmer Harding, Professor Badlar, Mr. O. Pagler.

#### DISCUSSION.

Mr. W. D. Fowles said he had little or no experience in Indian gold mines, but he had experience in other parts of the world, and a word or two with respect to the profitable use of tailings from gold mines, which had previously proved unprofitable, might be of some interest as illustrating gold mining in general. His family bought the tailings of a mine in Colombia, which had been worked for the free gold alone, having made a contract to take them for 12 years for 50,000 dollars, whereas, until then, they had to be thrown away as useless. They erected a small furnace in a very rough way, and from those tailings produced a profit of three or four thousand dollars a month. Not long afterwards, his father sold his share for 165,000 dollars. Of Indian gold mines, he only knew what he had read of Mr. Brough Smyth's reports, and what he had seen at the School of Mines; and he knew, from the geological formation, that quantities of gold must exist in the quartz reefs; that there was no doubt about. The only question was whether it could be obtained at such a cost as would show a profit on the working. He regretted that the enterprise should not have a fair start, the amount of capital on which dividend would have to be paid being rather heavy. Even supposing it to be a *bona fide* operation, the profit on the actual working expenses would have to be rather large in order to show a profit on the whole capital—he meant at the commencement, because he had no doubt that later on, when the proper appliances were imported, in order to produce the gold at its minimum cost, they would be able to pay a dividend on a much larger capital, but he regretted that it should be rather heavily handicapped at the beginning. His experience had been chiefly in the United States, in Colombia, and in South America, in both gold and silver mines, and, on another occasion, he should be glad to discuss both the mining and smelting of gold and silver ores.

Mr. Leek wished to say, in connection with Mr. Hyde Clarke's observation that the capital invested in machinery was the real capital, that that showed how important it was that the machinery should be of the very best description you could possibly have for the purpose, and in order to that, there must be suitable knowledge of what was required. A short time ago he had made the suggestion, from the ignorance which seemed to prevail on this subject, that this country wanted a Gold Institute, where the different appliances requisite for the proper treatment of gold ore could be

examined, their merits tested, and the whole so thoroughly ventilated. Gold mining was a science, must be studied like any other science. As Mr. Clarke mentioned, suitable and unsuitable appliances already been used in India. Mr. Brough Smyth's report referred to a company started some time ago Alpha, which sent out some machinery with which quartz cropping out on the top of the reef was cut; it therefore must have contained all free gold should have been the very easiest material to deal with. But so far from getting gold, they lost a mercury, and the company came to grief, not because there was no gold in the ore, but because the apparatus used to get it out were of no value. Within three or four months, he had seen some machinery was being sent out for some company or private India, which he was perfectly certain could run out more than 50 per cent. of the gold in the ore mining in India was not only of importance country, but to all the world, because every ounce wherever obtained, became a circulating medium induced an extra trade, and passed all over the world. Within the last 25 years, they had seen a large increase in exports and imports, which had entirely arisen from the vast gold discoveries in Australia and California. If there had been no gold discovered, that trade could not have been carried out. It became, therefore, a matter of great importance to every country, not only gold should be got out of the ore, but also that as much as possible should be got out. Gold mining was one of the first enterprises which opened up any country. Without gold mining, California would have done much, and, certainly, without it, America did not make much progress; but the moment gold was discovered and worked, other industries followed the country became developed. He did not see what had taken place in Australia and California, and not in like manner take place in India. Works would be created which did not now exist, which would be further capital, and the country would take a totally different start. He was therefore most desirous to see that company which entered into gold mining in India, should be, as far as possible, a success. They had to thank Mr. Fowles for a most important statement, which showed that the knowledge of one man might make as much where the want of knowledge of the previous generation made a failure. They wanted men like Mr. Fowles. It seemed to him that knowledge could not be obtained unless there were some means taken, such as he suggested—the formation of a Gold Institute, where the knowledge gathered together information from all over the world, and which could, in its turn, be redistributed all over the world.

Mr. Thomson asked what, in the opinion of the Government, was the district, was now considered the area of the gold field? This was an important question with reference to the great question raised in the paper, as to the probable great monetary and political effects of the re-discovery of gold. If, as he was informed, it was now certainly 500 miles, he wished to know to what extent this field could now be said to extend. If the district of Mysore were included, as well as the district of Wynad, would it not be right to say there was a very large territory now fit for its habitation. The success which his own country had in importing Cornish miners, had given him the idea that we might have eventually a very large portion of Cornish men or Australians permanently settled in the hill districts of India. If he were there would be a means of very seriously affecting the future of India in the charge for the army, because you had a large European colony in the hill districts that colony would very easily be attracted still by military service, and you would get a permanent resident population, which would very much aid

"Gold in the East" (London: Strahan & Co.), by Mr. Claremont J. Daniell, B.C.S., of Madras, who has treated the question in a masterly and practical manner. In the appendix is an extract from General Daniell, Mint-master at Bombay in 1890. Mr. Samuel Jennings has dealt ably with the relations of gold and currency. (*Barro's Journal*, 6th Dec., 1899.)

fifteen millions now spent annually on the Indian Army. Mr. Lock would very much add to the value of his observations, if he could suggest the best form of machinery. There was no doubt that some of the old-fashioned machinery had been sent out, but to what extent it was so, they would all be glad to learn. The suggestion of a Gold Institute would, he believed, be welcomed by all interested in the subject, and the question he should like to ask was, whether something could not be done with the crushed quartz; he believed it contained a large quantity of silica, and it struck him it might be used in some way to advantage in cultivation.

Mr. Maxwell Lyte said the principal cost of treating gold was the labour. Although he had not been in India, he had read a good deal on the subject, and he should be glad if Mr. Hyde Clarke could throw them a little on the question of labour. The introduction of Cornish miners had been referred to, and he doubted if English labour could be got to work in such a climate.

Mr. Friessway Saunders said he was not in a position to speak on gold mining, but he might make a remark on the question raised by the previous speaker, namely, the suitability of Wynnaad for colonisation by Cornish miners. He could only say he thought it would be very difficult to persuade them to work in a climate which involved a rainfall of something like 200 inches.

A Member said the rainfall all took place in three months.

Mr. Saunders said he did not intend to discuss that question, but there was no doubt that was something like the annual rainfall of the country, which had to be endured, whether it all came in three months or not. He viewed the progress of this speculation with great anxiety. They all knew that the subject of gold mining was not a new one, for it had been before the attention of that Government for the last years. So long ago, the investigations made under Mr. Nicholson and others were not thought of as encouraging to be proceeded with. At the same time, there could be no doubt that India had produced large quantities of gold; and the encouraging fact he had heard, if it were a fact, was the result of the removal of a pillar from the old workings in one of these Wynnaad mines, which was found to be very productive. As to the question of the earlier productiveness of India in gold, there was not much evidence; but there were probabilities, and there were also probabilities of the condition of labour under which gold mining was profitable to the former rulers. Supposing Tippoo Sahib produced large quantities of gold, there could be very little doubt as to the way he would have gone to work. He would have employed large numbers of men under strenuous directions, regardless of life, or any of those considerations which had to be very carefully attended to by an English Government. Under such conditions, it may have been practicable to remove mountains, or conduct any operations with a greater amount of labour and a less amount of expenditure for labour than would be possible now. The question now was whether the introduction of machinery and the application of European skill would be a substitute for that plethora of labour which a Hindoo conqueror could apply. He hoped that skill and machinery would be considerably unbalanced by the large amount of capital with which the interests of the money market and speculators might find it necessary to load every undertaking into which they entered. This was becoming a very serious question, and was one to be regarded by all serious students of business as one of the first importance, and he felt some effort ought to be made in the City of London to put down this ruinous practice, which did to overload and destroy the profit of any

undertaking by the excess of capital imposed upon it. He said this, not with a view of counteracting the operations of these gold-mining companies, for he should be exceedingly thankful for their success, because he could see that if so, they would encourage other operations in other directions, which must greatly tend to the advantage of the people of India, as well as of Europe. He saw already symptoms of the increasing investment of capital in legitimate trade in India; and there was one thing to which we could point with pride in connection with our occupation of that country, that while we took upon ourselves the responsibility of ruling it, we excluded nobody from any good to be got out of it. It was that which gave us a claim to the consideration of other mercantile countries of Europe.

Mr. Christian Mast, as a teacher, hoped that the important question of technical education, in connection with this subject, would not be lost sight of, for there was no doubt that the success of these operations would depend in a large measure on the amount of intellect and investigation brought to bear upon them.

Mr. Dipnall said he came, probably like some others, as a mere learner, and the title of the paper gave no idea of how the subject was going to be treated. Mr. Hyde Clarke had treated it mostly from the productive, and political and social points of view, whilst the map had explained pretty clearly the topography of this particular rediscovery of gold mining; and when he heard the observations of some gentlemen who had spoken, and noticed on that map that the mining operations would be conducted in 10 degrees of north latitude, it showed to his mind that they would be conducted in a climate totally unfit for any great body of Cornish miners or other Englishmen. It struck him, therefore, that they must look either to native labour, or labour imported from China, and that they would not be justified in settling down in such a district a large body of European labourers. He would also suggest that when the rainfall was stated to be occasionally something like 300 inches in the year, or 10 times the average rainfall of this country, even if it fell in three months, the three months of deluge and nine months of arid weather by no means presented a climate suitable for the residence of Englishmen. It was, therefore, of the utmost importance that every possible inquiry should be made before any large number of Englishmen should be introduced there. With regard to the development of gold in India, there could be no doubt whatever, looking at the great mountain ranges, that gold did exist there to a large extent, and that, as in the case of copper and other minerals in ancient Greece, the imperfect manner in which the ores had been treated in former ages had only allowed less than half the products to be got out, leaving a large balance for future generations. They had recently heard from Sir Bartle Frere, that a similar observation applied to the imperfect mode of extraction in South Africa, there being as much left behind as was taken out. Some excellent allusions had been made to the mechanical part of the operations, and the question of improved machinery, but he did not think enough had been said about the chemical part or process, and how, by greater attention to that point, modes of extracting gold might be discovered which would produce it at a much cheaper rate. It struck him, without pretending to any scientific knowledge, that with the wonderful development of electricity going on, modes might be found of fusing gold which had not already been used, and this particular opening in India might present a field of operations, whereby, without the employment of enormous labour, European skill and science might be so directed, as that by a minimum of effort the greatest amount might be produced.

Mr. Andrew Cassels said the last two speakers had forestalled a great deal of what he meant to say. He agreed with the last speaker as to the unsuitableness of

the climate for English labourers, and he also shared the opinion of Mr. Saunders, that this matter had been very much overdone in London lately. He had glanced at the paper before coming, and was much pleased with the impartiality with which Mr. Hyde Clarke had dealt with the subject. What one gentleman had said about the imperfections of much of the machinery sent out was quite true. He had had a great deal of information privately from gentlemen connected with the districts, he had seen many reports and specimens of the quartz sent him, and his strong impression was that there was great disappointment in store for those who had embarked in this enterprise. Although he ventured to say this—and it required some little courage to say it in the face of strong opinions held by many gentlemen for whose opinions he had great respect—no one would be better pleased than himself if these golden dreams were realised. He greatly approved of the sentiment in the latter part of the paper, where the writer spoke of the effect of the great discoveries of gold upon India and on the exchanges, matters which had come home to most of those connected with India lately with startling effect. To speculate on what would be the result of large discoveries of gold, was at present scarcely possible. The great fluctuations they had seen in the last 12 or 15 years, in the value of silver, taught one to be cautious. Fifteen or sixteen years ago, there was a great agitation in India, chiefly originated by his brother, Mr. Walter Cassels, in Bombay, and by Sir William Mansfield, with regard to the introduction of a gold currency. Their arguments were, at that time, chiefly founded upon the fact that silver was scarce, being then 63d. per ounce, instead of 51d., as at present. They wished to introduce a gold currency, and he himself held much the same opinion. In that room, he read a paper bearing upon the subject, but since then silver had fallen so much in value that it was impossible to say what would happen. Let them see what the gold discoveries, and the result of the conference to be held in Paris in next April, would do for silver. It was pretty clear something would be done, and he indulged the hope that they would see silver regain some of its old value, and not remain, as at present, a great loss to the Indian revenue, and to every man toiling in India under a blazing sun, and the wife and children at home, to whom he had to forward a considerable portion of his earnings. There would be no greater benefit to Englishmen connected with India than to see some improvement in that respect.

Mr. Woolley said he was well acquainted with the district, and had some knowledge of gold mining, having visited other gold countries. He begged, with all possible respect to Mr. Hyde Clarke, to say that in this case the companies which had been formed had commenced, not by sending out the machinery, but by providing themselves with raw material. No doubt they had done it to an extent which perhaps in private life would bring them to bankruptcy, but the greater part of the capital which had been raised had been sunk, not in machinery, but in providing the raw material upon which they must operate, and from which they hoped to extract satisfactory results. As far as his own opinion went, if skill were brought to bear, the results would far exceed anything ever seen in Australia and California, but it all depended upon that. There was, therefore, every requisite. One of the gentlemen had spoken about rainfall, but he was in India last year, and the rainfall, instead of being 300 inches, or even 200, did not average 100 inches. 200 was quite the maximum. And the Cornish miners, even if they were there, would only be exposed to the rain during their passage from their quarters to the works. He quite agreed that to send any quantity of English labourers to 10 degrees north latitude would be an absurdity, for the climate was unsuitable to a European working out of doors. But those who worked the mines

would not be out of doors, and would not feel the sun. There was, however, no great use of Cornish miners there. There was every first-class labour to be had on the spot; industry, as far as it had gone, had the price of labour at all. If it had affected his pocket, as a large one. The supply of labour was almost inexhaustible; there were great muscular fellows then capable of doing any amount of work, a miners almost by birth, who were ready for 7d. a day, without the slightest hesitation. One wanted of Cornish miners, was the skill to intend this labour and, bring it to bear it as to produce satisfactory results, and the such skilled labour need not be much. A large area, he believed that at present the area of the colony of Victoria was 1,400 square miles, whilst the known auriferous Wynaad alone was twice that. The Victoria had, two years ago, over 800 mines in operation, and in India we had now at the utmost, 25 or twice the area. How could then that the companies were too many, were almost certain to come to grief. The prospect of such a thing, if only proper advantages were brought to bear.

The Chairman said he would not detain long, because the several gentlemen who had subject had pretty nearly exhausted it, but confine himself to two or three practical points. The area of possible gold-field. He could speak on the area along the Eastern Ghats seemed to exist in the Ghats on the peninsula. The Mysore gold-fields were the verge of the Eastern Ghats. The Wynaad he knew much better, having been in the country since 1842, and knowing it all very well. He noticed what Mr. Brough Smyth said to the effect that not one-twentieth part of the gold area had been prospected in any direction. There were some gold washing in streams and rivers all along the ghats in Canara, and in the whole way, almost to Cape Comorin, but they might accept it, that for the present that part of Wynaad now attracting attention, continue to be the nucleus of the work question, doubtless, was a very important one. Woolley, whom he knew to be a practical labourer in Wynaad, had given some very encouraging facts as to the present condition of the labour market, but what would be the development of the gold industry based on that industry, was very uncertain. In the Wynaad there was no doubt that the gold industry started on the coast of India, as respects labour, in a better position than in any other country. You started with a teeming population, who would afford all the labour which would be required at the present. Wages, however, would have to be taken into account. Within the time in India, the price of labour had certainly risen, and a large increase in the demand must effect upon it. He was glad Mr. Cassels had called attention to the caution required in this question, and he himself felt some anxiety on the fact that the companies were going on, handicapped by the large prices paid for labour. He thought that, beyond the question, the importation of large numbers of labour would not be requisite or desirable. He would follow Mr. Hyde Clarke into the interest of coinage and exchanges in India. He had doubts whether a poor country like India could practically use a gold coinage for its own. One fourth part of the population

was practically bartering grain they raised or for such commodities as they used, or used shells as tokens; the country was a very poor one, and it was doubted whether, being in such a condition, it could float a gold coinage. Any way, as Mr. Clarke said, they would have to mint the gold in some other, and then it would be practically decided that such a coinage would be a useful form of their currency. He observed that the proper alignment of the connection between the Wynaad and the Mysore system of South India lies through the Muddebichur (Moyar valley) district, and thence *via* Bandipur, Mysore and Bangalori, whence was derived the supply of grain and labour, and not over the Nilgherry hills to the Coimbatore district by the Kunur valley. The so-called Alpine railway up the latter valley would be mere waste and delusion.

Mr. Hyde Clarke said the necessity for a reply was much less than it appeared, because several of the points raised had been already dealt with by him in his paper, as would be seen on its perusal. Beyond that, the necessity of his giving a detailed reply was dictated by the nature of the discussion, and he stated at the outset, that he was much more anxious to have the benefit of this discussion, than to forward any views of his own. It had been his advantage, not only that they had men taking interest in it, well acquainted with India, and deeply experienced in it, but men of very wide experience in the arts of the world. In fact, there was hardly a district in the region which was not represented there in person, or by the presence of some one practically acquainted with it. Mr. Woolley, to a great degree, covered some of the other speakers, but he thought they had misunderstood him on one or two points, when they came to compare notes, they would find in substantial agreement. There was no question of the employment of a large amount of European labour. The great advantage of the Indian region was that it had a large supply of labour, but at the same time they did want skilled labour. Some gentlemen seemed to think it was inferior to a Cornishman to go to a country of that sort, or one which had a large rainfall. But it was a very great advantage to gold working; in reference to the climate, he would remind the Cornish miners went to very much worse climates than India. Some of Mr. Woolley's neighbours in the Wynaad, although that was an unhealthy region, had remained the whole of the year on their plantations, so that it could not be altogether so fatal. They must, however, recollect that they were not going to work on the surface, but underground in case of reduction operations, under shelter; and by no means necessary he should be exposed to the elements of the year. In such cases the white men, unacclimatised, went somewhere else, and it was an advantage in this case that there were some healthy districts in the Nilgherry hills where they could go. On a careful and candid consideration of the paper and the discussion, he thought that the merits of the objections would be removed. He had brought forward many important facts which must not be left out of consideration. He thought they would all see changes in the relative value of silver, and what Mr. Cassels had said to him a reason why they should look at this matter cautiously and not distrustfully. In the past he had been careful not to encourage share speculation, but at the same time to ask them to look at the possibility of practical results being obtained. He thought they go by the experience of those practical men present, and who knew what the resources of the country were, than of the suggestion of a mere doubter. On his own part, he looked upon it that disastrous results would take place; but they had no duty, for the gamblers who chose to put their stakes on the

table, to stop legitimate operations. Why were they to protect men who had gone in for gambling? The present condition of the share market, with regard to Indian gold companies, in his firm belief, was nothing to what they would yet see. For two years he had foreseen that in all likelihood there would be a gold mania, and that speculation would take the form of gold mining. If so, they would see reproduced what they had seen before, these shares would run up to fabulous premiums; but what had that to do with gold mining? They could not prevent such a thing. These men were gambling with counters; men were putting their money into gold mining shares who would stake their money on the Derby, and were they to protect them in either case? Why should they stop the whole operations of the empire for the sake of persons of that kind. What they had to look to were the persons really interested—the population of India, whose welfare was at stake. One point referred to by Mr. Lock and himself was the effect produced on a district by the introduction of mining machinery. To illustrate that, in the *St. James's Gazette* of that evening, there was a paragraph with regard to the Linares lead district in Spain. It was stated that in consequence of the great increase of lead mining, the Belgian manufacturers had supplied a large amount of machinery, the result of which had been that they had been called upon to supply machinery likewise, for the oil industry of the district, and the people there were giving up the old clumsy wooden presses, adopting improved machinery, and turning out a better article in olive oil. That supported what he had stated in the paper, that they should be justified in looking at the collateral advantages which would undoubtedly arise, apart from any mining results. The evidence of practical men showed that there was a great gold region in Southern India, and nothing but the grossest imbecility could prevent very large results being obtained.

The Chairman moved a vote of thanks to Mr. Hyde Clarke, which was carried unanimously.

Some specimens of gold were kindly lent for exhibition at the meeting by the Wynaad Company, Professor Tennant, and Mr. Bryce Wright.

#### ELEVENTH ORDINARY MEETING.

Wednesday, February 16th, 1881; W. H. HALL in the chair.

The following candidates were proposed for election as members of the Society:—

Branston, F. R. E., 23, St. Swithin's-lane, E.C., and 66, Lillieshall-road, S.W.  
Dollman, Charles, 293, Clapham-road, S.W.  
Greenwood, A., LL.D., Flaxfield College, Basingstoke.  
MacCallum, Andrew, 47, Bedford-gardens, Kensington, W.  
Wilding, Samuel P., 23, Rood-lane, E.C.

The following candidates were balloted for, and duly elected members of the Society:—

Bridge, John, F.R.G.S., Marlborough-house, Sale, near Manchester.  
Cochrane, Vice-Admiral the Hon. Arthur A., C.B., United Service Club, S.W.  
Collingwood, Lieut. William, The Limes, Cheshunt, Herts, and India-office, S.W.  
Fisher, John, 43, Mincing-lane, E.C.  
Hall, William Shippery, 79, Cannon-street, E.C.  
Haslam, Alfred Seale, Duffield-road, Derby.  
Helder, Augustus, Corkicle, Whitehaven.

The Chairman, in introducing Mr. Taylor, said his only title to preside was his having had the good for-

time to bring to light afresh the most remarkable instances of industrial partnerships—that of Mr. Leclaire, on which a pamphlet, written by him, had just been published by the Co-operative Wholesale Society. The remarkable feature of that enterprise was that, nearly 10 years after the founder's death, it still went on in a more flourishing way than ever. It was the whole object of Leclaire's life that the scheme should not be dependent upon him, and, during the latter part of his life, he withdrew as much as possible from the active supervision of the business. The success had been most wonderful, and the same principle had been followed in several other instances on the Continent, but, unfortunately, in England such attempts had not hitherto turned out well. Many might remember the attempts of Messrs. Briggs, Messrs. Fox, Head, & Co., and others, but they had not the elements of durability. Why this should be so, he was at a loss to understand, because the system was one which eminently commended itself to common sense or enlightened self-interest. Leclaire began life as a labourer, and noticed the wasteful habits of labourers. As he got on in life, and became an employer himself, he asked himself the question if nothing could be done to remedy this state of things, and came to the conclusion that the only way was to give the workmen themselves an interest in greater thrift, carefulness, and industry. He thought that if 6d. a day was saved in this way, and the workmen received 1d. of it, and the employer 4d., the plan could be adopted, and this proved to be the case. In this way a large fund was accumulated out of nothing. He had a suspicion that one cause of the non-success of the plan in England, was the opposition of trades unions. These organizations had done great good in some respects, but he feared that in some cases they had opposed enterprises of this kind, which had been essayed by men not in the union, and of which the union leaders were jealous, because they were not concerned in it themselves. He threw out the hint that this might be the cause, because he knew that in France, employers came more directly in contact with their workpeople.

The paper read was on—

## THE PARTICIPATION OF LABOUR IN THE PROFITS OF ENTERPRISE.

By Sedley Taylor, M.A.,

Late Fellow of Trinity College, Cambridge.

I ask attention this evening to a particular method of remunerating labour, which has for some time been practised in a large number of important industrial and commercial establishments, situated for the most part in France, Switzerland, and Germany. If any justification is needed for bringing this subject before the Society of Arts, I find it in the following considerations:—The relations between employers and employed, under the system of payment by fixed wages only, are admitted on all hands to be unsatisfactory. They involve a chronic antagonism, breaking out periodically into internecine conflicts, which leave few tangible results behind them, save extreme mutual exasperation. One is reminded of the old school-game of French and English, where a great expenditure of force in tugging at the opposite ends of a rope has for chief result a marked rise of temperature, where in fact, as in an ill-constructed machine, energy is converted mainly into heat.

The evil of a permanent antagonism between men engaged in one and the same branch of production or distribution, has induced a number of employers to try whether by modifying the

established method of remuneration by w only, they could bring about a better state things. The bulk of these experiments been made on the Continent, and, though without examples of failure, they present, a whole, a very decided and very encouraging success. This being so, the close connection which links together the industries of neighbouring countries makes it incumbent on employers to bestow vigilant attention on a movement of such importance as a considerable movement towards a reform in the mode of remunerating labour.

While, however, I feel that the nature of the subject is its own best justification, I am yet aware that one who, like myself, is no employer of labour, and, consequently, has no profit to divide, may, when he urges such divisions to those who have, be damagingly compared to certain hearers of a charity sermon, who, according to Sadey Smith, found his greatest emotions so stirred by the eloquence of the preacher, that he put his hands into his neighbour's pockets, and was thus enabled to place a liberal contribution in the plate. In order to the point of this dangerous comparison, I feel, without professing an impartiality which I do not feel, endeavour, as far as possible, to set out facts on which I rely, in the statements, often the actual words, of employers describing the results of experiments which they have themselves made. By placing before you their statements the most authentic and least warped form of command, I hope in some measure to make up my own lack of business knowledge and business experience.

The mode of remunerating labour which I to engage our attention consists in assigning the employed, over and above their wages at the ordinary market rate, a part of the net profit realized by the concern for which they work. The system is known in France as "*la part aux bénéfices*," i.e., participation in profits, shall, for shortness's sake, designate it in this simply as "participation."

The economic basis on which the method may be thus stated:—The profits realized by industrial establishment must largely depend on the degree of vigour and vigilance with which hands in its employ perform their work. Economy of time, and avoidance of needless consumption of raw materials and destruction of tools and machinery, will lead to higher profits than idleness where dawdling, waste of materials, recklessness in handling implements and general sloth are the order of the day. Now, the established practice of the workshop shows that, under the system of payment by wages alone, it is not expected that this zealously active type of work will be done voluntarily. Watchmen and overlookers are there, in order to extort, by the fear of dismissal, whatever quantity and quality of work is obtainable by an appeal to such feelings.

Work thus reluctantly yielded will, manifestly, be inferior at all points to that given voluntarily. It will therefore be dear work, and tend to diminish profits, which will be further preyed upon by the wages of the overlookers employed in exacting it, in other words, by the "costs of supervision" which it entails. The exasperation of the

participation was that, under that work of the most zealous kind would be soonly given, when once the workmen had fully alive to the fact that their more efforts would directly benefit themselves. And, and therefore cheaper, work would be done, and the costs of supervision be proportionally reduced. It is in the additional profits to be secured by these stimulated efforts, and in the power in superintendence which they render, that participation finds the fund which it is to divide. The employer is, therefore, bound upon to forego any portion of the profits which would, under a non-participating system, have been added to him.

As to the manner in which the workmen's share in profits is made available by them, there is among participating houses very wide variety of practice; indeed, these differences afford convenient means of classifying such systems. They fall into three categories:—

1. Those which pay over the workmen's share in annual ready-money bonuses.

2. Those which retain that share for an assigned period ultimately to apply it, together with accumulated interest, for the workmen's

3. Those which annually distribute a portion of the workmen's share, and invest the remainder.

As to the manner in which the workmen's share is to be taken out of each year's type-specimen. It will be readily seen that limits of time will compel me to restrict my organization only in the most general manner.

As to the sources from which my statement will be drawn, I can here only name the chief. These are:—(1) A German system published in 1878, by Professor Böhmert, under the title "Die Gewinnbetheiligung," "Division of Profits." (2) The participation of a French society, formed in 1879, giving the practical study of participation, the work of M. Fougereousse, "Patrons de Paris," "Masters and Men in Paris," in 1880.

In the preliminaries, I begin with the group which hand over the workmen's entire share of profits in annual ready-money bonuses. I take as type-specimen the establishment of M. Lefort, maker, 64, rue des Poissonniers, where participation has existed in that house on the following basis:—At each annual interest at 10 per cent. on the capital, the business is deducted and handed over to the proprietor, M. Bord. The remaining profits are then divided into two parts, respectively proportional, the one to the interest added to capital, the other to the whole which has been paid during the year in the current market rate. The former is added to M. Bord's receipts; the latter is among all such workmen as have been employed by the house for not less than six months in question. The individual distribution of bonuses proportional to the yearly net earnings of each workman in wages, and dividends to labour are handed over without limitation or condition whatever. The

number of *employés* was, on January 1, 1878, 6 clerks, 395 men, and 27 boys. The sums thus paid during the last three years were, I am informed by M. Bord, in 1878, £3,784; in 1879, £2,874; and in 1880, £3,548. They represent, respectively, 15 per cent., 12 per cent., and 16 per cent. on the men's yearly earnings in wages. The entire amount paid over, exclusively out of profits, since the introduction of participation in 1865, is £39,300. M. Bord considers the effect of the system, in attaching the workmen to the house, and its influence on their relations towards their employer, to be extremely satisfactory. In June, 1869, he ascertained that about one-half of his workmen had invested their dividends for that year, and that about a quarter had employed them in clearing off debts, and in purchasing clothes and furniture. A dozen or so only had dissipated a part of their dividends.

The number of houses which adopt M. Bord's system of immediate cash distribution is very small. I pass to a larger group, organized on a very different plan. The example selected is a leading Parisian Insurance Company, the *Compagnie d'Assurances Générales*, 87, rue de Richelieu.

In this company, whose staff of officials, clerks, and other *employés* numbers about 250 persons, participation is now of thirty years' standing. It is fixed at 5 per cent. on the profits of the company, and allotted in proportion to the individual salaries earned, which are at least on a level with those obtainable in non-participating companies of the same kind. The essential feature of the system here in force is that no part of an *employé's* share in profits is paid over to him in ready money. The sums to which he becomes yearly entitled are placed in a deposit-account opened in his name, where they accumulate at 4 per cent. compound interest. Only on the completion of 25 years of work in the house, or of 65 years of age, can the beneficiary claim the liquidation of his account. The following alternatives are then at his choice:—He may purchase a life-annuity in the company's office, with reversion to his widow or some other person to be approved by the Board of Directors; or he may invest in French Government or railway securities, in which case the stock certificates will be retained by the company until his death, in order to be subsequently handed over to the persons whom he may designate by will as his heirs. He cannot claim the payment of his account in ready money, the Board of Directors being sole judges of the exceptional circumstances under which they may consent to such payment, and not bound to assign any reason for their decision.

M. Alfred de Courcy, to whom the *Compagnie d'Assurances Générales*, of which he is the managing director, owes this particular form of long-deferred, indeed, one may say, of testamentarily transmitted, participation, has publicly advocated it with great eloquence and ability. He insists on the relatively large sums which it has accumulated, in comparatively short spaces of time, for *employés* of the company. Thus he specifies a simple bookkeeper, in whose name £480 stood to the good after fourteen years of work, a sub-cashier with more than £800 after 25 years, and a superior official with £2,600 at the end of a similar period. The results to the company itself are described in the following passage, which I

translate at second hand, from the German version of the original given by Böhmert:—

"The bond which unites the company and its *employés* has acquired a peculiar strength. Formerly, notices of resignation were very numerous. Among the young people, caprice, levity, and infirmity of purpose were often the cause of this. On the occurrence of the slightest annoyance they became intractable, and withdrew, or worked negligently, while they were looking about for another post. In the case of the more practised and experienced *employés*, personal interest was the decisive motive. New insurance companies were called into existence, the founders of which naturally sought for people who were not novices, and possessed special acquaintance with our business. Where were such men to be found, unless in the staffs of the old insurance companies? We, therefore, frequently had our best *employés* carried off by the promise of a higher remuneration, in order that they might make use elsewhere of the knowledge acquired with us, so that we actually furnished the weapons for a competition directed against ourselves. To this disorder, and this withdrawal of *employés*, which threatened to injure our organization, the deposit account has put an end. It is so highly valued, that the sacrifice of the benefits of participation for a momentary advantage is not readily made. It has rendered even the young people more steady and assiduous. The faithful *employés*, too, have become more hardworking, not merely because they know that they have a joint interest in the success of the business, but because it is an advantage for them that the number of the staff should not be increased. At the time of heavy pressure of business they are, therefore, willing to redouble their activity, and, if necessary, to stay over-hours at the office. Their own interest is the best guarantee for their zeal. The limitation of the number of *employés* to what is adequate, and no more, is an important source of saving to the company."

M. de Courcy is so high an authority on all matters connected with participation that I desired, for the purposes of this Paper, to ascertain his latest view on the subject. I accordingly asked him to tell me whether his opinion, both of the principle of participation itself, and of the system of deferred possession, remained as favourable as at the time of the publication of Professor Böhmert's work. In his reply, dated November 6, 1880, M. de Courcy writes as follows:—

"My present opinion is more favourable than ever, both to the principle of participation, and in particular to my system of deferred possession. The institution has now had thirty years of experience, that is to say, of unvarying successes. Each year, by augmenting the account of the *employé*, makes him feel more strongly the advantage of the deferred participation. Each year, too, the company appreciates better what it gains in fidelity in return for these sacrifices. My general principle is that there are no thoroughly satisfactory business transactions except those which are satisfactory to both the parties concerned. Experience has justified our institution from each of these points of view. It is excellent for the *employés* and excellent for the company."

The great majority of participating houses have favoured neither the entire immediate distribution of profits practised by M. Bord, nor the extremely remote postponement of benefits advocated by M. de Courcy. They have adopted a mixed system, by conceding to the workman immediate possession of a part of his share in profits, and investing the remainder for his future benefit. Of the establishments which have taken this course, I select as example the great railway

printing, publishing, and bookselling house M. A. Chaix, 20, rue Bergère, Paris, who once the "Bradshaw" and the "Right Hon. H. Smith" of France, and who employs 600 persons of both sexes. Participation from 1872, and extends to all well-conducted hands who can show three years of continuous presence in the house. The share assigned them is separately fixed each year, but has been 15 per cent. on the net profits. The amount allotted to each participant, which is proportional to his or her annual earning in wages, is divided into three equal parts. One of these is paid over on the spot in cash; a second, regarded as the property of the recipient, is placed in the custody of the house, in order to support its provident society; the remainder is likewise placed to the credit of the beneficiary but only comes into his possession at the age of sixty, or after twenty years of uninterrupted service for the house.

In regard to the ultimate disposal of the second and third parts, regulations subsist similar to those in force in the *Compagnie d'Assurances Générales*.

The total amount allotted by M. Chaix to his participants, from 1872 to 1880, was £14,409, which represents an annual average of 7½ per cent. on the wages of the beneficiaries one-third of this average, i.e., 2½ per cent. on wages, was, however, as has been already explained, yearly distributed in ready money. In regard to the general results of participation in this house we have the testimony of M. Chaix himself, addresses which he has delivered to his participants at each of the seven yearly distributions which as yet taken place.

I will translate a few extracts from these, and speak for themselves.

At the second participation, on April 3, 1875, M. Chaix said:—

"I have ascertained with satisfaction that the introduction of participation has, as I hoped it would, developed the zeal of those interested in it; as it takes more interest in the work assigned to it, and executes it better and more expeditiously."

On March 28, 1875, he spoke as follows:—

"If there be a spectacle which should satisfy the friends of social peace, it is assuredly that presented by the industrial family of this establishment, when, at the completion of the year's work, it is gathered together in order to learn the results of its own labours, and the profits realised. No institution is, indeed, so well adapted to draw close the bonds which unite the workers to the house, and to inspire you with confidence in the management, than the participation which has enabled me to do so for your benefit, not only certain immediate advantages but also an economized capital, which has, in among you, already reached important dimensions."

The address of April 13, 1879, contains the following passage:—

"In what concerns the execution of work in the workshops and in the offices, I find around me a great amount of willing zeal, that I give the main credit for this excellent state of things to participation, and I congratulate myself more and more on having a principle working in the house."

\* Comptes Rendus des Assemblées Générales Annuelles de la Chaix, 1880, p. 33.

‡ *Ib.*, p. 73.

three categories, of each of which one has now been given, include all houses of what has been termed simple participation, that under which the participants are no voice in the administration of the concern which they work, and own no part of the embarked in it. There are, however, a few which admit their workpeople to partnership in capital, and to a share in administration. These establishments are specially distinguished, not only on account of their individual nature, but because their organization may be said to mark the point of transition from participation, where the master retains exclusive possession of capital and control over the co-operative production, where the capital belongs to the associated workmen, and business-direction is in the hands of a manager or committee acting under their authority. Each of the small group of houses occupying this intermediate position is well worthy of special study, but where, as this but one of them can be described, the Maison Leclaire, at Paris, is incontestably to be selected as the representative of the type. It is a house-painting and decorating establishment, 11, rue Saint-Georges, and employs upwards of one thousand workmen. The founder, born in 1801, the son of a poor workman, and apprenticed in 1818 to a house-painter, had, by 1834, already attained a position of distinction and assured success as employer of labour in that branch. From the first, he practised participation in profits, and with his steadiest and best-conducted establishment and gradually extending the system to others. In 1853, Leclaire established, among his workpeople, a "Mutual Aid Society," to be exclusively out of the profits of his business, his society which, until 1860, only performed the functions of an ordinary sick-club, thenceforth to supply retiring life for its members on their superannuation from work. In 1864, the same society was, by an irrevocable deed, constituted sleeper in the house, and owner of a considerable portion of its capital. Five years later, in 1869, Leclaire took the final step of transforming his establishment into a permanent industrial concern, the net profits of which, after deduction of 5 per cent. interest on capital, were to be divided in the following proportions: one-fourth was to go to the two managing partners who were at first to be M. Leclaire and his associate, M. Defournaux. One-fourth was to be distributed in ready-money to labour, and the remaining quarter to be paid over to the Provident Society for its old-age pension fund. The business-direction, however, i.e., its actual executive, was to remain exclusively in the hands of the two managing partners for the time being. To the members of the Foundation were, however, very considerable powers, to be exercised through two committees, one for the management and the other for the "Society," on both of which the labour would have a predominant representation. These two bodies, with their electing members, were to choose the managing partners and foremen, admit new members, expel

grave misdemeanants, administer the funds of the "Society," and see that the share of profits annually due to it from the "House" was fully paid over.

Leclaire did not long survive the definitive incorporation of his house. He died in 1872, and in 1875 death removed his successor, M. Defournaux. The present heads of the establishment are MM. Redouly et Marquot, the latter of whom was private secretary to Leclaire. M. Charles Robert, *conseiller d'état* under the Empire, who from his boyhood was strongly attached to the founder, succeeded him as President of the Mutual Aid Society, and, though now charged, as managing director of a great Parisian Insurance Company, l'Union, with engrossing administrative work of his own, has never ceased to be the staunch and untiring friend and counsellor of the Maison Leclaire; advocating its central principle with a ready pen, and standing forth, with eloquent tongue and cultured utterance, as its mouthpiece on every occasion of corporate weal or woe, whether to cheer on its members with the good news of continued and increasing prosperity, or to pronounce in their name, as they crowded in hundreds around him, words of final leave-taking at the open graves of Leclaire and Defournaux.

The material successes achieved by the house during the last ten years have been little short of marvellous. The sum paid each year in wages has increased during that period from £16,257 to £34,715; the sum annually paid in labour-dividends out of profits has risen during the same period from £2,331 to £6,400. In other words, the yearly payments in wages are now double, and the workmen's ready-money receipts out of profits nearly treble, what they were ten years ago. Each individual participant received, at the distribution made last summer, more than 18 per cent. on his year's wages.

Independently of these annual immediate advantages, the Mutual Aid Society assures to each of its members, besides all the benefits of an ordinary Friendly Society, a life-pension of £40 per annum from his fiftieth year of age and twentieth year of work in the house, half of which is continued to his widow for her life. It further pays over an additional £40 in cash at his death to his survivors, and, if he is disabled or killed while on actual duty, pensions him off with the full life annuity of £40, or his widow with a half-pension of £20, and that however short may have been his period of service in the house. The purely economic results of participation in the Maison Leclaire may be summed up by saying that the total of payments out of profits to the participating workmen, since 1842, whether made in ready money or to the account of the Mutual Aid Society, has now reached the sum of £94,700.

I wish the time at my command permitted me to describe, even in the briefest terms, the high educational and moral benefits flowing from the administrative and social institutions which Leclaire grouped around the central principle of his Foundation. I abstain, however, with the less reluctance, inasmuch as a somewhat full account of these institutions is to be found in the *Nineteenth Century* for September, 1880.

The principle of participation, organized under a

great variety of different forms adapted to differing industrial conditions, has been applied with success to almost every class of undertaking, productive, distributive, or purely administrative. In order to give an idea how large is the extent of ground covered by these applications, I will refer, very summarily, to a few leading categories.

In agriculture, undertakings on a participatory basis are being successfully carried on by Herr Von Thünen in Mecklenburg, by Herr Neumann in East Prussia, and by Baron Zytphen-Adeler in the Danish island, Zealand.

In production on a considerable scale, I may cite the paper-mills of M. Laroche-Joubert, at Angoulême, which employ 1,500 workmen; the Maison Leclaire, with its 1,000 or 1,100 painters and decorators; and the cotton-mills of Steinheil et Compagnie, at Rothau, in Alsace, which give employment to some 600 men.

Of productive establishments working on a smaller scale, a conspicuously successful example is the firm Billon et Isaac, at Geneva, which manufactures parts of the mechanism of musical-boxes, and employs about 100 workmen.

Under distribution, a leading house is the *Magazin "au bon marché"* at Paris, property of Madame Veuve Boucicaut, a huge establishment for the sale of manufactured articles of all kinds, which allots a share in profits to about 300 out of the 1,600 persons whom it employs. There are, especially in Paris, very many smaller participating establishments, in different branches of distribution, which it is needless to refer to by name here. In order, however, not to pass over the purely administrative undertakings, I may instance the bank of Vernes et Compagnie at Paris, and a whole group of insurance companies in the French metropolis, including, beside the *Compagnie d'Assurances Générales* already referred to at some length in this paper, *l'Urbaine*, *l'Aigle* et *le Soleil*, *la France*, *la Nationale*, and *l'Union*.

The whole number of establishment now at work on the Continent upon a participatory basis, does not admit of exact determination, but is certainly not less than one hundred.

I have as yet mentioned cases of successful participation only, and an earlier reference may have been expected to the abortive attempts which have occurred on the Continent side by side with the prosperous experiments described above. In particular, I may be fairly asked to explain why I have said nothing about conspicuous English experiments, which have ended in the abandonment of the system. Now, assuredly, it has been from no desire to blink discussion of the English cases that I have abstained from entering upon them here. On the contrary, I think that instances of failure are often precisely those which best deserve and reward a searching discussion.

In order, however, that such a discussion may take place to any good purpose, it is an obviously essential preliminary that the facts on which the failure turned be publicly accessible, in detailed statements of recognised authenticity. In regard to the unsuccessful English experiments, this condition has not been satisfied. The circumstances which brought about the abandonment of the attempt have formed the subject of no detailed and authoritative public statement. As far, indeed, as concerns one of the most important and

best known unsuccessful English experiment that made from 1865 to 1874 in the colliery Messrs. Briggs, at Whitwood, I have reason to believe that a statement as to the causes of failure is likely before long to be forthcoming under the authority of Mr. Henry Currey. At present, however, the basis for a discussion of the abandoned English attempt is non-existent. With regard to the common break-downs, we are, thanks to Böhm-Bawerk's search, in a better position for forming a judgment. Lack of time alone prevents my entering into these cases, in respect to many of which failure can be decisively traced to causes extraneous to the principle of participation.

I have now, far more fragmentarily, indicated what I could have wished, described the main features of participation as practised on the Continent, and remains to say a few words on the system and on its applicability to English circumstances. The theory on which it is based—a theory abundantly verified by experience—is that, by directing the interests of the workmen in the fruits of enterprise better and more economical labour will be obtained, and thus a source of additional profits created. These surplus profits might, indeed, with justice, be allotted wholly to the workmen, in proportion to the efforts produced them. In practice, however, a share goes to the employer, who, so pleases, may, by investing it in a reserve fund, protect himself against losses in bad years. It is thus clear that participating workmen do not share in the profits in a perfectly real way, share losses as profits with their employers. This is denied by opponents of the system; it is, however, an important fact that the fact should be explicitly stated and made good.

In regard to the final disposal of the workmen's share in profits, it will not have escaped notice that all but diametrically opposed to each other are the two systems of annual cash distribution and of Courcy's method of long-deferred possession. The merits of these rival systems are an eager subject of discussion before the *Société d'Economie Industrielle* at Paris, in April last.\* A question on which such authorities as M. Fougère and M. Courcy are not agreed, and which a major part of the houses has rather compromised than decided even inexperience free to utter its opinion. I therefore venture to say that the system of immediate cash distribution seems to me also consistent with the economical theory on which participation rests. The workman's share of profits is earned by his own more efficient and, from the moment of its definitive realisation and ascertainment, becomes rightfully his. It therefore, be temporarily withheld from him on one ground only, that, in his own interest, that of the community, he ought to be denied the free disposal of his own earnings.

I cannot believe that, among the most energetic class of workmen, with whom all participatory experiments should, at least at first, be attempted, there is any necessity for such restrictions. The greatest pains should undoubtedly be taken to bring forcibly before them, at the time of the annual division of profits, the extent

\* "Bulletin de la Société Internationale d'Economie Industrielle," Paris, 3, Rue Perrault, 1880. Tome VII., pp. 145-153.

of systematic and persevering investment. final decision ought, I think, to be left to no can probably decide better what is for an interest than other people can settle it on. As far as English workmen are concerned there can be little doubt that the strong of independence which the influence of societies has fostered among them, would the compulsory detention of sums actually extremely unwelcome, even if it did not, as it very possibly might, render such detention practicable.

Participation, successfully practised under what circumstances, confers, as has been seen, signal advantage on both the parties directly concerned in it. To the employer it gives increased security and peace. For the thrifty workman it acts, not by the hand of charity, but as the fruit of his own heartier efforts, an economized which he may employ in making his old and independent, or, better still, transparent at least, to his children. Further, of even higher significance, it brings to the workman an enhanced feeling of respect for himself and his fellows, based on the fact that he has become, in a very real sense, a partner in the house for which they toil.

It would be an oversight if I omitted to point out the advantage which the public too, in its character of consumer, derives from the system.

Participation encourages excellence of work, and combats every form of trade unionism with singularly efficacious vigour. The necessity of the complaints so constantly made of crastinating, scamped, ungenue work under existing industrial arrangements, and the reversion of the benefits to the consumer to be derived from a system under which these evils are considerations of self-interest if on no other ground, sternly discountenanced by the workmen themselves.

Now only to ask, in conclusion, whether there is any valid reason why a system which has been fruitful in good results on the Continent should not be hopefully re-introduced into this country.

In order to answer this question, we must take two preliminary steps; to set out the economic conditions under which a particular success is attainable, and to examine these conditions and see whether they can, or can not, be satisfied in this country.

First, that participation may be advantageously introduced in any particular branch of the workmen must have it in their power, to perform efficacious labour, to increase the quantity, to improve the quality, or diminish the cost price, of the production in that branch. The conditions which these results are attainable—the conditions which manual labour can thus exert upon the system—must necessarily be different in different industries. Much will depend on whether the workmen employed are cheap or costly, and on the part which machinery plays a subordinate or a pre-eminent part in the production. The degree in which the system of labour-superintendence admits of modification, is also an important element of the question.

A promising field is, therefore, manifested by such industries as house-painting, glazing, plumbing, &c., in which the workman plays the predominant part, and

individual superintendence is well-nigh impracticable, and where no one will have the hardihood to assert that the workmanship is already of so zealously active a type that its excellence is unsusceptible of further improvement. Much the same may be said of agriculture. In coal-mining, as I am assured by the most competent witnesses, there occurs a huge waste of materials, due solely to the fact that the colliers have no interest in preventing it. Even in machine-dominated industries, the vigilant attention with which a really zealous operative superintends the instruments under his charge has a surprising influence on the final result. Mr. Kenward, the very able manager of the lighthouse department of Messrs. Chance's glass-works, near Birmingham, where the prevalence of piece-work supplies a direct gauge of the results attained by individual effort, assured me that, in such an apparently routine occupation as superintending a machine punching holes in a metal plate, a thoroughly active workman could realize a surplus wage three times as great as that obtained under identical conditions by a less strenuous, but not less skilful or less capable, colleague. At a meeting in Birmingham, attended by representative artisans, it was asserted without contradiction, by an exceptionally well-informed man, that "an enormous preventable waste occurred in every trade in the town."

It would appear, from the above considerations, that there is no lack of scope for participatory successes in many branches of English industry. The question may, however, be raised—Can our workmen be brought to recognize the benefits of participation, and put forth the sustained and intelligent efforts which can alone ensure the successful working of that system?

On this issue the rapid spread among the working class of education, and of the feeling of mutual confidence which all genuine education fosters, may well relieve us of serious hesitation. No one who has marked the eager interest which men of that class now take in social questions; or who, like myself, has seen hundreds of colliers in regular attendance at a course of systematic lectures on Political Economy, delivered week by week for three months on end, by a popular, but none the less thoroughgoing, exponent of that subject,\* can entertain a doubt that participation in profits, if once clearly set before the working classes of this country, will soon be thoroughly understood and appreciated by them. My own very decided conviction is, that participation has a great future before it in this country; and I am strongly confirmed in that view by the opinion of the leading French exponent of the system. Writing to me on Nov. 8, 1880, M. Charles Robert expressed himself in words which I translate as follows:—

"Wherever there exist in combination industrial

\* Mr. W. M. Moorsom, of Trinity College, Cambridge, delivered, in the autumn of 1880, a course of 12 weekly lectures on Political Economy, to audiences consisting chiefly of pitmen, at five centres in the Newcastle coal district. The lectures were organized under the University of Durham extension scheme; and at one exclusively mining centre alone, 400 tickets for the entire course were sold in advance. "No public speaker," writes Mr. Pringle, of Barrington Colliery, Northumberland, "ever took away from our remote county so large a share of good wishes and heartfelt gratitude, nor left behind him such a popular name as Mr. Moorsom."—See *The Common Good*, Jan. 15, 1881, p. 239. Published at 292, Strand, London.]

energy, intelligence, and the spirit of initiative, the final success of generously-conceived innovations is almost always assured. And where is a greater and better success to be looked for than in England, the country of personal independence, and of combined effort, the classic land of free and fruitful activity, whose denizens are accustomed to mass their individual powers, and to serve as models to every student of the theory and practice of association? The admirable results obtained on your side of the Channel by Co-operative Societies of Distribution, the magnificent development of your Friendly Societies, the formidable power of your Trades' Unions, prove to demonstration that England will well know how to make participation in profits prosper within her borders. English advocates of that system will assuredly obtain a favourable hearing, as well from industrial chiefs as from workmen, and I make bold to hope that we in France shall soon be called upon to register their successes, and profit by their examples."

Before sitting down, I desire to make a practical suggestion to which I attach considerable importance. It is manifest that before participation can be extensively tried in this country with good prospects of success, the results attained on the Continent must first have been adequately studied both by English employers and by English workmen. Now, what are the means as yet provided for pursuing this study? In the spring of 1879, a society composed of employers engaged in industry or commerce was established at Paris, having for its sole object to facilitate the practical study of participation in profits. This society has already published in its periodical *Bulletin* the regulations of the most important participating houses, and has assembled in its library a mass of unpublished rules in force in the less conspicuous establishments. It is now bringing out in a French translation, with the author's latest additions, the work of Böhmert, which is a real mine of trustworthy information, particularly as to results obtained in Germany. Clearly, therefore, an inquirer who wishes to make a practical study of the subject may derive the greatest assistance from the French society. He finds abundant matter in its publications, and, should he desire further information on points of detail, has only to place himself in communication, through its officers, with the heads of houses abroad whose systems he may desire to investigate. But these facilities are as yet restricted to students possessing a good knowledge of French, and a not inconsiderable stock of leisure. In order that they may be effectively thrown open to all classes in this country, means must be taken for publishing, in plain readable English, and at a low price, the most essential facts which have been ascertained by continental research. The work might well be undertaken by a special society, which should endeavour to facilitate in England the practical study of participation, whose objects and whose title should, in fact, be identical with those of the French society. Such an association would disseminate trustworthy printed information, promote the reading of papers, the delivery of lectures, the holding of discussions, and generally seek, by every available means, to spread sound knowledge on the subject with which its operations were concerned. It would also serve as a bond of union and mutual support between such English houses as gave an actual trial to participation, and between all persons interested in

the progress and development of that principle, a very important feature of its work would be the maintenance of close and cordial relations with the French society, and with the movement in other parts of the Continent.

In order roughly to gauge the amount of support likely to be forthcoming for a scheme of this kind, I should be very pleased to receive, at a College, Cambridge, the names and addresses of any persons, whether occupied or not in industry or commercial pursuits, who, were such a society to be called into existence, would be disposed to join it.

## DISCUSSION.

Mr. Wolstencroft felt sure that the scheme applied with success to many industries, but others, piece-work would be superior. He gave instances where double the amount of work was done with the same number of hands on piece-work much less expense to the employer. He did not think the system of participation would be applicable to collieries. There the workings were let out to a man, who was paid so much a ton for all which came out of the drift. He was not paid dirt, but only for the amount of coal raised. A higher price for that raised in good conditions. In Oldham the co-operative system was commenced. It was found to answer very well, one mill dividend of 25 per cent.; but, in consequence, there was a rush of capital into this industry, and mills were built at one time, some containing a quarter of a million spindles, and then they became glutted. Participation might readily be applied to warehouses where the work could not be done on the piece-work footing; but generally he thought it was best to pay men by results.

Mr. Lloyd Jones suggested that it would not be wise to discuss the disputed question of piece-work. Before dealing with the question, he wished to correct the Chairman's statement that the trades unionists of the country were opposed to proposals for a participation of labour and profits. He was not aware that such was the case, and perhaps as large an experience of trade unionism as any man in the country. He knew all the leading branches of industry where trade unionism existed, and he did not know a single case of personal hostility to such a scheme. He knew that Mr. Briggs succeeded with it, and no doubt that gentlemen had many grievances, which he would make known if he published his statement; but there was quite another side to the question, which it would be time to deal with when Mr. Briggs had published his statement. Nothing could be more interesting than such a subject as that now brought forward for no other reason than that it was impossible that the present industrial system in this country could go on. He joined trades unions years ago, and had been in intimate communication with members of various trades unions from that day to this, and he was more satisfied than ever that the piece-work business was now conducted would break down unless interests which were antagonistic could be reconciled. The partnership spoken of was where you got a man of large intelligence and benevolence, who undertook to do the work in which he called his workmen to assist him, and where the workmen were absolutely satisfied as to the intentions of the man who called on them to co-operate with him. There was nothing more certain than that the suspicion of the employer by the employed on the whole thing would break down. He did not

the reader of the paper where he spoke of the break down of the attempts at co-operative production in this country.

Mr. Taylor said he did not speak on co-operative production. His remarks were exclusively limited to industrial partnership.

Mr. Jones said he had alluded to Mr. Briggs' scheme, which consisted simply of a bonus given by the vote of the shareholders at their half-yearly meetings, the workpeople being entirely at the control of the shareholders. The shareholders voted according to what they thought it ought to give, and the workpeople found themselves suddenly cut off until their bonus entirely disappeared. He went further, that the workpeople felt all along that a portion of the design of that experiment was to draw away from the trades unions to which they belonged. Now, there were a number of gentlemen who were engaged in the work of distributive production, and the workmen connected with that had in their hands what they called the organisation of the country. The business they were doing was, perhaps, £14,000,000 or £15,000,000 a year. They had, therefore, in their hands the orders from all people going to these various stores, and, having those in their hands, they could regulate production precisely as it was their purpose. Instead of manufacturing speculation, as most manufacturing was carried out, and at very serious loss occasionally, they manufactured accordance to the custom which they had organised. Thus the demand came before the supply, and the fatal point in the present system, where it overrid the supply of any given article, and so reduced its market value, and ruined profits, which had been the case in the coal industry, was avoided, in this way they produced a scientific relationship between the supply and the demand. The co-operators established a place, not referred to in the paper, at Leicester, called the Leicester Boot and Shoe Works. Sometimes they did not make heavy profits, because they had to compete with the outside market, when there was no absolute necessity to do so. Here there was no speculation, and no fear of loss which they did not bring upon themselves, and the demand and supply was brought into a kind of harmony, which had ended the bankruptcy and ruin so common in trade. He believed that if employers would put themselves into friendly relationships with their employees, they would hit upon some plan of running side by side without injuring each other, and bring out of the country the fair wages for one, and fair for the other.

Mr. Stiller said it ought not to require many words to say anyone of the advantages of the participation hour. It was proverbial that carelessness was ruin. He used the word in no offensive sense, simply as the absence of care. Anything which identifies the interests of the labourer with his employer was certain to result in good. If, therefore, it was very good to allow labourers a little participation in profits, it would be better to allow them to have the best of all, if such a thing could be arranged, their interest in it should be entire. The chief difficulty that appeared to crop up, was that there were three kinds of labour; constructive labour, active labour, and distributive labour, and it was a very difficult thing indeed to say what portion of the profits of distributive labour should fall to the labourer. The result of labour, until it was measured, was an unknown quantity, and in that case, if a quantity, it was quite right that the labourer should participate, and have an equal share of it as a remuneration for his contribution to bring it about. Unfortunately, the labourer could not wait for the result; he generally lived from hand to mouth, and, therefore, he sold his day's labour at the market rate, and the market rate was the estimate which somebody

else formed of what the result was likely to be. Wherever the result was likely to be very prosperous, a man would willingly pay double for the labour. If therefore, the reader of the paper, instead of saying the labourer was to share in the profits of industry, said he should share in the results of the industry, it would present the question in a very different aspect. There were very few labourers indeed who were prepared to stake their daily bread on the results of their industry. In fact, in these days, we had too many instances where combined industry was most disastrous. If the wages were not equitable, the man ought to get more; but the capitalist would only pay the market rate, which fluctuated like the market rate of anything else. In England, we had instances of that sort of co-operation on a large scale. One instance was the old East India Company, where, originally, the dividends of the shareholders were limited to 10 per cent., and, consequently, they had no other field for disposing of their surplus profits than in raising the wages of their employees. These were raised to such a grand sum that they commanded the very finest industry and talent of Great Britain. The system, as carried on at the India-house, closely resembled that described in France. Part was paid in the shape of wages, and part in the shape of bonus or retiring allowances. It would be a grand thing for every labourer if he were entitled to a retiring pension at a certain age; but very few would like to trust their employers with such an amount for 30 years; and he certainly should prefer to get it in cash, and to put it in some insurance office, in which he had more confidence.

Mr. Ganney agreed with Mr. Lloyd Jones that the industrial system of the country must be changed. As one of the Society of Arts reporters at the Paris Exhibition, he had some opportunities of observing from different standpoints the position of labour on the Continent as compared with England; and he had spent some years in America. He had noticed there that employers would cheerfully pay dollars a day and succeed, where an English employer would scarcely pay shillings and fail. The fault lay very much in this, that there were not sufficient competent employers; the men who directed the large industries of the country in many cases not being practically acquainted with the business they carried on. In old days, the men who built up the trade of England were actual workers, but now he knew a series of trades which were being positively annihilated by foreign competition, for instance, the English clock and watch trade, in which men now made money by putting the London trade-mark on foreign articles. That was a state of matters for which he long worked to find a remedy, and he trusted that the direction in which the reader of the paper was working, viz., the practical co-operation of the workmen with competent employers, would lead to a solution of the difficulty. He had made attempts to introduce the co-operative system, both in London and in Coventry, but in neither case had they been successful, on account of the inability of the workmen to find sufficient capital when trade was in full swing. If they could only get large capitalists to induce practical workmen to take an interest in their business, many trades which were now languishing on account of the antagonism between the capitalist and labouring classes, would revive, and increase to an extent which few could conceive.

Mr. Chapman regretted that the reader of the paper had not called attention to the speech of the Emperor of Germany, which appeared in that day's papers, in which he alluded to the scheme brought forward by Prince Bismarck for improving the condition of the proletariat. That scheme, as published in the *Spectator* for January 5th, consisted in making assurance against accidents compulsory in some branches of labour, half the premium to be paid by the employer, and where the

wages were below a certain amount, two-thirds of the remainder to come out of the poor-rate. The fund thus raised would provide sick allowance up to two-thirds of the wages, with a provision for the widow and children. It was also intended, he understood, to carry the scheme still further. The failure of Messrs. Briggs' experiment had been referred to, but what was the cause of the failure? The profit, the second year of the experiment, was £30,000, but when the price of coal was considerably raised, and the profits grew to £60,000, they did not like dividing it amongst their workpeople, and that was the cause of the failure. There were many examples of the success of this system in England, and he was sorry he had not the materials with him to quote them.

Mr. H. Solly desired to express his most earnest sympathy with the movement, which was evidently growing, for promoting this participation in profits, and did not think they need be at all discouraged by the failure of one or two attempts in this direction some years ago. One had just been referred to by Mr. Chapman, and they knew how many failures the co-operative movement suffered before it attained its present success. It had almost entirely died out before the Rochdale Pioneers began their wonderfully successful enterprise. There was hardly any social, industrial, or political movement which had not to encounter failure at the outset; and it was only in that way that experience was gained which led to ultimate success. Mr. Chapman, however, was in error as to the cause of the failure of Messrs. Briggs' experiment. He knew Mr. Currer Briggs very well; and he was one of the last employers who would grudge his workmen a share in the profits of the business. If he had been ever so grudging, he would be the last man to be so when he saw beneficial results accruing to the firm from the participation. The real cause of the failure was the relation, or supposed relation, of the firm and the *employees* to the trades union. He would not go into that, but he did not consider the men were to blame at all in the matter. Mr. Briggs himself deeply regretted the cause, and probably if it had rested with him the difficulty would have been got over. The same with Fox, Head, and Co., of Middlesbrough. Jeremiah Head threw his whole heart and soul into the matter, and as far as the profits went, it worked well. As regards the beneficial results of this system, he had recently been informed that the manager of the stationery department in one of the largest firms in the metropolis had saved his employers nearly £800 a year through the introduction of the system. This was simply because he felt it to his interest to make every effort to prevent waste. When he mentioned this fact on a former occasion, an employer said that the man must have been shamefully neglecting his duty not to have made this saving previously; but even granted that it were so, you must deal with facts as you find them. If you found a certain system would induce men to be more careful, and increase the profits of their employers, and another would not, it was only common sense to use the one system and not the other. This had been proved to be the case, for where this system was carried out, the saving was immense. One objection often brought against it was, that while the workmen were willing enough to share the profits in a good year, they would not like to share the lesser in a bad year. His answer was this, which might not be correct, but he had always felt it to be sufficient, that the bonus should be calculated, making allowance for the losses of bad years. He did not imagine there would be any difficulty in making a calculation of that character. He entirely endorsed the remarks which had been made, that some change in our industrial system was inevitable. The trade of this country was undoubtedly in a very serious condition; every now and then the reports from consuls abroad stated that in this and that particular trade we were being superseded, sometimes

by continental firms, but chiefly by America was informed by a relative of his, who was in New York, that a mining engineer in England him that his men always preferred American in illustration of that they found intelligent men had worked in America, telling them that the more co-operation between employers and workmen there than in this country. He need not go into the causes of that, but the effect was undoubted. It was carried out in consequence in a way in which could be where the employer and workmen were on friendly terms. Then, again, the question of the laws came in, but that was beside the present point. He was thoroughly convinced that, although the system acted chiefly upon the pocket, it was of large extent, a moral question as well; and it appeared to him that the lesson to be drawn from Leclaire's life and character was of incalculable importance. He was thankful to know that his own was being held up, not only by Mr. Taylor, Chairman, but by a lady friend of his now present, Hart, who had brought it before workmen's eyes; they could succeed in introducing a more friendly spirit into the relation of employers and workmen, get masters and men to have that true sympathy one another which must lie at the foundation of success, this bonus system would come in and flourish. It never would be broken down, if there was the same brotherly spirit as prevailed in Leclaire's management.

Mr. Nuttall understood Mr. Taylor to say that under this system, new profits might be created which were now lost; he did not ask that the workmen be given anything which the employer now had, but that the workmen should be induced to create new profits, and have a share of it. If that was what he meant, he did not see how any man could object, but he would be glad to see the workmen to produce more and waste less, and on more friendly terms with him than hitherto. They probably live to see this system take root in this country, but it had not done so yet, for which, many would doubt could be given. The principal reason was, because the tendency of the age was towards capital per head was likely to be employed in less than in previous years. In the cotton trade the employer £200 per man, and in the engineering trade about the same. Now, it took a man a good many years to save that capital. A shoemaker worked for himself in the old way, he could carry his kit with him round the country, and it was easy for him to work on his own account, and make profits for himself, or to join with others, but so now. There were large workshops in that in every other, and the amount of capital per man was much greater than formerly. This must be the tendency in all trade machinery would have to do the work which manual labour had hitherto done; that would be more difficult in the future for the workmen themselves to become the owners of the work they were employed; and he felt very strongly that whatever they might desire, the end would be that the public themselves would ultimately employ the capital, employ the workpeople, and share the profits. He did not agree with many of their friends who thought the workmen would ultimately become the owners of their own works; nor did he even think it desirable that that should be so, because the tendency of the workman was the same as the tendency of the employer; he would make all he possibly could for the customer. He would sell his shoes or his goods as dear as he could, and think he was doing right. He was a capitalist did now; and not only that, but he would pay the least possible wages. The workmen where he was not actually employing others, but had to employ others, would pay the low

had seen this actually done times out of measure. He had seen the workmen in Oldham—where they were shareholders in joint-stock companies—in one mill where they were employed, that was not only right, but that it would pay the workmen an interest in their work; and he saw the same workmen as shareholders holding £5 invested in the concern, urge that it was not that it would not pay, to give other workmen the profits. These were practical difficulties. In years to come they would see a consideration, but not in the direction that some of the well-wishers really desired. He had dealt with cotton buyers, and fail, because a bonus of £1 a week extra to him, was in the receipt of £7, £8, or £10 a week, had no influence—it was too small. £5 a week extra, and he would neglect his material at Liverpool, and, perhaps, save one-sixteenth of a penny per lb. in buying; but the yarn in Manchester would take the same. But he had seen other workmen begrudge an extra £5 or £10 to men who had acted in this way; they might have saved hundreds of pounds. The middle-class and high-class employers, did not do that; and they, as working men, learn to be more liberal in such matters. Nothing would succeed anywhere, it ought to be in Oldham, for there every cotton-mill had risen from a workman. He knew when he was a workman, he could produce better than he did or did not waste his master's material; and every workman knew that he was a workman; every trades unionist knew it, and every man knew it. The point was how to get it and invest it. In Oldham, there were men, who owned £4,000,000 of capital, all in the cotton, iron, coal, or paper trades; they ought to give their own work-interest in their works, which would be a larger profit divisible among them as shareholders; yet they did not do so, and it was said that they were friendly to the plan. The plan had been tried in many places, four or five cotton mills—with the cotton, the seller of yarn, the engineer, and others, and they had tried it in various places. In an Oldham engineering works, the manager was director for many years, and knew it, every workman was actually made a shareholder to induce him to take an interest in the work and save material, but what was the result? Those who were dissatisfied with the plan, combined with others in the workshop or factory to get more. If they could not get it from the manager, they then tried to get it from the shareholders. If they could not succeed in that, they tried to get it from the manager, and when they could not get it from him, they tried to remove the manager. They could not remove him, they tried to remove the directors, and the result was they had to be dismissed. Everybody must regret to see that the workmen themselves, but it was doing these facts. What was wanted, was that the bulk of the workmen to see that it was to their interest to save instead of waste, and that there was more pleasure in working than in idling time away during working hours. They could not see how any working man could be idle in idling time away, either his own or his employer's, but they had got into that habit, and he saw his way yet to any practical scheme to induce the workmen to become more economical with their time, tools and materials. He had tried this in a colliery. He and a few friends in a colliery and tried to make it succeed. They gave the workmen an interest in proportion to what

they did, and it succeeded with them, but when they went down into the pit and tried to induce the cutters themselves to use less powder, to be more careful about mixing dirt with the coal, and to keep the water away from the mine, and so on, it was impossible to induce the colliers to take any interest whatever in the master's affairs. He offered them an extra sum per ton, but still they could not do it. He thought there was always a fear in the mind of the workmen that there was something else in view when anything was offered them, and the way in which they had been treated necessarily caused them to have those feelings. It would take many years before workmen would feel, as Mr. Jones put it, that they were really trusting somebody deserving of being trusted. He could not tell the meeting one half of what he should like them to understand on this subject, but he thought there were many forms of industrial partnership and co-operation which would succeed side by side with each other. It had succeeded in the works of Messrs. Platt Brothers, of Oldham, the largest engineering works in the world. There there were 20 or 30 men, to whom they paid £1,000 to £1,500 per annum each, with a bonus in addition, but they did not allow the bonus to be withdrawn. It was accumulated with the profits on it, year after year, and when they had been in the firm a certain number of years, they were entitled to sell out. He had many companions, half-a-dozen of whom were in receipt of £500, £600, or £800 per annum, with a bonus, who had been their principal foremen for years, and who did study their employers' interest and their own. But the bulk of the workmen had no interest in the concern; only the heads of departments. It succeeded at Accrington, in the machine works there, and in many other places where heads of departments only were taken into account. He should have been glad if Mr. Taylor had told them where it succeeded, what proportion of capital per head was employed, and he should imagine that in the house painters, watch-makers, and many of those industries, the capital was very small indeed, and that there it would succeed better than in large concerns.

Mr. Benjamin Jones said the last speaker had gone into a great number of details to show why the participation of labour in profits should succeed, and then why it should not. Some years ago he was as thorough an advocate of labour having a share of profits as could be found anywhere; probably, he was only an instance of a sort of ebb and flow of opinion which had taken place amongst working men generally. Some years ago, the feeling amongst hundreds and thousands of workmen was that this participation was a good thing; but a great proportion of them, who had been working hardest and thinking most, got rather rich, and then changed their minds, because they got into the position of capitalists. There were concerns where they gave labour a share; but when they found they were getting rich, they thought they could do without the labourers' co-operation, and stopped his profits. Then bad times came, and profits dwindled away, and many believed it was on account of what he considered the unjust treatment of the labourer; and some of those who, in the high tide of prosperity, were against a division of profits, were again changing their minds, and coming to believe that it was the right thing after all. No one had mentioned Mr. Taylor's suggestion to have an association to discuss this question, but the discussion which had already taken place showed how useful it would be; and he thought they could not do better than form such an association, where details could be gone into. It seemed to him an incontestable fact, that to give a man an interest in the profits must have an influence on his industry. Take his own case; he was in service, in a position, where he thoroughly enjoyed the work he had to do, and he would not exchange it on any account.

It might be said that, with such a position, no inducement offered him would make him more zealous, but still he must say that when he had made what he considered a good hit for his employers, it rankled very much in his mind that it did not add a *6d.* to his wages. He considered it was essentially unfair that capital should take all profits which resulted from enterprise and integrity of industrious labourers. As the working classes of this country increased in intelligence, they would make up their minds that they would have a greater share in the produce of their industry, and the question for capitalists would be, would they have a grand battle between their *employers* and themselves, or try to devise some such means as Mr. Taylor had suggested, for uniting their interests, and sharing their profits with them. If the question was left to the workmen, they would devise means by which the capitalists should only be allowed 3 or 4 per cent. on his capital. Personally, he should prefer such a solution, but it would take a long while, and he doubted whether it would be applicable to all industries; and, in the meantime, he welcomed the suggestion now made as likely to bring the two great classes into more amity with one another.

Mr. Trowby said the question had been asked, why this principle succeeded in France, and not in England; but he thought the instincts of the two nations were very different. A Frenchman was content to live in part of a house, while an Englishman wanted a house to himself. Then there was a vast difference in emoluments for the same kind of work, as in the case of the clergy, where one man received £1,000 a-year for less work than another received £100 a-year for, and yet they were not willing to set that right. The same kind of thing applied in all industrial occupations. There was a kind of aristocracy in manufacture and distribution. Mind naturally took precedence of the actual labour, and it became the function of the mind to draw around it other minds. No nation had done so much towards increasing the distribution of products as England, and it had been done by simply making the labourer a partner to the employer. In the large distributing firms, down to a certain grade, each man received an emolument according to the profits of the concern. In the large wholesale firms, the buyers were paid according to the amount of the turnover, and under them were salesmen, who were also paid according to their ability. In the case of the large painting and decorating establishment in Paris which had been referred to, he did not suppose there was a large amount of capital employed; but how would the principle work if it were applied to all concerns of the same kind? There was no outlet for a man's ability, if he wanted to start for himself, he had to face the fact that he would lose whatever he had deposited in the concern. In this country a man could work his way up to the top of the tree, and then strike out for himself. The lowest class of labour was always regulated by the demand for increased pay.

Mr. Mincard said he had looked at this question from three different standpoints—as a workman, as a foreman, and as an employer, and he had felt, from the time when he knew how to use his tools, that he ought to have an interest in the work he had in hand. The only interest he could then show was to do his work in the best manner he could, and the result was that he almost always remained with his employers as long as it suited him to stay. When he was a foreman, he made a similar suggestion to that brought forward by Mr. Taylor. He was once carrying out a large job in the country as building foreman, and he suggested to his employer that he should have 10 per cent. on the profits of it, he, on the other hand, offering to deposit 10 per cent. as his share in case of a possible loss. That offer, however, was refused. He was now an employer, being what was called a speculative builder; and, although in

good times a builder could make fair profits, in the same neighbourhood, and in the same class of property, he might lose twice as he had an opportunity of earning in good years the last two years he had been, at one time and there were then men in his employ offered to let him have every pound. He believed this vexed question of capital could only be solved in the mode suggested by Taylor; but it seemed only fair that those the profit should also share the loss. He was willing to join such an association as had been formed, for the purpose of enlightening themselves, for it could only be done by first them. He had men in his employ whose wages were often raised, and he never let a holiday go giving those in a leading position a bonus when waste was done in large metropolitan firms to the extent that he had actually thrown up his hands. On the other hand, you might drive men by making them do a lot of work which was worth nothing. He found piecework answer in the simplest operation as excavation, and then he never attempted to pay a man's wages because he earned a good deal.

Mr. George Shipton moved the adjournment of the discussion, which was seconded by Mr. Nutt.

[The adjourned meeting will be held February 26th.]

## CORRESPONDENCE.

### "SUGGESTIONS FOR PREVENTING SMOKE."

As it would appear that the statements in my letter of the 29th ultimo, have not been understood by Mr. W. D. Scott-Moncrieff, I venture, in as few words as possible, to make clear to him.

In Mr. Moncrieff's scheme, it is proposed coal intended for fuel through gas retorts instead of taking 10,000 cubic feet of gas per ton of coal, to take 3,333 cubic feet, and to reduce the quantity through the retorts, in proportion that may be found most convenient result of doing so (he says) is startling; "as he states that the coke or smokeless fuel from retorts would give out 20 per cent. more heat than coal, and would therefore be found of great value for heating the retorts, while the surplus gas not required in the manufacture of gas, could be used for domestic purposes, thus rendering London a less smoky city."

Now, if the before-mentioned is the scheme Mr. Moncrieff advocates, then I must repeat that it has never even been tried—adopted—at the Woolwich Arsenal Gas Works.

In Mr. Moncrieff's letter which appears in the *Journal* of the 11th inst., he remarks that of the 29th ultimo, I confirm the statements in every detail and particular. Now several remarks in the order in which they appear, we shall see how far his statements are by facts.

Mr. Moncrieff alleges that when in the management of the gas works at Woolwich, he used a "short extraction." This is entirely untrue in every case he allows the coal—whether coal or cannel—to remain in the retorts as long as is necessary for extracting all the gas from one-third only, as recommended in Mr. Moncrieff's scheme, and the length of time necessary for this depends entirely upon the character of

on gas coal, about six hours, and for canal, 12 hours.

Moncrieff then alleges that the fuel resulting from short extraction is superior, and that I contended, "that the coal used was volatile and that on a long extraction it contained very bad properties, and was not used under the

Now, my letter of the 29th ultimo contains a statement, but the very opposite, for I most pointed out that it was the coke from the worked during a four-hour (or short time) and with a volatile canal coal, which conveyed little heating properties, and consequently used as fuel under the retorts. The words in Mr. Moncrieff's, not mine, and they do not where in my previous letter.

Moncrieff then asks, do I mean to say that the coke under a short extraction than under a Not having tried his scheme of "short," I am unable to answer this question. It is, that the coke resulting from the six-gas, for which we always employ common gas by "Pelaw," is of good quality, and possesses heating properties, and makes a very good fuel, but resulting from the four-hour charges, for invariably use a canal coal, is simply as a fuel.

Moncrieff then asks, do I mean to deny that the coke comes off during the first two or three hours, less than it comes off most rapidly during 12? I am not aware that I have made or de-statement in regard to either of the above and, as I am only concerned at present with matters made by Mr. Moncrieff in regard to the Royal Gas Works, I do not think it necessary to be subject under discussion. At the same time to his last question, I do most distinctly having adopted the scheme which he advocates paper, even to meet a few exceptional cases. My endeavour has always been to get, as much gas as possible out of the coal, and as to none in the coke, whereas, in Mr. Moncrieff's, he advocates taking only a little out of about 3,000 cubic feet per ton) and leaving a portion—between six and seven thousand—in the coke.

though I shall be pleased to adopt any plan as practically tried and proved, and which will enable me to manufacture a better and cheaper gas, at the present, and until Mr. Moncrieff has better and more reliable to put before us, to sufficient intelligence" to deter me from to convert good profitable gas works into coke for partly carbonizing coal and manu-facture gaseous coke or smokeless fuel, of such value, that in the condition in which it would the retorts, the mere handling and exposure for a short time would, I believe, convert it up of "brease" or rubbish.

Moncrieff states, in conclusion, that he was un-satisfactory official relations between Mr. Wallace and I, further, that he is not, even now, aware of relations are. I can scarcely imagine this to after his reading my letter of the 29th ultimo, and seeing that there are so many taining the information had he wished for it, but I have been connected with the public the past 30 years. I can only attribute Mr. Moncrieff's continued ignorance to the fact that as he has little trouble to inform himself on this did to investigate and ascertain the true state before making the incorrect and random which appear in his paper.

and, Woolwich, Feb. 14. J. A. C. HAY.

name has been most freely used by Mr. in the paper he recently read before the

Society of Arts, I beg to say that the statements made by him referring to the Royal Arsenal Gas Works are wholly incorrect, and were not given to him by me. Neither do I know anything of Mr. Moncrieff, further than that the first time I ever saw him was less than a month ago, when I met him looking over the works here as an ordinary visitor. JOHN WALLACE.

Royal Arsenal Gas Works, Woolwich.

[In order to prevent further correspondence, the letters from Mr. Hay and Mr. Wallace were sent, in proof, to Mr. Scott-Moncrieff, with a request that he would reply to them, if he wished to do so. His answer is given below. A few sentences have been omitted, which refer, principally, to personal matters, rather than to matters of fact. This correspondence will now be closed.—Ed. S. of A. J.]

I have the proofs you have sent me of letters from Mr. Hay and Mr. Wallace. The former gentleman, I find, is not known among gas-managers as an expert; it is to be presumed, therefore, and he seems to admit, that he obtained the information which forms the basis of his letters from Mr. Wallace. Your readers may judge of the disadvantage I am at in this correspondence, when I inform them that so far from Mr. Wallace having "seen me for the first time less than a month ago," and "having met me looking over the works as an ordinary visitor," he was specially introduced to me last autumn by an engineer of the highest eminence, belonging to the Gun Factory, and a personal friend of my own. On that occasion, Mr. Wallace took me to what he called his "thinking-box," and we went into the figures of my proposed scheme, which he did with expressions of the greatest interest. It was then, and on other occasions since, that he told me of his experience with regard to short extractions. It is to this information, and this alone, I referred. To make a general practice of a short extraction at Woolwich Arsenal, where the fuel used for heating is out of all proportion to the quantity used for light, is what no man in his senses would think of. This, however, has no connection with what Mr. Wallace did or did not tell me about the short extractions. In Mr. Hay's last letter, he suggests that nothing but the every day practice of gas-making had been resorted to at the Arsenal. In his previous letter he speaks of exceptional practices. I cannot reconcile these discrepancies, nor do I care to make the attempt. W. D. SCOTT-MONCRIEFF.

Feb. 17.

## MEETINGS OF THE SOCIETY.

### ADJOURNED MEETING.

Friday evening, at eight o'clock:—

FEBRUARY 25.—Discussion on Mr. Sedley Taylor's paper on "The Participation of Labour in the Profits of Enterprise." W. H. HALL will preside.

### ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

FEBRUARY 23.—"River Conservancy." By CHARLES NEVE CROSSWELL. The Hon. CHARLES WESTWORTH FITZWILLIAM, M.P., F.R.G.S., will preside.

MARCH 2.—"Lighthouse Characteristics." By Sir WILLIAM THOMSON, LL.D., F.R.S. F. J. BRANWELL, F.R.S., Chairman of Council, will preside.

MARCH 9.—"Ascents of Chimborazo and Cotopaxi, in 1880." By EDWARD WYTHAM.

MARCH 16.—"Buying and Selling; its Nature and its Tools." By Prof. BENJAMIN PRICE, M.A. Lord ALFRED S. CHURCHILL will preside.

MARCH 23.—"The Increasing Number of Deaths from Explosions, with an Examination of the Causes." By CORNELIUS WALFORD.

MARCH 30.—“Recent Advances in Electric Lighting.” By W. H. PREECE.

APRIL 6.—“The Manufacture of Glass for Decorative Purposes.” By H. J. POWELL (Whitefriars Glass Works).

#### FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

MARCH 1.—“The Languages of South Africa.” By ROBERT N. CUST.

MARCH 15.—“Diamond Fields of South Africa.” By R. W. MURRAY.

APRIL 5.—“Trade Relations between Great Britain and her Dependencies.” By WILLIAM WESTGARTEN.

#### APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

FEBRUARY 24.—“Deep Sea Investigation, and the Apparatus used in it.” By J. Y. BUCHANAN, F.R.S.E., F.O.S. Captain Sir GEORGE S. NARES, R.N., K.C.B., F.R.S., will preside.

MARCH 24.—“The Future Development of Electrical Appliances.” By Prof. JOHN PERRY.

The meeting previously announced for April 7 will be held on May 12.

#### INDIAN SECTION.

Friday evenings, at eight o'clock:—

MARCH 4.—“The Results of British Rule in India.” By J. M. MACLEAN.

MARCH 25.—“The Tenure and Cultivation of Land in India.” By Sir GEORGE CAMPBELL, K.C.S.I., M.P.

MAY 13.—“Burmah.” By General Sir ARTHUR PHAYRE, G.C.M.G., K.C.S.I., C.B.

Members are requested to notice that it may be necessary to make alterations in the dates of the above papers.

#### CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Second Course will be on “Watchmaking,” by EDWARD RIGG, M.A. Three Lectures.

#### Syllabus of the Course.

##### LECTURE III.—FEBRUARY 21.

Necessity of efforts to promote the art in this country—Need of education, theoretical and practical, in horology—Literature—Great want of uniformity in gauges, screws, &c.—Exhibition of ordinary and complicated watches, and of watchmakers' tools—Conclusion.

The Lectures will be illustrated by Specimens, Models, and Diagrams. The different movements, &c., will be shown enlarged on the screen by means of the Aphengiscope and the Electric Light.

The Third Course will be on “The Scientific Principles involved in Electric Lighting,” by Prof. W. G. ADAMS, F.R.S. Four Lectures.

March 7, 14, 21, 28.

The Fourth Course will be on “The Art of Lace-making,” by ALAN S. COLE. Three Lectures.

April 25; May 2, 9.

The Fifth Course will be on “Colour Blindness and its Influence upon Various Industries,” by B. BRUDENELL CARTER, F.R.C.S. Three Lectures.

May 16, 23, 30.

#### ADMISSION TO MEETINGS.

Members have the right of attending all the Society's meetings and lectures. Every Member

can admit *two* friends to the Ordinary Meetings, and *one* friend to the Cantor Books of tickets for the purposes have to the Members, but admission can also on the personal introduction of a Member.

#### MEETINGS FOR THE ENSUING WEEK

MONDAY, FEB. 21ST.—SOCIETY OF ARTS, Adelphi, W.C., 8 p.m. (Cantor Lectures. Rigg, “Watchmaking.” (Lecture III.) Royal Asiatic, 22, Albemarle-street, W., 4 John Cain, “On the Kols or Ghonds of C 2. Mr. Cyril Graham, “Remarks on Laeghian Language of the Caucasus.” Royal United Service Institution, Whitehall Mr. W. H. White, “Pumping Arrangements War Ships.” Institute of Surveyors, 12, Great George-street, 8 p.m. Mr. G. B. Crickmay, “Ecclesiastical.” Medical, 11, Chandos-street, W., 8½ p.m. Victoria Institute, 7, Adelphi-terrace, W. Dr. J. P. Thompson, “Implements of Animals.” 2. Mr. J. E. Howard, “Scies the Caves of South Devon.” London Institution, Finsbury-circus, E.C J. E. Hodgson, “Art Among the Ancies

TUESDAY, FEB. 22ND.—Royal Institution, Albemarle-street, 8 p.m. Prof. E. A. Schfer, “The Blood.” Medical and Chirurgical, 53, Berners-street, W., 8½ p.m. Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Max Am Ende, “The Limiting Dimensions of Girder Bridge Anthropological Institute, 4, St. Martin's 8 p.m. Royal Colonial, the Grosvenor Gallery Lil Bond-street, W., 8 p.m. The Right E. Frere, Bart., “The Union of the Vi of British South Africa.”

WEDNESDAY, FEB. 23RD.—SOCIETY OF ARTS, Adelphi, W.C., 8 p.m. Mr. Charles I “Rivers Conservancy.” Geological, Burlington-house, W., 8 p.m. Holmes, “The Permian, Triassic, and L the Carlisle Basin.” 2. Prof. W. J. Soll Grant, a new Lyssakine Hexactinellid fr Formation of Canada.” Royal Society of Literature, 4, St. Martin's 8 p.m. Mr. W. A. Barrett, “The English Church Music.”

THURSDAY, FEB. 24TH.—SOCIETY OF ARTS, Adelphi, W.C., 8 p.m. (Chemical Section Buchanan, “Deep Sea Investigation, and used in it.”

Royal, Burlington-house, W., 4½ p.m. Antiquaries, Burlington-house, W., 8½ p.m. London Institution, Finsbury-circus, E.C. W. De W. Abney, “One Aspect of Color Society for the Encouragement of Fine Art street, W., 8 p.m. Mr. J. W. Bradley, tion.”

Royal Institution, Albemarle-street, 8 p.m. “History of Drawing-room Music.” (Le Musical Illustrations. Inventors' Institute, 4, St. Martin's-place, Royal Society Club, Willis's-rooms, St. 6 p.m.

FRIDAY, FEB. 25TH.—SOCIETY OF ARTS, John-W.C., 8 p.m. Adjourned Discussion Taylor's paper, “The Participation of Fruits of Enterprise.”

Royal United Service Institution, Whitehall Captain S. Long, “A Study of the T Blockade, as affected by Modern Weapons Royal Institution, Albemarle-street, W., 8. Burdon-Sanderson, “Excitability Animals.” Quekett Microscopical Club, University 8 p.m.

SATURDAY, FEB. 26TH.—Ladies' Sanitary Association of the Society of Arts, 6½ p.m. Dr. son, “Domestic Sanitation or Health Culture III.)

Physical Science Schools, South Kensington 1. Mr. C. V. Boys, “An Integrating Mr. Shelford Bidwell, “The Telegraph of Pictures of Natural Objects.” Royal Botanic, Inner-circle, Regent's-park Royal Institution, Albemarle-street, W., Stuart Poole, “Ancient Egypt in its Conditions.” (Lecture II.)

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,476. Vol. XXX.

FRIDAY, FEBRUARY 25, 1881.

*Communications for the Society should be addressed to the Secretary  
John Street, Adelphi, London, W.C.*

## NOTICES.

## WHYMPER'S PAPER ON CHIMBORAZO.

At the ordinary meeting, on Wednesday, 9th Mr. Edward Whympers will give an account of recent ascents of Chimborazo and Cotopaxi. It is expected that many members will wish to attend.

Whympers, it is proposed to make special arrangements for this meeting, the usual rules of the Society being suspended for the evening. Admission will be by special tickets only, and these will be issued to members in the order of seniority. Should a sufficient number of applications be received by Monday, the 28th February, a special course of arrangements will be made for holding the meeting in a larger room than the Society's own room, otherwise it will be held as usual. The names of members who wish to attend will be registered, and tickets will be issued by the 4th or 5th March. Either one or two tickets will be sent to each applicant, as the Committee may permit.

Members are particularly requested to take care if they wish to attend they must provide themselves with a ticket, as no person, member or non-member can be admitted without a ticket.

H. TREWMAN WOOD, *Secretary*.

## CANTOR LECTURES.

The third and concluding lecture of the second course was delivered on Monday, 21st inst., by Mr. Rigg, M.A., on "Watchmaking." The lecturer urged the necessity of efforts to promote watchmaking in this country; and pointed out the need of scientific, theoretical and practical, in horology. The lecturer demonstrated the construction of repeating and other watches, was assisted by a screen by means of the spheniscoscope and electric light.

Mr. Rigg proposed a vote of thanks to the lecturer, and expressed, in the name of the watch-

making trade, the great pleasure that those who attended the course had received in listening to the lectures. It was now easy to obtain popularity by running down the English trade, and he was glad that Mr. Rigg had not sought such popularity, but had been able to speak a good word for the English manufacturer, who produced the best watch in the world.

The CHAIRMAN (Mr. B. Francis Cobb, Treasurer of the Society), in putting the vote of thanks to the meeting, drew attention to the trade statistics, as furnished by the lecturer, and spoke of them as neither creditable to the trade nor to the country. He alluded to the evil effects of trying to keep any trade as a close trade in the present time, and showed how the great business of supplying clocks and watches to the Colonies had gone past this country. He spoke hopefully, however, of the result of the technical horological education, now working under the auspices of the City Guilds, and he exhorted his hearers not to underrate their opponents, but to take and adopt new ideas from whatever source they could obtain them.

The lectures will be published in the *Journal* during the summer vacation.

## HOUSE SANITATION.

The Council offer the following Medals for the best Sanitary Arrangements in Houses built in the Metropolis, the plans of such arrangements to be exhibited in the Society's Rooms, Adelphi, in June, 1881, and to be sent in on or before 12th May, 1881:—

1. One Silver Medal for the best sanitary arrangements, carried out and in satisfactory working, in a house let out in tenements to artisans, for which a weekly rental is paid.

2. One Silver Medal for the best sanitary arrangements, in actual working, in a house of the yearly rental of £40, or less, to about £200 in value.

3. One Silver Medal for the best sanitary arrangements, in actual satisfactory working, in a house of the yearly rental value of £200 and upwards, to any amount.

4. The houses must be open to the inspection of the Judges, who, in considering their award, will be guided by the suggestions of plans for main sewerage, drainage, and water supply, made under the Public Health Act, 1875. The houses must have been in actual occupation within the last three months, and a Certificate must be given by the occupiers, on a printed form, stating the satisfactory working of all the sanitary arrangements, such form to be obtained at the Society of Arts.

5. The houses may be old, fitted with modern sanitary arrangements, or may be new. They must be within the metropolitan area of the Board of Works.

6. The sanitary arrangements must include the conditions for good water supply, drainage, warming, and ventilation of the house, and precautions taken against frost.

7. The medals may be awarded to the occupiers of the houses, or the lessees, or the owners.

8. The plans must consist of a ground plan and sections, to the scale of not less than one inch to five feet; details of not less than one inch to the foot. The plans may be accompanied by specifications.

9. The names of the architects, surveyors, or sanitary engineers who directed the sanitary arrangements should be given, and Certificates will be awarded to those whose plans obtain the Medals.

## PROCEEDINGS OF THE SOCIETY.

### TWELFTH ORDINARY MEETING.

Wednesday, February 23rd, 1881; the Hon. CHAS. WENTWORTH FITZWILLIAM, M.P., F.R.G.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Brevetor, Thomas, Kimberley-house, 2, Evering-road, Stoke Newington, N.  
Harris, Edward, London, Upper Canada.  
Smith Henry, J.P., Ellingham-hall, Bungay.  
Underdown, Robert George, A.I.C.E., Manchester, Sheffield, and Lincolnshire Railway Company, Manchester.  
Uren, John C., Cornwall-terrace, Penzance.

The following candidates were balloted for, and duly elected members of the Society:—

Bolas, Thomas, 2, The Terrace, Turnham-green.  
Chambers, William E., Eversfield, Sutton, Surrey.  
Courteen, Henry, 336, Clapham-road, S.W.  
Felkin, Robert William, F.R.G.S., Pennfields, Wolverhampton.  
Kirkham, Thomas Nesham, 21, Abingdon-street, Westminster, S.W.  
Lee, Edwin, 43, Devonshire-street, Keighley.  
Le Rossignol, Francis, 1, Gresham-buildings, Basinghall-street, E.C.  
Magniac, Arthur, 36, Hertford-street, Mayfair, W.  
Martindale, William, 10, New Cavendish-street, W.  
Murray, R. W., 179, Upper Thames-street, E.C.  
O'Donnell, William Arthur Maxwell, 4, Gladstone-street, London-road, S.E.  
Parr, Samuel, 7, Finsbury-square, E.C.  
Pheasant, William Craster, 8, Edwardes-square, Kensington, W.  
Raffety, John Henry, 4, The Terrace, Richmond-hill, Surrey.  
Swanzy, Francis, 147, Cannon-street, E.C.

*The paper read was—*

## RIVER CONSERVANCY.

By Charles Neve Crosswell.

Continuous floods, abnormal diseases, a spread devastation, crowned by a successful bad harvests, have brought about a sanitary history, and a cry has gone forth, of David of old, to be "delivered out of the deep waters." That cry has the precincts of Westminster, and the legislative progress begins to revolve once. In 1879, the Duke of Richmond and Gordon already brought in a Bill for the conservancy of rivers, which passed through the House of Commons but was lost in a flood of political expediency. In the previous year, at the instance of the Duke of Wales, this Society, as is its wont, led by a public conference; and, subsequently offered prizes for the best suggestions, with object of dividing England into water-sheds, and organising provision for a supply of water as the first necessity for the health and comfort of the people. The Society's *Journal* with contributions on the part of eminent naturalists, geologists, and engineers, in response to an invitation, whilst the Duke of Richmond above mentioned was the practical and immediate result. In 1880, nature herself came to the aid of the philosophers, and carried the question of the range of theory and polemics, by a series of almost unprecedented floods, which followed upon the other throughout the kingdom. The matter assumed the proportions of a national calamity, and the Duke of Bedford led a deputation to the Minister, composed of a selection of the most distinguished names and conditions of men, who had merged distinctions in the sympathy begotten by the misfortune. This brief historical retrospect interesting as a political lesson, teaching the conclusions of science, the experience of neighbours, and the silent testimony of the occupier's individual sufferings, will not move the public, or rouse the Legislative action. Certain disquieted spirits discern "writing on the wall," but their warning received with indifference, and the public as it always waits, for a portent; for some time in the guise of plague and pestilence they have had it in submerged pastures, cattle, deserted homesteads, vacant farm lands in search of tenants in lieu of corn for farms, broken dykes, and broken heads, dismal forebodings everywhere.

I propose to consider the subject of river conservancy under three distinct heads. First, the conservation of rivers for the purposes of navigation; secondly, for the purposes of utilitarian fertilisation; and thirdly, conservation in the sense of purification, including, of course, preservation and breeding of fish.

The subject is far too wide for the limits of a single paper, and I have condensed my draft by cutting it in half. I have only that I have reserved for my audience this the better half of my reflections.

Two measures are now before Parliament for their object the establishment of Conservancy Boards to effect each of these three objects by methods differing in respect of details, alike armed with powers to rate the districts

ed by their operations. The Government re in the House of Lords is certainly more ehensive than that to be introduced the House of Commons, but there are ionous defects common to both. The s Thames and Lea, with others, are excluded both measures; both err upon the old lines ating new authorities, with arbitrary districts e defined by the Local Government Board, in- ing the inevitable local inquiry, with its train inlocation, law costs, and correspondence. he entrusting the central department with the hange of duties so novel and extensive, and before e limits of any area of jurisdiction can be defined, e Ordnance Survey Department of the United gion must complete its work. The attention he public has been lately called to the startling e that in many districts that survey is still mplete. This is a task worthy of the Imperial ment, for which the Department is in every et qualified; moreover, the cost should be e by the State, and not be cast upon the rate- ns in the several localities. It is alleged that pper Thames Valley Commissioners expended y £5,000 out of their own resources in this ainary survey, that should long ago have been leted as part of a national work.

e functions of Imperial administration end those of local self-government begin, and Department intervene at all in the definition eas, it would find abundant occupation in ating that survey, which is described, on high rity, as in a more backward condition than f any nation in Europe.

h regard to the local jurisdictions to be d by these Bills, Mr. Magniac's measure errs he side of excess, while the Government re errs rather in the opposite direction. he one case we have a redundancy of rities which may clash, and, in the other, inations of several basins, too wide for at control. The Government Bill might e the basins of the Trent, of the Ouse, and e Aire and Calder, within the definition of basin of the Humber. The basins of the e would be within that of the Severn; and if e are included under one general Conservancy d, we shall combine areas which have neither ephical affinity, community of interest, nor ity of cohesion. There is no definition in Bill of the basin of a river, and it is mani- that such rivers as the Wye, the Trent, the Calder, require the supervision of a ate conservancy. Mr. Magniac's Bill, he other hand, proposes, as the unit of a triplet of parishes, or a single muni- borough. A combination of these units itutes a district, and a General Board will almost despotic authority over the basins of e which have their outlets in the sea. The at and limits of such districts and sub- icts is left to the sagacity of the Government ector to determine. They ought, in my ble opinion, to be defined by the Act itself, wise we shall be overlaid by a multitude of e jurisdictions in counties, such as those of ain and Nottingham. The first of these con- 750 separate parishes, besides sundry Town oles, the latter 300 parishes, comprising nine -law Unions. And we are confronted by the

possible creation of 250 separate sub-districts in the county of Lincoln, each having its own limits and independence of action; each moved by its own jealousies and prejudices to thwart and hamper those who are situate below, above, or around them. The General Board, it is true, has the power to restrain mis-directed energies, as well as to enforce the performance of duties required by the Act. How this Board of Control will avail to overcome local obstruction—the inertia and stolidity of the provincial mind—is yet an unknown quality. It is, in any event, a leap in the dark, and a novel experiment in local self-government.

The simplicity of the Government Bill is in accord with the tendency of modern legislation, which aims at concentration rather than the diffusion of local authority. There is, indeed, a maze of jurisdictions to be found on the face of every county, overlapping and jostling each other in most admired disorder. If the Legislature could find time and occasion to determine once for all the unit of local administration, it would cut the Gordian knot of sanitary legislation. Every constituted authority would thus consist of groups or combinations of the units; and we should no longer be bewildered by a redundancy of authority—postal, sanitary, magisterial, and parochial, “the rotten relics of antiquity,” as a profane critic once styled them, without sympathy, or the hope of intelligent co-operation. It was anticipated that a Liberal Parliament would effect this grandest of all reforms, by the creation of County Boards—local parliaments—within the limits of each county, charged with all the administrative functions of local government, elective and representative, and enlisting the services of that wealth and intelligence which now too often keep aloof from the turmoil of parochial politics. Such a creation as this would re-animate the whole system of local administration. Above all, would these bodies be competent to undertake the conservation of our rivers, having their jurisdiction defined by historic land-marks, well-known and understood by the people. The constitution of these local parliaments has been again and again urged in this hall, and I venture to think that the experiment about to be made in Ireland might be advantageously extended to the counties of England, in lieu of a network of complex jurisdictions, to be developed under the cold shade of an Imperial department, and involving the worst evils of centralisation, which must, sooner or later, break the back of local independence, by saddling upon it that modern “Old Man of the Mountain,” the Local Government Inspector.

The Government Bill divides the land to be rated for conservancy purposes into lowlands, midlands, and uplands, contributing in the proportion of one-sixth as a maximum measure of the relative benefits. In Mr. Magniac's Bill there are but two classes, even more widely contrasted. This will tax the energies of the Government Inspector, and throw each district into social fermentation by contests, local and Parliamentary. We are floundering again in the quagmire of local inquiries.

Assuredly it is not the province of the central bureau in Whitehall to indicate the limits of a river flood, or to determine how far this or that land is vitally interested in the maintenance of the arterial drain of every watershed. Desolate

homesteads, and depreciated properties, mark too well the limits and extent of these liabilities. Let the Government pass a Conservancy Clauses Consolidation Act, embodying the general principles and regulations by which all Conservancy Boards will be governed in the future, such as was enacted for the construction of railways, and of waterworks, and for the manifold purposes of public health, and leave the details of local administration to those who are best able, by local knowledge and experience, to determine them. If County Boards were established, they would be the best tribunals to determine these questions of relative rateability between upland and lowland throughout the watershed; and where a river constitutes the frontier line, or division between two or more counties, the conservancy would be composed of committees of the Board of each county, and thereby we should realise the conception of Mr. Stansfeld, when he recommended "simplification of areas and authorities," constituted for all purposes and functions for which those areas are fit.

#### NAVIGATION.

For improving and maintaining the navigation; for maintaining dykes already existing, or constructing new ones; for removing obstructions, lowering dams and weirs; in a word, for all the purposes of repair, of maintenance, and of improvement, these Acts confer ample powers, which are indispensable to every conservancy. It may, however, be asked whether rivers beyond certain limits of tidal waters are now required for navigation at all, seeing the marvellous extension of our railway system in every valley and nook of this kingdom. It is certain that many rivers, once the silent highways of inland commerce, are now well nigh deserted, and if the interests of navigation are of paramount importance in these days, it will be necessary, not only to lead the waters into our rivers, but to keep them there for times of need, when drought shall follow present abundance. It is easy, by a judicious expenditure of money and brain power, so to control the stream, that your river shall be full in ordinary seasons; but to replenish and maintain that stream when the cycle of dry seasons recurs, as it assuredly will, is a much more complex problem. The floods of the past few years should not blind us to the probable recurrence of a season when we shall have too little water rather than too much, whether that deficiency be due to the wholesale abstraction of water for the supply of dense populations, or to the reckless misuse of bountiful rain, as the cheaper vehicle which modern civilisation calls in aid to convey the sewage of those populations to distant outfalls. In selecting such outfalls for the disposal of sewage, engineers are apt to think less of the requirements of the riparian owners than of those of the towns which invoke their aid to rid them of a nuisance. In such cases, it often happens that the waters which should replenish the rivers are diverted from its natural channel to another area, where they may be regarded as a curse rather than a blessing. The late Mr. Cubitt, twice Lord Mayor of London, when contemplating the gigantic scheme of sewage interception projected for this metropolis, used to say that the removal of the waterworks to points above Teddington Lock, and the wilful waste of water as a vehicle of sewage

within the metropolis, would, sooner or later, pair the volume and scour of the Thames through 30 miles of its course; and that some of us might live to see the results of such improvidence. It is rash to prophesy in these days, but when millenium, which we are all fondly anticipating shall arrive, when "*Sanitas sanitatum, et sanitas*" will become not a bye-word but a reality, we shall keep our sewage out of our rivers as the first condition of their purity, and permit rainfall to pass through its natural courses unpolluted, and fitted for the needs of industry and commerce along their course. If our drains and sewers were properly constructed of sufficient capacity, no more than sufficient, towns would supply its own vehicle, thus avoiding the danger of huge elongated cesspools, which are the bourne and brook of our cities into a pestilence.

#### IRRIGATION, DRAINAGE, AND PROTECTING LANDS FROM INJURY BY FLOODS.

For these and analogous purposes, both laws provide abundant powers, in addition to the power of rating the inhabitants of each county in order to supply the necessary funds for the requirements of the conservators. There was no dispute as to the necessity and efficacy of these provisions. It is only when we come to the question of degrees of liability that we can see in our mind's eye a cause of future contention and conflict, but the question whether uplands should bear all remains, and is by no means so easy of solution as has been sometimes contended. Doubtless low lands benefit most by new works, as they suffered most by the neglect of old; they have any event to bear the burden of excessive rain upon the uplands, and this contingency affects their price and value; on the other hand, the lands above the range of floods are benefited by the outfall for natural drainage, and it is known that highlands attract the rain-clouds, and that rain falls upon the hills than upon an equal area in the valleys beneath. This alone would be an argument for not exempting them altogether from the conservancy-rate, if spread over a small extensive area cannot be a grievous burden to any one of it. Though we accept the principle of a rate of liability within certain limits, for the common good of all, I believe that this vexed question should never be adjusted in the turmoil of local inquiries, but must be resolutely grappled with and determined in the serene atmosphere of Parliament. Already there are rumblings of discontent in the fen-country of Cambridgeshire, where great works, involving an annual charge, have recently been executed. It would be unjust to place upon those who have had the courage to take upon themselves an additional burden for the benefit of others who have been supine or parsimonious; and demand has been made for a further sub-division to be termed "protected lands," which have completed local works for their own protection; they are entitled thereby to be placed on an equality with the most favoured districts.

The prevention of those continuous floods, and the effects are too patent to every traveller, but, above all, the most important of the duties which devolve upon these Conservancy Boards. We have been warned, by an eminent authority, that

sents "upon which floods depend are entirely out of the reach of human interference." The maker, of course, referred to excessive floods, but we at once admit, without reservation, that whether the salt ocean, nor the sun's heat, which constantly evaporates it, will be within the control of any conservancy. There is no "reign of law" in nature beyond the reach of the Acts of Parliament, and to that law we must ever submit. This self-same salt ocean, under the sun's influence upon it, have worked for good, and for the same almighty power, from primeval times. The question for consideration in these latter days is—What are the causes which have made inundations—once rare, and only to be collected from the memory of the inhabitant—the normal condition of the lowland counties? On the one hand, it is said that due to the perfected system of land drainage, in the interest of agriculture, which carries down the rainfall from upland and midland with much more speed and certainty than formerly, whilst the capacity of the river bed, which once was able to contain the flood, is silted up from day by day by mud, and *debris* from the upper basins. On the other hand, it is asserted that drainage increases the absorptive power of surface soils, and that the rainfall now soaks into the pores and crevices of the earth, as formerly it ran from saturated surfaces straight into the river, when once the shallow ground was filled, and downward filtration prevented. Whatever force may be due to either element, this will not account for the phenomena of so frequently recurring of floods, where no floods within the memory of man; and to determine the question, finally, would require not only diligent investigation, but also data and statistics which are not yet forthcoming, for the use of scientific demonstrations. Conclusions vary according to the character of soil and strata; and the observer holds by the result of his own personal observations. Whenever it rains for twenty-four hours, men look to the too familiar pages of the daily journal, and read a calamitous account of floods in the Midlands, as we were wont to do with grim misgivings for a list of "wrecks and casualties" after an equinoctial gale. It may be that in these days of newspaper enterprise, of local correspondents in every town, endowed with strong imaginations and irrepressible curiosity, nothing is lost in the relation of it to the daily reader, who scans, with his daily bread, a page of "moving accidents by flood and field." The shepherd tells his tale of woe to the interloper, and there is now-a-days a craving for sensational news which neither existed nor was dreamed of in the philosophy of our forefathers. It may be the march of civilisation, but there is no hiding a light under a bushel; our virtues and our social evils and misfortunes, the incidents of every trade and every occupation, are proclaimed from the house-top without reserve or extenuation. It was far otherwise a century ago. The floods of Yorkshire had abated before their name was known in London, and dry land had been sown in the valleys of Somerset before the citizens of Carlisle had ever heard of the deluge. In this year of grace, the telegraph repeats each harrowing detail with painful iteration.

We are, however, not alone in our struggles to control by human skill the forces of nature; this has been done successfully in Holland, where the people live deep down in the hold of a ship, as it were, ever on the watch for the slightest sign of crack or leak; in Italy, also, upon the plain of Lombardy, the yellow floods of the fruitful Po are curbed, controlled, and utilised for the beneficent purposes of man; and with all our self-glorification as an eminently practical people, it is to these two nations after all that we shall have to look for practical lessons in the art of river conservation. Time fails me to describe how the sturdy Hollander won his birthright from the sea, how he kept it through centuries of toil and persecution; how the floods of Rhineland have become a river of wealth and fertility, and the Rhine delta converted into a luxuriant garden; but they who run may read, and those who aspire to local fame and usefulness, and to serve the State upon these new Conservancy Boards, will find the system of scientific drainage, as developed in the Drainage Unions of Holland, the best model for their imitation. Mr. J. Clarke Hawkshaw has described it in a luminous paper, which will be found in the *Journal* of this Society, vol. xxvii., p. 848. The Government may well take a lesson from that cradle of self-government and independence, by establishing a central department of water engineers similar to the College of the "Water-Staat" in the Hague, of which Mr. Dirks is the head. This department deals with all matters relating to the flow of rivers, and the levels of floods, and controls the drainage of the polders and fens of Holland from a common centre, as Count Moltke directed the operations of a grand army from the table of his bureau; an example in every way worthy of our imitation, which would ensure a succession of trained and experienced men, directed to this particular branch of engineering science.

Practical men have long been of opinion that something like this system of central control should be adopted along the course of our rivers—that every weir and lock should be connected by telegraph, governed from some point of vantage to insure concerted action—so that whenever the approach of a flood be announced, a comparatively empty river would be ready to receive it.

There are yet other causes of flood and inundation, which have not escaped the observation of men like Mr. Parker, of Oxford. One, and not the least important, is the reclamation of the numerous meres, like Oxham Mere, on the Thames, or Whittlesea Mere, in the valley of the Ouse, and the embankment and cultivation of large tracts upon each river bank, which formerly, in times of flood, were always covered; and at other times and seasons were utilised as commons of pasture, for the use of all. Another cause is the silting up of the river channels by the *debris* and detritus which the neglect of past years has allowed to accumulate. To the first I attribute the greatest importance. These meres and marshes once marked the course of every stream as it approached the sea, and became reservoirs for superfluous waters, and safety-valves to the surrounding districts, serving the same purpose as the bosom lands of Holland, which are maintained with the most vigilant supervision for the storage of flood waters in the lowlands around them. Such were

the saltings of Essex, at times covered by the waters of the Crouch and Blackwater, affording, in dry seasons, a precarious pasturage to the neighbouring communities. Where these wide reaches, or ancient morasses, have been reclaimed, embanked, and won from the sea, we find too often the walls and dykes neglected and out of repair, and the storm of the 18th of January has awakened us from a sleep of half a century, and made the inhabitants of some districts acquainted with misfortune who dreamed that they had kept themselves safe from inroads of the sea. Time forbids me to enlarge upon this topic, but the subject is in good hands, and only too ripe for the attention of the Legislature.

In the valleys of the Tame and Trent, large tracts of farm and meadow land have become an inland sea. These rivers, choked with mineral and manufacturing filth, leave behind, when they do retire, a film of poisonous filth to kill the herbage, and infest the soil with sedge and "tussock" grasses, which convert the finest pastures into an unprofitable morass.

Something is being done, we are told, by the Thames Drainage Commissioners, under their special Act, to maintain that river as nature intended it to be—the main drain of the upper valleys; and this brings us to the inquiry so often made in this hall—Why is it that in all these measures of sanitary preservation the metropolis and the Thames are exempted by special saving clauses? In Mr. Magniac's Bill, the Thames, the Lea, the Mersey, the Medway, the Tyne, the Wear, and the Tees, representing well nigh half the watershed area of England, are excluded. The Government Bill is less curtailed in its operations, but both measures are careful not to disturb the rights of the Crown, or the ancient privileges of the Lord High Admiral of the Kingdom. It is, however, to the Thames I would particularly direct attention. There is a mysterious sanctity about this river and the precincts of the metropolis. It is a kind of "Alsatia," like the old sanctuary of Whitefriars, with its benefit of clergy outside the pale of the constitution, and beyond the reach of the common law. In 1848, the metropolis and the Thames were specially excepted in the preamble of the first Public Health Act, and the duties of drainage were confided to the charge of certain Commissioners who have "damned themselves to everlasting fame" by directing the sewage of London and its suburbs to be passed into the River Thames as the best available means of disposing of a nuisance. Twenty years later, the Conservancy Acts were passed to compel the unfortunate victims of misdirected zeal to take it out again, and retrieve, if possible, the ancient purity of the stream. From the Pollution Act of 1876, the Thames and the metropolis were again excepted; and in these two measures now before us, the Thames is exempted, although it is admitted, on all hands, that the Conservators of that river have every power for good or evil, except that which this Act would give them, namely, the means of rating the owners and occupiers who are to be benefited by their operations. The tolls of navigation, and the subsidies of the water companies, do not suffice for all the purposes of the Thames Conservators, and they would gladly have the powers which *these Bills* would confer upon them of providing

increased funds for necessary improvements. And it is, the want of means to do good deeds is the ever ready excuse for leaving them undone. It certainly cannot be argued that the provisions of the prevention of floods are not required for metropolitan waters. Bermondsey and Windsor, Lambeth and Hampton, would tell a far different tale and the irony of the situation is complete when we see the Royal domain of Windsor faring no better than the squalid dens of Rotherhithe; whilst read in the last official report of the Port Medical Officer of London, dated September 1st, 1880, that there are still 348 foul outfalls within the limits of his district; nearly every one of which implies a distinct violation of the River Pollution Act. As to the condition of the river below Barking and Crossness, the writer of this paper has denounced it too often in this hall to make it other than a thrice-told tale to your audience. It may be stated, in the interests of navigation, before we quit the subject of the Thames, that the dredging operations of the conservators during the past few years have made the lack of water more conspicuous.

#### PURIFICATION.

The last branch of this inquiry is conservation of the purposes of purification, and the preservation of fish as food for the people. It is often said that purification is a misnomer, that it is impossible to purify water once polluted by sewage, and that miles of river flow would not suffice to destroy, by oxidation, the germs of infection, where they are. When I speak of purification, let it be understood that I mean "comparative purification" only; the allegations above mentioned are well founded, but it would appear to be the logical sequence of the opinions held in high quarters, that our rivers should not any longer be the sources of water supply for the people, and that the Thames and Lea must be unfit for the supply of water for food. That they are polluted by sewage we can dispute, and in the eyes of sanitary specialists, the baneful results of that contamination become more patent every day. But the Government measure expressly provides for the storage of water for drinking and other purposes, and the new Conservancy Boards may store water thus stored from time to time; this at once involves the power to clarify and purify as far as practicable the water to be stored, and, consequently, we find that both measures provide for the enforcement of the Rivers Prevention of Pollution Act, 1876, conferring all the powers of a sanitary authority for such purposes. Those who know how far that Act has fallen short of the promise of its inception and enactment, this is indeed a step in the right direction, and the appointment of a free, fearless, and incorruptible authority to insist upon obedience to that Act, to redeem it from the reproach hitherto cast upon it of a lame and impotent piece of legislation. In November, 1877, the Local Government Board recommended this Prevention of Pollution Act to the attention of all sanitary authorities throughout the kingdom, but the sanitary authorities turned a deaf ear to the suggestion, and when the Act came into operation at the beginning of 1878, it was found that in the rural districts, the owners of small towns upon the Local Boards took good care that

which they had compounded, should not be met at the bidding of Government Inspectors or local sanitarians; whilst in the towns the manufacturers themselves, who were the principal offenders, usurped the reins of local government, and with sullen immobility declined to step forward for their own impending execution. Manufacturers themselves being the most offenders against the obnoxious Act, it is not for surprise that they showed no alacrity in its provisions. When these measures receive the sanction of Parliament, we shall witness a momentous change for the better throughout the country. Men above the petty temptations of interest, and eager only for the common good, rich and poor alike, will intervene, under the Act, to stay the continuance of old and to establish the establishment of new sources of pollution who can doubt that that intervention is very much required? Sewage contamination, in form, is poisoning the fish of every river, the Tay to the Dart, and the precious food of the fish perishes, choked by the refuse of cloth factories run to waste in every river pool. Fisheries are carried away, and their most constituents lost in solution in their progress towards the sea; and when we reflect that the soil to the acre is no uncommon dressing in the Thames valley, we contemplate the use of fertilising material with dismay. It is indeed "matter out of place," and which was intended to enrich the lands, and which now only serves to defile the waters. If this be an accident to high farming and scientific agriculture, if this be beyond the help of human skill, a serious matter for our consideration, we are justified in storing river water, at all our lower reaches, for the use of man? and the valleys it may be possible to obtain sufficient purity from the rills and in this regard, the measures will be found to be worthy of all support. The polluters, by the refuse of mills and manufactures, however, the *pièce de résistance* of progress. It has baffled the energies perplexed the minds of economists, and can paraphrase the celebrated line of the poet, "There is the respect which makes of so long life." Every Government plunges into the slough of despond, and inside and outside Parliament have to postpone the question to a more convenient season. It is not wise to harass interests, commercial interests, just on the eve of a General Election, and gratitude for political favours to come, make men wary of interference during the existence of a Parliament. The logic of facts is too strong even for the House of Commons, and the Court of Chancery steps in to the rights of riparian owners, even where the Act halts in providing a remedy. We have a notorious tale of injunctions and information from the Attorney-General, on every side there is a cry for help to arrest the vengeance of the mills and factories in some of our most important industries have the possibility of extending over them. From the Calder, the Ribblesdale, from the Medway, and from the unfortunate millowners, in their emergency appeal for help—financial and scientific

—to save them from the threatened injunction. Fortunately, it has come to pass in the very nick of time, now that the Government have resolved to enforce compliance with the law, that in the same Parliament which is about to give the powers of compulsion to new Conservancy Boards, a Bill has been introduced, and read a first time, in the House of Lords, which offers a way of escape to those who care to seek it. This Bill is called the Manufacturers' and Millowners' Mutual Aid Association, and our Chairman, to-night, is one of its most zealous promoters, representing as he does interests largely identified with the commercial activity of Yorkshire, and suffering from the pollution of one of their largest rivers. The objects of the Bill are simple, viz., to provide the means for enabling manufacturers and others to comply with the provisions of the Rivers Prevention Pollution Act, 1876. "It is capital we want," say the mill-owners throughout the country, "science and engineering skill alone will not suffice, the experience of the past has taught us to utilise our waste, and we have taken to heart the lesson. We can retain that waste, which is really wealth disguised, if we had the capital to erect the necessary works and machinery; we only want time and the forbearance of the Government for a short while longer to lift us over the dead centre of our difficulties."

The effect upon our rivers, if this resolve were carried into action, would be immediate, and the undertaking of this company becomes, in that respect, an enterprise of national importance. It seeks powers to lend money, and supply the means which scientific skill and experience have disclosed, to keep pollution in the form of mineral and factory refuse out of our rivers, and to convert it to use and profit. The provisions of the Bill are analogous to those of the Land Improvement Act, furnishing a means of judicious investment, secured by the best of all assurances, in the development of our commerce and manufactures, and the improvement of mills and similar premises by outlay of capital to the mutual advantage of both landlord and tenant. The loans will be repaid over a period of years with interest, and the series of instalments will become a charge upon both land and premises thus improved, until final redemption. Such a measure as this is but a corollary to the original Act, and, with the co-operation of the Local Government Department, whose work it is designed to supplement, it will become an instrument in the hands of authority to compel the observance of the law. To Conservancy Boards and other similar corporations it will be a welcome ally, and will afford a ready reply to the manifold excuses which have become the stereotyped apology for every delinquency. "If, sir, you have the will to comply with the Act, there is the way," will be the cogent answer to all such protestations.

We must go back to the times of the Tudors for the first Conservancy Act, and it may be left to the Victorian age to complete the series. We accept these measures gladly for the good that is within them, and as an earnest of still better things to come. Meanwhile these Conservancy Boards, which they propose to constitute, have one distinguishing merit, they are thoroughly representative bodies, based broadly on the will and necessities

of the people, and they will be sustained by co-operation of all classes, urban and rural, for the common good. They will provide for drainage of all lands, high and low, inland or adjoining the sea, and under them the interests of owner and occupier, mill-owner, and merchant, will be equally protected with unity of purpose, and economy of administration. The evil of splitting up the country into partial jurisdictions, and the proverbial fate of divided councils, is thus avoided.

These are great gains, and we hope that the newborn zeal of our legislators will not cool; that Parliament will rise to the height of the great argument, nor stay its hand until the neglect of generations has been repaired.

#### DISCUSSION.

Admiral Sir Frederick Nicholson, Bart., G.B., as chairman of the Thames Conservancy Board, thought he ought, in justice to that body, to say a word or two. The question was one of complexity, and it was very difficult to make clear in a short time the legal position of the various bodies which had to do with the Thames. The portion of the river above Staines must always be divided from that below, the latter having been in the hands of the Corporation of London for many years; but in 1857, the Conservancy Board was constituted, and that portion of the river was placed in its hands. In 1860, the river above Staines was found to be in such a lamentable condition, that it was necessary to place it in the hands of some governing body, that being the portion where the greatest difficulty with regard to floods arise, and it was then placed under the Conservancy Board, which had an additional number of representative members added to the Board. With regard to the navigation, the Conservators had already spent about £100,000 above Staines, in large repairs and new works; and the locks and weirs, which were crumbling to pieces, had now been nearly all repaired. Simultaneously with this, attention had also been paid, as far as possible, to new weirs, in order to mitigate floods. Only a few months ago a new weir had been built above Hamley, which received a very critical examination by a very distinguished officer of Engineers, who had had charge of irrigation works in India, and who acknowledged that it was a most excellent weir for the purpose. But there was always this difficulty, that the moment anything was done which improved the lands above, those below began to cry out for the same advantage, and so they went on from one expenditure to another, until they came to the end of their purse, for money was, after all, the great key to many of these problems. As to navigation, it was quite true, as Mr. Crosswell had said, that owing to the competition of railways, it did not increase as it might; but above Staines it had been much improved. Within the last two years they had placed a steam-dredger on the river, and were gradually clearing away many old obstructions, which no hand-dredger could deal with. Besides the Thames Conservancy, there was another body, called the Thames Valley Drainage Commissioners, which arose in this way. In 1870, the Conservators had a Bill before Parliament, and were anxious to do something to improve the district around Oxford. Owing, however, to reasons which he need not go into, the landowners thought they could do the work better themselves; the Conservators had to withdraw certain clauses from the Bill, and, a year or so afterwards, an Act was passed constituting the Thames Valley Drainage Commissioners. Their jurisdiction extends from fourteen miles below Oxford to a long way above Cricklade. They had had great difficulties to contend with, they had spent a great deal on preliminary surveys, and got an elaborate report from Sir J. Hawkshaw, suggesting an expenditure of £120,000 as the only thing which

would cure the evils; upon this they were rash having already rated the owners and cover it as an acre for preliminary expenses. At present, however, the Thames Conservancy correspondence with them, and were not without that, if some means could be devised for raising something more might be done for that part. There was one source of obstruction which the power of dealing with, and that was the old custom which very often were obvious causes of it could only say that, as far as their powers went, the Conservators had done their best, as experienced engineers, to mitigate the evil. With regard to purification, there was again amount of complication. The Conservancy powers, but within the metropolitan area, for to Crossness outfall, the river in that respect control of the Metropolitan Board of Works. Chiswick and below Crossness the powers of conservators were very large, and he was glad to say that above the intake of the water supplying London, there was no sewage of the river. The various local authorities induced, some at a large expense, to come to divert all the sewage, the last works being those at Oxford. The Conservators his reports from their inspectors, who were visiting the works, and with regard to itself, they were all satisfactory. With retributaries, there were certain small sources of pollution which they had been looking carefully the last few years, because, under the Act of 1864, they had power with regard to pollution over the of the Thames to the distance of ten miles almost every instance they had stopped matter flowing into them. But they were points by legal difficulties. Only the other day had a case on the Colne, where they proved that the matter was obnoxious, that it was Colne, and that in four hours, whatever the water, would reach the Thames, yet the trustees held that they had not proved, in the Act, that "it was likely to go into the Thames," the summons was dismissed. He did not know on the question of the outfalls at Crossness had had a very expensive arbitration with the Metropolitan Board of Works, costing them about £10,000, which they were unsuccessful, because they were there to the question of navigation, and not directly into the question of pollution. The question have been raised before the arbitration result would have been different.

Mr Willis-Bund (chairman of the Sewerage Commissioners) said his Board did not look either of the Bills to which Mr. Crosswell alluded with much pleasure, and his own opinion they would make matters worse than before both as a landowner and resident; for as should welcome both measures, as he must lead to a vast amount of litigation, could not have drawn a Bill more to the interests of the profession than introduced by the Government. One stress was to a new authority being created that they were already clogged with a Drainage Board, Navigation Commission, Board of which he had the honour to be which did what it could, with limited power to prevent the pollution of rivers. Except that where there were several distinct would only talk and quarrel, each with authority of the others. He objected to the institution of the proposed Board, and to the given to it. The Bill stated that due provision be made for the representation of owners, it possible to have a Board with no owners, without the same time they were to pay the

work. There must, in fact, be a large amount of, and very inadequate representation. He also objected to the classification of lands. He could understand two classes of lands—those which were benefited, and those which were not; but he could not understand a third class between the two. Of course, all those which were benefited ought to contribute to the cost, but it was impossible for a Local Government Board Inspector to divide a watershed like that of the Severn in a satisfactory manner into these three classes. In the midst of the uplands, there were lands which were not flooded, and in the lowlands there were portions which were not damaged by floods, and these ought to be treated with the uplands. Again, the Bill proposed to give power to tax every acre of land in a county—because all land was in some watershed—and that was, in his opinion, a power which ought not to be given. What was wanted was a power to set aside once to clear streams, and get rid of floods; and the powers proposed included the storage of water for the construction of arterial drainage. As to the Severn, he contended that it was a separate matter from the other rivers, and the former ought to be left to private enterprise. He thought the powers given should be used in the first instance to inspecting and regulating, and calling on the owners to do the necessary works, and in default the Board might do it. In addition, some system of communication, which had been suggested, by which preparations might be made in time for getting rid of the surplus water could easily be devised. But instead of that a very ambitious scheme was prepared, which would lead to a deal of litigation and expense, much of which might be thrown away. He had seen many attempts made under the Rivers Pollution Act, and he quite understood the necessity for some public body being set up for doing this, but here the Bill fell far short of what was required, and he hoped when the Bill came from committee it would be considerably amended, so that the Board might act in a more summary manner, something like an injunction in Parliament to stop pollution. If you had to write to the Local Government Board, and take first one step and then another before doing anything, the mischief was done. As a town near the source of the Severn where pollution was taking place, filling up the bed of the river, and his Board determined to take proceedings, he first placed, they had to give the offender two months' notice. He replied, that in two months he had done all he wanted. When the time was taken proceedings in the county court, but the case was then done, and as the county court judge had decided the case for two months more, in order to bring the case before the Acts of Parliament, he advised his Board to drop the matter, and not spend any more money which was already done. What was wanted was to interfere sharply and decisively when a pollution was committed, or about to be committed, and to enter into a long correspondence with the Government Board.

Mr. Tolstoy thought it would tend to the prevention of floods if the rain-water which fell on each side of the river was utilised for domestic purposes, which might be done by rejecting that which fell first and washed away the impurities.

Mr. Neel asked Sir Frederick Nicolson if the sewage from Reading, Windsor, Oxford, and other towns which had not passed into the river, what became

of it. Mr. Neel said he was one of the Conservators of the River Lea, and he might make identically the same statement as the chairman of the Thames Conservators had made, with regard to the Thames above the intake of the water companies, and in the same sense. He hoped, therefore, Mr. Creeswell would be able to withdraw the statement he had made about the water of those rivers not being fit for the consumption of the metropolis.

Mr. G. J. Symonds, F.R.S., said he was sure Mr. Creeswell would agree with him that 1880 was not by any means the first year in which floods had been conspicuous. There had been half a dozen exceptionally wet years, which led to exceptional floods, but he hoped it would be recollected in the House, that this was only a temporary phenomenon, and that there was no reason to suppose that the distribution of the rainfall had permanently changed from what it had been for the last 150 years. In all probability, just as they had had successions of dry years and of wet years in the past, so it would go on in the future, and he hoped the arrangements now proposed would not go too exclusively on the hypothesis which just now prevailed, that water was a nuisance, or they would soon be crying out in the opposite direction. In 1868, there was a terrible outburst, especially in the Midlands, that no end of damage had been done by draining too much, for the land was so dry they could not get any grass to feed the cattle. He was very glad to see the announcement in the *Times* with regard to the completion of the Ordnance Survey, and could not understand why there had been so much delay, unless the Department had been devoting too much attention to the survey of Palestine and the measurement of the Pyramids, and neglecting duties more important nearer home. He did not agree that railway communication had rendered water navigation useless, and hoped it would not be the case, because the competition of canals was most important as a check on the charges of railway companies. There was no doubt it would have been much better if London had been sewered with smaller sewers; but, after all, he did not think Londoners would like to see the whole of the rainfall, with all the filth from the streets, following merely the natural channels, which meant, he supposed, down the sides of the streets. If such were the case, it would not be very pleasant to cross Pall-mall, with all the filth from Regent's-park, Portland-place, and Regent-street running down. He did not pretend to be a lawyer enough to have gone through these Bills carefully, but, looking at it as an outsider, he thought they would come to grief over the question of rating. As was generally the case, local and personal interests would come to the front, and, instead of fighting the matter on the engineering merits, it would be fought out on the question whether parties should pay a high rate or a low one. One thing, however, seemed to be overlooked, that the highlands were the real sinners; they produced the bulk of the water, and why should not they help to pay for getting rid of it. There was no doubt in his mind that, if the rivers were properly cleared out, a much more rapid discharge for flood-water would be provided. Again, in old times, it was understood that much land on each side of a river was wash-land, liable to be flooded, in times of wet weather, but now-a-days people built upon this land, and then raised a great outcry when they were flooded. He was glad to hear the suggestion as to opening sluices, &c., and having telegraphic communication at the different weirs, and locks for that purpose; it was one he had made some years ago, but it was only following the example of the French, who had done it long ago. But even assuming the river to be quite free when a flood came down, it would not make so very much difference. The Thames Conservators were always wanting funds, and he hoped some means would be formed for giving them larger means to carry out their operations. As to the fish, he

Mr. Nicolson said it was disposed of chiefly by the fish. The solid particles were applied to the land, and the Conservators had a careful investigation made of the overflow which might pass in. They were by the chemists, who analysed any samples which there was any doubt, that they were fit to pass to go into the river.

thought Mr. Creswell must be a fisherman, or he would not attach so much importance to this point, for any amount of food they might obtain from the Thames in this way would be as nothing compared to the quantity which was constantly thrown away, simply for the purpose of keeping up prices at Billingsgate. Mr. Band had objected to landowners being taxed to provide water-storage, but on the other hand he had heard complaints that those at the head of a river would be able to store up the water, and to sell it to towns lower down at a profit.

Mr. Baldwin Latham agreed that the multiplication of authorities, as proposed by the Bills referred to, would not tend to a useful result. On the other hand, there were great objections to giving conservancy powers to urban and rural sanitary authorities, they being the chief sinners with regard to pollution; and any Central Board elected by the minor Boards would be open to the same objection. The question of taxation would be a very difficult one. It was quite true that the highlands were the flood producers: Sir J. Hawkshaw's rule was that the rainfall increased 3 per cent. for every 100 feet of elevation, but, in 1879, the rate of increase in many places, according to his own observation, was 10 per cent., and scarcely anywhere under 6 per cent, which gave some idea of the enormous amount of floods in that year. Last year the increase had not been so great. But though this was true, the lowlands were valued, taking the contingency of floods into account, and, therefore, if the whole area were taxed, the lowlands would be benefited at the expense of the others. Therefore, in any public measure for improving the lowlands at the general expense, the Conservancy Boards should have power to acquire all lands at the present rental, so that hereafter the district which was to be taxed should have the benefit of the improvement, and not allow them to be pocketed by the landlords. The pollution of rivers was a matter which demanded urgent attention, and though they had heard that the Thames was entirely free from pollution, he thought the statement must be accepted with some reservation. People had very different notions as to what constituted pollution. On the River Lea the works were not so perfect as in the valley of the Thames, but even there, in many places there were large traps and overflows, called storm-water overflows, which in times of heavy rain discharged the sewage of the district into the Thames. There were also many tributary districts, which at the present time were undrained. This question of purification was of great importance, though it was much lost sight of in rainy seasons, these being the most healthy. In fact, the health of London was in proportion to the quantity of water which passed down the Thames. The Bill to which Mr. Creswell had alluded, in which he was in some degree interested, was intended to put manufacturers in the same position, with regard to utilising their sewage and refuse, as local authorities were, giving them power to borrow money for the necessary works, and spread the payment over a number of years.

Sir F. Nicolson said he was quite aware that there were many storm overflows within the metropolitan area; and there, no doubt, sewage came into the river; but, as far as he knew, there was nothing of the kind above the intakes of the water companies.

Mr. Peregrine Birch said the Government Bill ought to be called "The Surface-Water Disposal Bill," for at present no power existed for any authority to deal with the surface-water; and that and the sub-soil water was the great difficulty. Some such measure as that now contemplated would, therefore, be of the greatest use; and it would be advisable not to make the district too large; for it was very difficult to get a large area of one opinion. If the rural or sanitary authorities were not large enough, they could combine, as they did for sanitary

purposes. He should certainly advocate power given to an authority for a part of a basin for a whole basin. He did not believe in the merit of lowlands, midlands, and uplands, but divisions were made should be arranged before a trust was formed, or, as soon as they began who should pay, the majority of the ratepayers come to the conclusion that no work was necessary. He was pleased to hear, on the part of Mr. Sewall Read, that subsoil drainage increased floods, for that had always been his belief. He had no doubt, either, that a great deal of belief that floods had so much increased of late was owing to the improved methods of counting, for there were records of floods 50 and 100 years as high as anything we have had lately, and areas covered must have been as large. He thought much would be gained by telegraphing had seen boats rowed up the Thames over so that if they were removed altogether it made any difference in the level of the water. He sketched out five clauses for enabling sanitary authorities to construct works for the removal of a subsoil water from their districts, which he should be added to the Government Bill.

Mr. Cutler remarked that one point of importance had not been touched upon at all, viz. portance of rivers as a source of power. From Teddington, there was a fall of 70 or 80 feet power thus at command was utilised to some but not nearly so much as it might be.

Mr. Grantham said he was appointed as under the Land Drainage Act of 1861, and he had inspected many districts, where questions this Bill dealt with would arise. The provisions were very complicated, and his experience led him they would not work. At the end of his career for the Lords' Committee, in 1876-77, were one of which classified all the rivers of England according to their areas, and they varied from square miles to three. The medium-size would be comparatively easy to deal with, very large and very small ones would present difficulties; the small ones would be amalgamated, and the larger ones divided. He was the inspector appointed to fix the of the Upper Thames Valley Drainage, a map made on the 25 inch scale, which was reduced, and a contour line was put on it of the highest known flood, and that was its limit. As to the taxation, there was a great made in the Bill, the true principle being lands according to the amount of benefit derived from the works undertaken. In Ireland this was by a valuation of the land before and after, this would be very expensive, still it might be the aid of local knowledge.

Mr. Creswell, in reply, summed up the points in the discussion, with most of which he expressed himself much gratified that everyone who had taken part in it was a reasonable man. He was much delighted at the statement by Sir Frederick Nicolson, in which he was by Mr. Noel, but he thought those gentlemen little too confiding. If inquiry were made of owner on the Kennet, just where that river crosses the Thames, near Reading, as to the condition of it after a heavy rain, he did not think his report would be so satisfactory as to the perfection of the sewer. Mr. Band was quite right in saying there was enormous field for litigation, and that he would avoid. With regard to the Lea, he heard at the inquiry, the evidence of Major Leese who lived in the Lea Valley, and he gave a satisfactory account of it, and talked of "the which was a polite phrase for certain sin

ness opened at night, when the Conservator looked out. He admitted the force of his objection to the whole of the filth of its being washed down the gutters, but that by proper scavenging, and, in practice, water would not be carried in open gullies, red channels much smaller than the *cloaca* existing. There was no doubt, as Mr. Cutler noted, that a great deal of the outcry arose from people's own folly in building situations. For instance, Nottingham, 100 ad 7,000 inhabitants, and now had 120,000, of whom lived in rows of dwellings along the Trent, built on land which was for half the year. As to the fish, he quite the disgraceful proceedings now common be stopped, but when that and all other abolished, there would be no need to have a dish room any longer. Mr. Latham's valuable storm overflows showed the importance of the rainfall from the sewage wherever it was from these storm overflows that the of contamination were derived; and the of the Thames were not by any means so Conservators imagined. However, when of the decision of the magistrates at Ux- could only wonder how any Board could duties. Mr. Cutler had certainly called an important omission, but, as had been beginning of the paper, he had been obliged at least he should have liked to bring forward. ies connected with taxation to which Mr. ad alluded were present to his mind, and efore, suggested that they should be ad- rliamentary authority, and not left to local d disputes.

man moved a vote of thanks to Mr. Cress- was carried unanimously.

## MISCELLANEOUS.

### PRODUCING BOMBYCES REARED IN 1880.

By Alfred Wailly

(Sécrétaire de la Société d'Acclimatation de France).

been seen in my report, published in the *Society of Arts*, Feb. 13th and March the cold weather in 1879 had the most effect on the rearing of exotic Lepidoptera. fine and warm weather we had during the agust and part of September allowed of the aring of several species in the open air; but wet weather, lasting till about the end of e same effect on most species, as in 1879. of *S. Promethea*, for instance, which gener- at the end of June and beginning of July, emerged before the end of August; one, emerged on the 7th of September. Except- the Indian species did not emerge at all. *selene* moths were obtained at intervals; the ined in the pupa state. No pairing could

The same failure attended *Attacus mylitta* race), of which I only obtained nine moths, th of August to the 7th October, giving me of obtaining fertile ova. A singular fact *Attacus mylitta* is, that some cocoons placed use at a gardener's, in April, did not produce ill August, too late to rear this species, if ould have been obtained.

d of February, 1880, I received from Cal- cocoons of *Attacus mylitta* (Himalaya race), which had died in transit, but none had later on, April 19th, I received from Major

Coussmaker a tin box containing 100 *Mylitta* cocoons of the Bombay race, more than two-thirds of which had emerged on the way. The tin box had evidently been kept in too warm a place, and the metal had quickly communicated the heat to the cocoons. From the remaining cocoons of this Bombay race I obtained several fine moths, from the middle of May to the beginning of July, but, as with the Himalaya race, no pairings took place, the weather being too unfavourable. I had to keep them in a room.

For two years I have had a series of disasters, owing to various causes. The greatest difficulty is to obtain the cocoons alive from abroad; the next great difficulty is the struggle against the climate, which has been my greatest enemy here during the last two years. Artificial heat, unless pure air and a free ventilation can be obtained at the same time, cannot replace natural heat. The reverses experienced during the last two years in my attempts to reproduce and rear these splendid silk- worms and other Lepidoptera have been beneficial to me in one respect—they have given me valuable information, which I should never have acquired had every- thing succeeded according to my wishes, although I sincerely hope these fatalities will not occur again, at least on such a large scale.

The species of silkworms which I placed on trees in my garden during the magnificent month of August, were *Cynthia*, *Pernyi*, *Prometheus*, *Cecropia*, *Polyphemus*, *Luna*, and *Pyri*.

The *Cynthia* worms thrived remarkably well on the *Ailanthus* trees; so did a few *Promethea* on a small lilac tree, the first time I tried the latter species in the open air. I never remarked that the sparrows destroyed any *Cynthia* worms; the *Promethea* worms (a very closely allied species) were equally spared by them. But it was not so with respect to the other species, of which the sparrows made a wholesale murder this last summer (1880). Excepting the year 1879, when the rearing of most species was absolutely impossible in the open air, I had previously succeeded in obtaining cocoons of several species besides *Cynthia*, although I could not protect them from their terrible enemy, the sparrow.

My object in thus rearing, or attempting to rear, these silkworms on trees in the open air, is, of course, to test what we call their *rusticité*, i.e., their hardness or capacity to resist the English climate; but birds must certainly be guarded against.

*Actias luna* (North America).—This species I bred this year for the first time, and I obtained a complete success. I think it is one of the easiest species to rear. The larvæ were fed on walnut, some of them being kept under large bell-glasses, till they formed their cocoons, which are of very thin texture. This species is of no value as a silk producer, and cannot be called a silkworm, but it is very beautiful; the perfect insect, like the Indian *Selene*, resembles a swallow-tail butterfly of a yellowish-green; it is smaller than *Selene*. Other *Luna* larvæ thrived equally well on a nut tree in my garden, with *Polyphemus* and *Cecropia*, but, as stated before, the sparrows destroyed them all, when in the third and fourth stage. I had a large quantity of *Luna* cocoons from America, and the moths emerged from the beginning till about the end of June. I obtained twelve or thirteen pairings. In the first two stages there is a striking difference between the larvæ of *Actias luna* and those of its Indian congener, *Selene*. *Selene* larvæ in the first stage are dark red, with a broad black band across the middle of the body; in the second stage, they are of a lighter red, without the black band; in the other stages they are green like *Luna* larvæ. *Luna* larvæ are green in all their stages; in the first stage, of light or whitish green. When large, the tubercles on *Selene* larvæ are bright yellow, and on *Luna* larvæ, of various shades of red or crimson.

*Attacus aurata* (South America).—On the 5th of June, 1880, I received from French Guiana a box containing

82 cocoons of this splendid species (the South American *Atlas*), and 18 smaller cocoons of a species called *Bombyx hesperus*. The latter had all been attacked by dipterous parasites. The cocoons of *Bombyx hesperus* are similar in shape and size to those of *Cynthia* (the *ailanthus* silkworm), but they are of a much darker colour. The moths of *Attacus aurota*, of a rich and silky brown, with a triangular window on each wing, are smaller than most of the various races of *Attacus atlas*. The *Aurota* cocoons, of a brilliant golden or silvery silk, are open at one end, and similar in shape to those of *Atlas*. A certain number of the *Aurota* moths had emerged during the voyage, but the remaining live cocoons were in good condition, and produced from the 12th of June to the 19th of August, splendid and perfect moths, which unfortunately refused to pair, the weather being too cold for this equatorial species. On the evening of the 2nd and 3rd of July, the weather being then very cold, a fire was lighted in a large room in which I had a number of cages containing *Aurota*, *Mytilia*, *Selene*, and other moths, but all to no purpose for these three species. At the "Société d'Acclimatation," in Paris, they also failed to obtain pairings from the *Aurota* moths which had emerged from the cocoons I had sent to the secretary of that society.

*Attacus aurota* is found in Brazil, and, very likely, all over equatorial America. Various names are given to different races of *Aurota*, as if they were distinct species. *Attacus speculifer*, found in Brazil, is so much like the true type *Aurota*, that it seems but a variety, if it be even a variety. My own *Aurota* (Guiana race) is rather more like *Speculifer* than the one given as the true *Aurota*. All three, in my opinion, are one and the same species. This multiplicity of names is sometimes bewildering. At the British Museum, for instance, among the Indian species of the genus *Actias*, we find *Actias manas* and *Actias leto*, side by side, it is true. Now these, according to an experienced American entomologist, Herman Strecker, are the same species: *leto* is the name given to the male, *manas* that given to the female. The male is blotched all over with reddish brown, the female is plain green, at least such as I remember to have seen.

The *Aurota* I received has, every year, six generations in French Guiana. Such is the effect of equatorial heat on these insects, whose life is as ephemeral as it is active. How different from insects found in cold countries, which sometimes require three years to reach the perfect state! I have seen cocoons of Indian species, such as *Mytilia* and *Selene*, hibernate twice, and even three times, under the influence of the English climate.

To conclude this notice on *Aurota*, I will translate and quote a few passages from my French correspondent's letters:—"In our French Guiana we have five distinct species of silkworms, but I only have time to rear two, which I do on a hedge in my garden. Our silk-producing larvæ, have regular, pacific habits, which make the rearing easy and attractive. The *Aurota* moths emerge one month after the formation of the cocoon; the pairings here take place in the open field, and the females lay over 600 eggs each; eight days after the larvæ hatch, and in 20 days the cocoon is formed. *Bombyx hesperus* forms its cocoon 15 days after the hatching of the larvæ, and the same operations are renewed every 60 days for *Aurota*, and every 52 days for *Hesperus*. We can therefore produce six crops of cocoons every year, and these crops would have no other limit but the extent of the plantations, the foliage of which is renewed twice a year. So, you may think, how inexhaustible would be such a production of silk, if a European company seriously took this industry in hand. *Bombyx hesperus* and *Attacus aurota* live on the same trees, and both will live, I think, on the *Ailanthus*, *Aurota* lives here also on the orange tree, and on the *Eucalyptus*."

*Attacus atlas*.—In 1879, Mr. P. H. Gosse, F.R.S., of Turquay, published a long and interesting memoir on

*Attacus atlas*, in which a very minute description is given of the egg, the larva in its six ages, of the cocoon and pupa. Herr L. Hueemannberg, in Hanover, has also written a memoir which has appeared in the "Isis" of Berlin 19th, and 23rd of September, 1880.

In one of my reports on silk producers, I state that, in the year 1878, I had a quantity of live of *Attacus atlas*, but the moths having come to emerge in the middle of July, when I was just starting for Paris, I was unable to rear this species. In 1879, I had no cocoons nor ova of *Atlas*, but a French correspondent sent me sixty-five the middle of August. The season being then advanced to give me any chance of rearing here, I sent the ova to two correspondents on the Continent, keeping only twelve, to see when they would hatch, and how long they would live in glass. Both my correspondents failed to obtain satisfactory results. One stated that the ova hatched, the other wrote to me that half of the ova did not hatch, and that the larvæ obtained had a very short time.

With my twelve ova, I obtained five larvæ hatched on August 22nd. Three died in first stage, but the other two, strong and healthy, in splendid condition on the 6th November, were sent for preservation. The weather here was very cold, the foliage might have failed at any time, and the larvæ were too far from the spinning to give any chance of obtaining cocoons; they were in the fifth stage from the 5th of October (32 days) showed no sign of entering into their last stage, to passing into the sixth and last stage. They fed on a superior species of the common (*Berberis vulgaris*), with large thick foliage. I found the best for them. The different stages place as follows:—First stage commenced on August, the second on the 2nd of September, on the 10th of September, the fourth on the 11th of September, the fifth on the 6th of October.

I were five days in sleep before passing into the stage in which they remained as above stated—32 days. I bred in 1878 by Major Lendy, of Sunbury-on-Thames, were only one month from the time of hatching to the formation of the cocoon, but they were in a healthy condition.

The larva of *Atlas*, when hatched, is black, long, white, soft spines. In the subsequent stages the larva appears almost entirely white; this is white powder, which covers not only the tubercles but the greater part of the body, thus rendering the dissection of the larva rather difficult. In the second stage, the colour seemed orange on the head and the body from which no farina was excreted. The larva of *Attacus cynthia* (*ailanthus* silkworm) is covered—but not so thickly—with a white farina in the last stages. On removing the powder, the silkworm is green. Having only two *atlas* larvæ, I did not remove the powder, to see their colour when they were free from it. In the case with other species, there are six rows of spines on the larva, the two rows on the top being the longest; the two lateral rows are very short and almost filiform. The farina on the fourth stage is so thick that they look as if covered with it. In the fifth stage, the larva seemed of a greenish blue, the tips of the spines blue; the anal ring is blue, with small black spots, has on it an orange-red ring. This is a very short and incomplete description of the *atlas* larva, but a complete description is found in Mr. P. H. Gosse's "Memoir on the *Atlas* Moth of Asia." From a letter just received from Mr. P. H. Gosse, I hear that, in 1880, Mr. P. H. Gosse had a success in the rearing of *atlas* larvæ, from ova in June, the result being a number of fine cocoons.

*Attacus Pernyi* (North China).—This most beautiful silkmoth, now thoroughly acclimatized

is double-brooded, has been extensively reared in the United States of North America, during the year on live cocoons I sent to various parts. A student in Illinois, writes that it was double-brooded, and that he found some of the worms had left oak trees, the foliage of which had been eaten and tough in consequence of the hot, dry weather, feeding on hawthorn bushes, growing close to oak trees. Other *Pernyi* larvae were found on roses in a garden, where they reached an enormous number. In France some were reared successfully. According to a statement of my Spanish correspondent, *Pernyi* is essentially an oak feeder, which hibernates after a time, if fed on other trees than

(To be continued.)

## HOWA' OR "MAHWAH," AN INDIAN FOOD-TREE.

By C. G. Warnford Lock.

problem of ensuring a sufficient food supply for millions, cannot yet be said to be satisfactorily solved, though much has been done to avert future famine. Some remarks upon the *Singhara* nut, a highly nutritious article of diet among numbers of the natives of India, appeared in the *Journal* of January 31st, 1879 (vol. xxvii., p. 174). An equally deserving article of diet is the produce of the *Howa* tree.

*Howa*, which is spelt by Europeans in at least two different ways, is applied, it would seem, to *Bassia latifolia*, the most important species, to *B. longifolia* and *B. butyrosea*, whose fruits are edible. The singularity of the genus consists in the fact that, besides offering eatable fruits, their enormous corollas are largely employed for the purpose, and in point of fact, constitute a staple, times almost the only, article of diet available to the poorer classes of Indian natives during several months of each year. *Bassia latifolia* is abundant in the Central India, and is cultivated in many districts.

At the end of February or the beginning of March the crop of flowers approaches ripeness, the corollas becoming fleshy and turbid with secreted juices, which loosen their adhesion to the calyx, and fall to the ground in a snowy shower. The duty of collecting the blossoms is chiefly performed by women and children; at dawn, they may be seen leaving their houses with baskets, and a supply of water for the purpose. Before the crop has begun to fall, they take pains to burn away the grass and leaves at the base of the trees, so that none of the blossoms may be lost when they fall. The gleaners generally remain under the trees all day, alternately collecting the crop and resting, and the male members of the family visit once or twice during the day, in order to carry off what has been collected. At night, bears, deer, and other animals visit the trees, to take their share of the crop.

At early morning and late evening, the less numerous trees, on the borders of the jungles, attract the jungle-fowl and pea-fowl. Cattle are also attracted to the flowers, and cows' milk has in consequence of this season, a strong flavour of *Howa*.

It happens that the collectors come a considerable distance, in which case they erect, with the branches of a tree (*Shorea robusta*), a temporary encampment in which they live until all the crop is gathered. The roof of each of these huts, a piece of ground is smoothed and hard, for the purpose of spreading the flowers to dry in the sun. When perfectly dry, they have a reddish-brown colour, and are reduced to a quarter their original size, and half their weight. It is a custom with some of the natives to spread the flowers out to dry, to pull off the minute foliaceous lobes which crown the

fleshy corolla. It is very difficult to obtain any trustworthy statements as to the yield of the trees. A first-class tree, it has been said, will continue to shed its blossoms for 15 days, at the rate of 120 lb. a day; but this estimate is probably double what it ought to be. The rent of trees varies with their abundance in the district, the quality of the preceding rice harvest, and various other circumstances bearing upon demand and supply. The extreme prices ascertained by Mr. V. Ball, of the Geological Survey, to have been paid for permission to collect, in various places, were 2d. and 4s. The saved crop varies equally in price, the extremes being 120 lb. and 480 lb. for a rupee (2s.); but when, as is most frequently the case, the exchange is made in kind, the merchants give only a small quantity of salt, and 6 to 8 lb. of rice, for the maund (80 lb.) of *Howa*. During the famine in Mambhum, a rupee would purchase only about 24 lb.

Some authorities state that two maunds of *Howa* will furnish a month's food to a family of two parents and three children. It is, however, seldom eaten alone, being mixed with the seeds of the *adi* tree (*Shorea robusta*), or with the leaves of jungle plants; sometimes a small quantity of rice is added. When fresh, *Howa* has a sweet taste, with an odour somewhat suggestive of mice; when dried, it presents some resemblance to inferior kinds of figs. Cooking renders it rapid, and utterly devoid of flavour. On distillation, the newly-dried flowers yield a highly intoxicating spirit, called *daru*, which is generally diluted with five to ten times its bulk of water, and is then sold at the rate of about 1d. a quart. Its odour is most offensive to Europeans, but British soldiers have been known to secure intoxication by drinking it with held noses. By careful distillation, it is possible to get rid of the essential oil which causes the unpleasantness. As much as six gallons of proof spirit have been got from one cwt. of the flowers. The rectified spirit, when placed in oak casks, takes a yellowish colour, and is preferred to high-class Irish whisky. Analysis shows it to be wholesome. From the seeds, is expressed a kind of oil, which is used for cooking purposes, for admixture with ghee (clarified butter), and for lighting and soap-making.

The tree thrives in poor stony ground, and might, therefore, be cultivated on land not available for other crops. Though the natives protect such trees as exist, they do not seem to take any steps to increase the number. The yield of flowers is proverbially regular from year to year. When dried, they will keep for almost any length of time. The large proportion of sugar (50 per cent.) contained in them has attracted the attention of agriculturists in this country, who see in them a valuable cattle food; and Messrs. T. Christy and Co., of Fenchurch-street, are already importing them for that purpose.

## DRY FOGS.

Mr. John Aitken, of Darroch, Falkirk, has made a large number of additional experiments on the formation of fogs since the reading of his paper on "Dust, Fogs, and Clouds" before the Royal Society of Edinburgh, in December last. He then showed that particles of watery vapour do not combine with each other to form a cloud-particle, but that the vapour must have some solid or liquid body on which to condense. Vapour in pure air, therefore, remains uncondensed or super-saturated, while dust-particles, in ordinary air, form the nuclei on which the vapour condenses and forms fogs or cloud-particles. The main conclusion which the author drew from his original experiments was that, "if there was no dust, there would be no fogs, no clouds, no mists, and probably no rain, and that the super-saturated air would convert every object on the surface of the earth into a condenser on which it would deposit." During the present month, he read a paper, illustrated by experiments, before the

Philosophical Society of Glasgow, on "Fogs and Atmospheric Dust," and in the following week he communicated a paper on "Dry Fogs" to the Royal Society of Edinburgh.

From experiments which the author had made, he had drawn certain conclusions, which were thus summed up:—1. That as regards quality and foggy condensation, there was dust and dust. Some kinds of dust had the power of determining condensation in an atmosphere which was not saturated air; and from other experiments it was probable that some degree of supersaturation was necessary before some other kinds of dust were active. In highly supersaturated air all kinds of dust would form nuclei and determine cloudy condensation, but in unsaturated air only some kinds were active. 2. That dry fogs might be produced by some form of dust in the air, such as sodic chloride (common salt), thus condensing the aqueous vapour in the air which was not saturated. 3. This condensing power or attraction which some kinds of dust had for aqueous vapour explained why our breath and condensed steam dissolved even in foggy weather. 4. That as the products of combustion of sulphur determined the condensation of water vapour in unsaturated air, and gave rise to a very fine-textured dry fog, they were probably one of the chief causes of our town fogs, as they had a much greater condensing power than the products of the combustion of coal. It was not claimed that Mr. Aitken's experiments proved that dry fogs in the country were produced by salt dust. The experiments only proved that salt dust could produce a dry fog. In a note appended to his paper, Mr. Aitken added that since making the experiments which had been described, the fog-producing powers of the products of highly heated chloride of magnesium had been tested, and were found to possess a much greater fog-producing power than any other substances with which he had experimented.

### GOLD MINING IN JAPAN.

The Vice-Consul at the port of Niigata, in a recent visit to the gold mines, which are situated at Shimo Aikawa, on the upper slopes of a valley extending down to the shore through the town of Aikawa, states that these mines were first discovered in the year 1613, in the time of Iyeyasu, and have been steadily, though slowly, worked by manual labour till 1869, when the Government determined upon applying the foreign method of mining. Machinery was constructed, and in 1872 was in full working order. Three mines are now being worked—those of Ogiri, Torigoi (a quarter of a mile distant from Ogiri on higher ground), and Aoban. Gold and silver are found in all three, but copper prevails in the first two. Torigoi and Ogiri are imperfectly connected by a gallery, 3,000 feet in length, and a tramway between them is shortly to be laid down. The main shaft is sunk to a depth of about 600 feet, and is situated between the three. As the ore is brought up from the mines through the shafts, it is carried in trucks to sheds, where it is picked by women and classified into four kinds, thence it is conveyed on women's backs to the works, at the rate of 23 cents a ton. A tramway originally connected the mines and the works, but it was partially destroyed by a storm some years ago and has never been repaired. A new road for tramway and bridges, however, is in course of construction. First-class ore generally contains from 50 to 2,000 yen worth of gold, silver, and copper per ton. This ore is crushed, reduced to powder by the stamps, and ground up with mercury into an amalgam (the latter process taking eight hours). This amalgam is distilled and afterwards made into gold and silver ingots. The tailing or refuse parts of the amalgam still contains some metal, to the value of 15 to 20 yen per ton, and is sent to the concentrating tables, where the

gold, silver, and copper are concentrated. Concentrations are afterwards sent to the smelti where the ore is reduced to crude black copper action of heat. After the sulphur has been by calcination, the crude mass is melted in flasks with the addition of lead. The lead sinks to the bottom of the furnace with the gold and silver, and is left behind. The smelting process is repeated four times. The lead is collected into a mass of 20 tons cupelled by German furnaces, and lapses of 50 to 60 hours, bullion is extracted made into ingots of 5 to 700 oz. weight. Smelting is done at Osaka. Second-class ore contains 30 to 50 yen worth of metal per ton, and is smelted by the same process as the first. Fourth-class ore are first crushed, made fine stamps, and subsequently concentrated by the stamps. The concentrations are then reduced by smelted amount of gold and silver produced in the year amounted respectively to 2,195, and 91,713 ounces. Adachi, the superintendent of the mines, states total loss to the Government in working the mines a period of ten years, ending 1879, has been 2,195 yen (about £50,026). This amount, however, Adachi hopes to reduce in a few years. He proposes to erect a new steam-engine of 50 horse-power, and 6 amalgamating pans, and to make other improvements, the total cost of which he estimates at 17,291 yen (£17,291). The annual production is estimated to be about 420,000 yen (£87,500), and the expenses 300,000 yen (62,500). The persons employed in the mines number 1,080, including 120 women picking. Miners working eight hours a day receive 24 cents, and the average wages of miners per six months, has been 18 sen 3 rin (about 18 pence). Women are employed for carrying ore, and for the workshops. Skilled workmen receive 24 sen per day of 12 hours, while in Tôkiô men doing similar work receive 40 to 50 cents. Inferior workmen receive 14 sen 7 rin per day. There are 41 overseers, including one superintendent, one foreigner, six engineers, and four clerks. The daily output of ore is about 20 tons, and the quantity is reduced. The total expense of the mines, amounted, in the year 1879, to 21 yen 74 7/8. In the percussion tables about 10 tons of ore are produced in 24 hours, and in the amalgamating tables 9 tons daily. In addition to the mines of Ogiri and Aoban, gold has also been found in small quantities at Takinosawa, about 12 miles from Aikawa, alluvial deposit of the bed of a river, and also at Mikawa.

### CORRESPONDENCE.

#### TRADE PROSPECTS.

In the Society's *Journal* of the 4th inst., of p. 193, Captain Bedford Pim, R.N., a authority in matters nautical, is reported to have said that "owing to the repeal of the Navigation Act of 1849, 80 per cent. of our seamen were foreigners."

In the *Times* of the 7th inst. (p. 8), I read a melancholy heading of "Disasters at Sea." British vessels had been reported wrecked the previous week (one of such vessels having been another 41 years old); that the total number of British and foreign, for the present year more than five weeks old) had been 295; that had been lost, and that the approximate value of property lost had been £5,200,000, including 10 British.

In the *Times* of the 11th inst. (p. 10), also

ing title of "Disasters at Sea." I read that *Veritas* reports, in part of 203 vessels of all (including, however, 16 missing) in December English sailing vessels and 12 English steamers. Cause and effect be discerned to some extent of the foregoing statements? Is there no constant the "Babel of tongues" and national which must exist on board our ships, when four the sailors are other than British (supposing the and learned ex-member for Gravesend to be his assertion), and the loss in 9 or 10 weeks  $93 \div 12 = 127$  British vessels above re- and the loss in about five weeks of four of British property?

80 per cent. of our merchant seamen are now, in the event of a great naval war, could we and reliable supply of British A.B. seamen at of the odd 20 per cent., to fill up, on the complements of men required for the ships Royal Navy, and to man, and to fight, if need rest merchantmen?

hermen, and life boat, and coast guard men be set of fellows, but could they be spared on our shores in the event of such a war? And d our great carrying trade be safely con-

not something rotten in the present state of d are not the enormous losses, as well as the dums paid for marine insurance, really borne me-tax (so to speak) on commodities by the ring British public? Would it not be instruct- turn were made by the Board of Trade of the spectively, of British and foreign sailors on of every British vessel which should be seriously damaged? A SALR'S SON.

### GOLD IN INDIA.

attended the meeting on this paper, held on e 11th instant, I beg to make the following is on the question of labour, raised during the

would, in my opinion, be a mistake to send number of Cornish miners to India, as they a deal of trouble, and do little work. Nor ary to do so, seeing that native Wuddars can l, who are skilled in the use of jumpers and in blasting operations, also in the splitting of ad rocks by hammers or rows of wedges, and quickly understand any system that may be r carrying out works.

only Europeans required would be men suit- ave the supervision of the work, with a fier to organise and direct.

inion is formed from my experience in India years 1866-7-8, when I had chief charge of ction of the railway works between Koolburga ore, about 200 miles north of Mysore.

operations were commenced, not more than forty men could be obtained, and these were ned to the kind of work, but within a year, from eight to nine thousand men were got om various districts, so that no difficulty as eed be apprehended.

JOHN ROBINSON, Civil Engineer.

East Grinstead Railway,  
Ineer's-office, Kingscote, East Grinstead,  
Feb. 14th, 1881.

### PREVENTION OF FLOODS.

ng the face of the country, one is struck with r, tortuous character of the water-courses streams in many places, also, weed-grown with gravel. Much good might be effected

on every farm if these ditches, water-courses, gulleys, &c., were, as far as possible, straightened; but, at all events, carefully dredged, widened, deepened, and (where necessary) embanked. It would be necessary to resort to dredging at intervals of about four years, even when the work was well done at first; in fact, constant attention would be needed as a consequence of the winter's frost, the spring freshet, and the summer's growth, so as to maintain these arteries in a fit condition to act as water carriers. It may be as well to add that, if this were done, it would be necessary to make arrangements to secure effective irrigation, and also a storage of water to provide for seasons of drought.

It may be said that this work would be both arduous and costly. Unquestionably; but, at present, the loss to the country through the desolating waters amounts, in one or the other of the ways I have mentioned, to hundreds of thousands of pounds annually.

The best plan would seem to be, that the farmers of a certain district should associate themselves together, employ such machinery, and such a number of hands, under skilled and experienced management, as would ensure the effectual carrying out of the work.

Doubtless, if this is really to be attempted, the landlords must assist. The farming interest is so heavily weighted, that it cannot pay even a moiety of the cost. The importance of the subject must be my excuse for bringing it, at this time, under the notice of members of our Society.

JAMES O. BEVAN, Assoc. Inst. C.E., &c.

72, Beaufort-road, Edgbaston, Birmingham,  
February 19th, 1881.

### GENERAL NOTES.

**Telephones in India.**—The Government Telegraphs Department in Calcutta obtained in November last, a sample supply of some thirty of the loud-speaking telephones of the Gower-Bell Company for experimental trials, and it is reported that the results have given so much satisfaction that the company has now received by telegraph an order for a large number of its instruments. If, says the *Engineer*, this may be taken in conjunction with the recently announced refusal of the Government of India to sanction the setting up of telephonic exchanges on the part of private speculators, it would seem to indicate a resolve on the part of the executive itself to supply the Indian public with what will soon be found to be an indispensable aid to the business and pleasure of life in India.

### MEETINGS OF THE SOCIETY.

#### ADJOURNED MEETING.

Friday evening, at eight o'clock:—

FEBRUARY 25.—Discussion on Mr. Sedley Taylor's paper on "The Participation of Labour in the Profits of Enterprise." W. H. HALL will preside.

#### ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

MARCH 2.—"Lighthouse Characteristics." By Sir WILLIAM THOMSON, LL.D., F.R.S. F. J. BRAEMWELL, F.R.S., Chairman of Council, will preside.

MARCH 9.—"Ascents of Chimborazo and Cotopaxi, in 1880." By EDWARD WHYMPER.

MARCH 16.—"The Compound Air-Engine." By Col. F. BRAEMONT, R.E.

MARCH 23.—"The Increasing Number of Deaths from Explosions, with an Examination of the Causes." By CORNELIUS WALFORD.

MARCH 30.—"Recent Advances in Electric Lighting." By W. H. PREECE.

## FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

MARCH 1.—"The Languages of Africa." By ROBERT N. CUST.

MARCH 15.—"Diamond Fields of South Africa." By R. W. MURRAY.

APRIL 5.—"Trade Relations between Great Britain and her Dependencies." By WILLIAM WESTGARTH.

## APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

MARCH 24.—"The Future Development of Electrical Appliances." By Prof. JOHN FERRY.

The meeting previously announced for April 7 will be held on May 12.

## INDIAN SECTION.

Friday evenings, at eight o'clock:—

MARCH 4.—"The Results of British Rule in India." By J. M. MACLEAN. Sir DAVID WEDDERBURN, Bart., M.P., F.G.S., will preside.

MARCH 25.—"The Tenure and Cultivation of Land in India." By Sir GEORGE CAMPBELL, K.C.S.I., M.P.  
MAY 13.—"Burmah." By General Sir ARTHUR PHAYRE, G.C.M.G., K.C.S.I., C.B.

Members are requested to notice that it may be necessary to make alterations in the dates of the above papers.

## CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Third Course will be on "The Scientific Principles involved in Electric Lighting," by Prof. W. G. ADAMS, F.R.S. Four Lectures.

*Syllabus of the Course.*

## LECTURE I.—MARCH 7.

The production, regulation, and measurement of electric currents.

## LECTURE II.—MARCH 14.

The laws of the mutual induction of currents and magnets. Efficiency of magneto- and dynamo-electric machines.

## LECTURE III.—MARCH 21.

Use of magneto- and dynamo-electric machines for electric lighting. Heating effects of the current. Electric lighting by means of the arc.

## LECTURE IV.—MARCH 28.

Subdivisions of the electric current. Incandescent lamps. Luminous effects of electric currents in a vacuum, and in various gases.

The Fourth Course will be on "The Art of Lace-making," by ALAN S. COLE. Three Lectures.

April 25; May 2, 9.

The Fifth Course will be on "Colour Blindness and its Influence upon Various Industries," by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

May 16, 23, 30.

## MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 28TH....Royal Geographical, University of London, Burlington-gardens, W., 8½ p.m. Sir Richard Temple, "The Lake Region of Sikkim, on the Frontier of Tibet." British Architects, 3, Conduit-street, W., 8 p.m. Discussion on "The Existing Law of Light and Air."

Institute of Actuaries, The Quadrangle, E.W.C., 7 p.m. Mr. G. R. Hardy, "The observed amongst the Various Classes of Life in the British Empire Mutual Assurance Co. Medical, 11, Chandos-street, W., 8½ p.m. London Institution, Finsbury-circus, E.C., Justin McCarthy, M.P., "Ireland."

TUESDAY, MARCH 1ST...SOCIETY OF ARTS. Adelphi, W.C., 8 p.m. (Foreign and Colonial) Mr. Robert N. Cust, "The Languages of Royal Institution, Albemarle-street, W., 8 p.m. E. A. Schaffer, "The Blood." (Lecture I) Medical and Surgical, 53, Berners-street, W., 8½ p.m. Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on "The Limiting Dimensions of Girder Bridges permitting, 2. Sir William Thomson, "Tidal Harmonic Analysis, and Tide Prediction." 3. Conduit-street, 1. Rev. A. Lowry, "A Few Notices in Asiatic Writings on the Sagacity and Habits of the Elephant." 2. Eberhard Schrader, "Abydenus and Daniel." Zoological, 11, Hanover-square, W., 8½ p.m. F. Moore, "Descriptions of New Genera of Asiatic Nocturnal Lepidoptera." 2. Westwood, "Observations on Two Species of Butterflies, *Papilio castor* and *P. pollux*. Collett, "Halicarnus gryphus and its Breeding Islands, off Trondjem's Fiord, in Norway."

WEDNESDAY, MARCH 2ND...SOCIETY OF ARTS. Adelphi, W.C., 8 p.m. Sir William Thomson, "House Characteristics." Entomological, 11, Chandos-street, W., 7 p.m. Pharmaceutical, 17, Bloomsbury-square, W., 8 p.m. 1. Mr. E. M. Holmes, "Vote on Jafer." 2. Mr. E. M. Holmes and W. Elborne, "Drugs from Sootia." Archaeological Association, 32, Sackville-street, Mr. J. Romilly Allen, "The Saxon Cross in Lancashire." Obstetrical, 53, Berners-street, Oxford-street, W., 8 p.m.

THURSDAY, MARCH 3RD...Royal, Burlington-house, 1. Antiquaries, Burlington-house, W., 8½ p.m. Linnean, Burlington-house, W., 8 p.m. Shattock, "Reparative Processes in Plant Tissue." 2. Mr. J. H. Bell, "The Apparent Retention of Plate by a Young *Echinometra*." 3. Clarke, "Arnebia and Macrostromia." 4. Watson, "Pleuronotomids of Challenger Expedition." Chemical, Burlington-house, W., 8 p.m. Hatton, "The Action of Bacteria on Vegetable Matter." 2. Dr. C. M. Tidy, "The Oxidation of Organic Matter in Running Water." 3. Dr. F. R. Japp, "The Action of Aldehydes on Iodoquinone in presence of Ammonia." (See 4. Dr. Japp and Mr. N. H. J. Miller, "Benzole Acid on Naphthaquinone." (Preliminary London Institution, Finsbury-circus, E.C., J. G. Wood, "The Inside of an Insect." South London Photographic (at the H. Society of Arts), 7½ p.m. Royal Institution, Albemarle-street, W., William Houghton, "The Picture Origin of Form Characters." (Lecture I.) Pathological, 53, Berners-street, Oxford-street, Civil and Mechanical Engineers, 7, Westminster S.W., 7 p.m. Mr. J. B. Walton, "Steam versus Heavy Works." Archaeological Institute, 16, New Burlington, 4 p.m.

FRIDAY, MARCH 4TH...SOCIETY OF ARTS, John-street, W.C., 8 p.m. Mr. J. M. Maclean, "The British Rule in India." Royal United Service Institution, Whitehall, Sir William Thomson, "His New Navigational Machine and Depth Gauge." Royal Institution, Albemarle-street, W., William Thomson, "Elasticity viewed as a mode of motion." Geologists' Association, University College, 1. Professor T. G. Bonney, "Remarks on the Classification of Rocks." 2. Professor J. A. H. H. "A New Theory of the Formation of the British Isles." 3. Notes on the Microscopic Structure of Basalt of Swallow Cliff and Uphill." Philological, University College, W.C., 8 p.m. Brandreth, "Grammatical Gender."

SATURDAY, MARCH 5TH...Ladies' Sanitary Association of the Society of Arts, 54 p.m. Dr. J. H. H. "Domestic Sanitation or Health and Hygiene." Royal Institution, Albemarle-street, W., Stuart Poole, "Ancient Egypt in its Civilisation." (Lecture III.)

## L OF THE SOCIETY OF ARTS.

No. 1,476. Vol. XXIX.

FRIDAY, MARCH 4, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## HYMPER'S PAPER ON CHIMBORAZO.

ordinary meeting, on Wednesday, 9th  
r. Edward Whympers will give an account  
nt ascents of Chimborazo and Cotopaxi.  
to accommodate the large number of  
who have applied for tickets, this  
will be held, by permission of the  
he Committee of Council on Education,  
sture Theatre of the South Kensington  
Admission will be by the West Entrance  
useum in Exhibition-road. It is hoped  
rrangement will be found convenient to  
ars. Though every effort was made, it  
impossible to obtain a room of sufficient  
he Society's House.

eting will commence at Eight o'clock.  
n at Half-past Seven. About twenty  
ill remain for distribution, and one  
be supplied to Members who apply  
number is exhausted.

on can be admitted without a Ticket.

By Order,

H. TRUEMAN WOOD,  
*Secretary.*

## STREET ACCIDENTS.

meeting of the Council on Monday, 28th  
an application from the Society for  
; Street Accidents was considered, and  
ing gentlemen were appointed a Com-  
meet a deputation from the Committee  
ociety, viz.:—Sir Rutherford Alcock,  
r. G. C. T. Bartley, Mr. Andrew Cassels,

Sir Henry Cole, K.C.B., Sir Philip Cunliffe-Owen, K.C.M.G., C.B., C.I.E., with the Chairman of the Council (Mr. F. J. Bramwell, F.R.S.). The Committee of the Street Accidents Society appointed to confer with the members of Council are:—Lord Dorchester, Viscount Templeton, the Rev. W. Rogers, Mr. Brown, and Dr. Goodsall.

## UNION OF INSTITUTIONS.

The following Institution has been received into the Union since the last announcement:—

North London High School for Boys, Castle-house, Mildmay-grove, N.

## APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday, Feb. 24, 1881; Captain Sir GEORGE NARES, R.N., K.C.B., F.R.S., in the chair. The paper read was "Deep Sea Investigation, and the Apparatus employed in it," by J. J. Buchanan, F.R.S.E., F.R.S. This will be printed in the next number of the *Journal*.

## PROCEEDINGS OF THE SOCIETY.

## ADJOURNED ORDINARY MEETING.

Friday, February 25th, 1881; W. H. HALL in the chair.

The discussion on Mr. Sedley Taylor's paper on "The Participation of Labour in the Profits of Enterprise," adjourned from the 16th ult., was resumed.

Mr. George Shipton said he should like to refer in a few words to the remarks of the Chairman in reference to English trades unions. He understood him to say that, probably, we had not been able to see our way to such a means of reconciling the interests of employers and employed in this country as had been arrived at on the Continent, in consequence of the hostility of English trade societies. He was sure the Chairman would be the last knowingly to inflict such injustice on English trade societies, and he could assure him that members of the trades societies, instead of being hostile to any conciliatory offer, were always the first to make it. He could say a great deal on the other side, of men who had entered into negotiations and signed contracts that there should be no alteration of time or of wages without three or six months' notice, and he had known employers, in the face of an agreement like that, signed by both sides, scatter the whole thing to the winds without the least notice, and insist on a reduction of wages, and lock the men out if they refused. There was a case of the kind in Bristol at that very moment. However, he had no desire to use words which would increase any bitterness which might exist between employers and employed. They were met for a different purpose, that of endeavouring to recon-

ells the interests of both parties as far as possible. The subject had been somewhat departed from last week in the discussion, which touched on the question of good work and bad work, piece work and day work. This would form a very fitting subject for discussion by itself, but he would prefer pointing out what seemed to him defects in the various schemes brought forward by Mr. Taylor. To begin with, he took exception to one point, which, unless it were got over, would prevent English working men from taking an interest in the scheme, and that was to say that the participation should only take place in the profits to be created by the exertions of the men. He certainly thought that if workmen, by their own perseverance, skill, and care, made profits which the employer had not contributed to, those profits rightfully belonged to the men, and surely the employer would not be so immoral as to participate in profits which he had not been instrumental in creating. If the participation were only to come out of new profits, they had to thank the employer for nothing. He held it should be a participation in the general profits derived from the joint energies of those employed in the particular house, or calling. The next best scheme was very much after the fashion of the one adopted by Mr. Bord. He should advocate immediate cash payments of profits to workmen, and not a deferred advantage, though possibly there might be some reason why an agreement to defer the payments should not be made. It might be said that if the workmen suddenly enjoyed a degree of prosperity they were not used to, they would squander the money, but he had yet to learn that that did not apply to other classes as well. Why should a special moral restriction be applied to workmen, which was not applied to all classes? The Rev. Mr. Blackley had put forward a national scheme of insurance, which certainly had the merit of compelling all classes to contribute, without exception. What he objected to in Mr. Bord's plan was, that he wrote off 10 per cent per annum on the capital invested, and then took half the profits remaining, the other half being divided proportionately amongst the workmen who had contributed towards those profits. He thought 10 per cent was an excessive price to charge as interest upon capital sunk in a business, and that 6 per cent, he held that was the maximum. If they wrote off 5 per cent, he held that all the profits derived from the joint energies of those engaged in the firm should be divided proportionately to their wages, amongst employers and managers, giving to the employers their extra share as managers, and so on, but if they were going to make themselves no secure, first by having 10 per cent. on the capital, and then taking half the profits, there was very little left for the workmen. It seemed to be the idea that all these things must come from the workmen's side, and nothing from the employers. Otherwise, inasmuch as Mr. Bord's plan was the best, inasmuch as there was an immediate payment of profits. The proposition of Mr. De Courcy was simply an utter piece of selfishness, and he should be sorry to see it applied in his position of Mr. De Courcy was employed in the firm 25 years, and then it was not paid to them at all, but invested in the house, or in Government funds, and practically the men received no direct advantage. He was one who did not approve of postponing every advantage from his labour until he was dead and gone. Mr. De Courcy's own language showed the scheme to be an utterly selfish one, because he referred particularly to its influence in making the employed work long hours in place of paupers hands being engaged. Now, if they only looked at the fact that in England there were a million of paupers to keep, and that one in ten of the population died a miserable or a pauper, it was absurd to put up a scheme like this to shorten the hours of labour, and to shorten the hours of workmen might

come and take part in such discussions as the present. English workmen were ever to hold their own in such a degraded and ignorant race. If they had not time, how could they improve themselves, in character and their own conscience. He should therefore deprecate any system which would tend to produce a deterioration of the workman, and shut out those who had already a position in the firm. Mr. Bord's plan was too paternal. He would rather see a man entrusted with his own money, even if he made mistakes at first, because it would lead the way to a better state of things hereafter, and the freedom would have been much more valuable than the Government. English workmen would never be induced to go into any scheme of that kind. About 1878, payment were deferred. He could give a striking instance of this. About 1878, Wingate and Co., ship-builders, at Glasgow, in their establishment, an insurance and a fund, to which the workmen were compelled to subscribe. This was retained by the firm, and was positioned in the name of the firm. Some time after went into liquidation, seized on the money, and distributed it amongst the creditors as part of the assets. That the workmen, although it had been done from their wages, lost every farthing of it. The system which would hand over to the employer profits to keep for the workmen would be highly satisfactory. If the sums were held in trust for at all, it should be done by some responsible body some one agreed upon by both. As far as had time to study the plan of the Leclaire, that was the best as a compromise, there the workmen's counsels were brought into operation with the employer. The emphasis his proper position as administrator of the firm, giving to it all the force of his individual character at the same time allowing his workpeople to share in the whole profits. There was only one thing he should like to have cleared up. He had to be employed for six months before he participated in the profits. Now, in times of crisis were many workmen called in for three or four months who contributed to the prosperity of the firm, could not see why they should be shut out from participating, to some reasonable extent, in the profits. No more than 5 per cent. was accumulated by the extra work done during working hours, and the extra profit developed amongst the men, and not extended to all workmen, and he did not intend that the system should solely through any "nigger-driving" the workmen were to work the death in order to live, which was a physical deterioration. It should be agreed with Mr. Taylor's position of his remarks. If there were as kind, one thing was absolutely true, that the English employers should not be arrogant, and no longer remain in council. At present, no men in their carriages, and knew no agents, and managers, but never came in contact with the vicissitudes of labour and the present time that had been but if there were a change

glad to carry out such a scheme as that pro-

William Botly could not quite agree with the remarks of Mr. Shipton. He rather understood 10 per cent. would be 5 per cent. on the capital in the business, and that the other 5 per cent. be for the maintenance of the manager. As to the importance of dividing a portion of the among the labourers, there should be a consensus of opinion, and he thought, on the general idea of the paper, they would be all agreed. In fact which they all professed to be the rule of the, they were told not to muzzle the ox that ate the corn, and that the labourer was of his hire. Anyone at all acquainted with nature, agriculture, or commerce, found that it was in the interest of the employer to do his duty to the men, by giving him a sufficient wage for his day's work which should allow him to provide for old age. It should all do what they could to encourage the principle now brought forward would, might encourage that, and also the straightforwardness which they all desired to see in the workmen. The paper had given proof of the beneficial participation in profits in France; and notwithstanding some difference in the habits of the French and English, he did not see why the same should not be adopted here. The remarkable result of labour, until it was ascertained, of unknown quantity, was quite correct; but the worker might be paid the regular wages of the district, and at the end of the year the profit could be very easily reckoned. That would be equally applicable to agriculture. There were many in England where that was done—as, for instance, on the property of the Speaker of the House of Commons. No doubt, there would be occasions—as, for instance, the year before last, which was the most profitable year ever remembered—when there would be profits. One gentleman said the loss to the farmer, on wheat alone, was five millions; he believed it would be found the loss would be 10 millions; and, of course, in that year the rural labourer would have had no division of the profit at all. He hoped to see the time when, by education and more thrift—which every one could encourage by their own example, whatever their position in life—the position of English workmen would be improved. No one ever rose to eminence without application. This was shown in the case of Moore, the Morrisons, and others. Some might say workmen had not the power of doing so generally he said they had. He knew instances of men who had raised themselves from common labour to be small farmers; but then they made much which the generality did not do—they were not drunkards, but made the most of every trifle.

Another man said he did not come with the intention of arguing, but he thought he was bound to meet the remarks which were made by Mr. Shipton and to employers and workmen. He stated that workmen were always anxious for arbitration, to submit their case for equitable decision, and employers were not so. But look at the present affairs in Lancashire and Yorkshire. In these districts the colliers have struck for higher wages, which employers say they cannot give; and they have a proof of this, to lay their books before any accountant, and to submit the whole dispute to arbitration. According to the papers, that had been

He did not wish to say a word against workmen, but he protested against the entire class of embezzling capitalists being stigmatised as tyrannical and because some had been harsh. Mr. Shipton said more than five per cent. being allowed to

the employer. But take the case of hazardous businesses, such as collieries, in which he was largely interested, and in one of which he was a director. They were liable to explosions and all sorts of accidents. Would any man who had money be satisfied to put it in these hazardous things for five per cent.? It would pay very well in some things. Three per cent. paid in Consols, but 20 per cent. would scarcely be a remunerative return in other occupations, such as mining, where the chances of loss of both capital and interest were very great. Mr. Shipton also stated that the whole of the profits should be divided amongst the workpeople; not that which they made by their own diligence or extra work. But would they divide the losses as well? It was necessary to face this question. They would only give five per cent. interest, and all the additional profits must be divided amongst the men; what about the losses. For various reasons he was in favour of a partial division of profits and superannuation. If a man went into an establishment, such, for instance, as Krupp's Iron Works, and he knew by the rules he would be entitled to superannuation by a certain time, it was a check on the natural tendency of a young man to change, and the consequence was, men would stop in such an establishment, with the result that they went on all through their lives at good wages, with plenty to eat and drink, and everything a man wanted, whereas, if they got the whole of their profits they would probably become rolling stones and ramble about, some would get to high positions, and others would go to the workhouse. He should prefer the middle course, giving the man a share every year of the extra profits, and putting by an equal amount, which he should be paid in case of accident or death. A case had been mentioned of the money put by being seized by creditors, and he believed something of the same sort took place with regard to a co-operative farm, which was carried on successfully for some time in Ireland, but all this could be guarded against if proper arrangements were made in the first place. Then it was said that new men ought to share with the old, but he could not see the justice of that. It was not the case anywhere, that he knew of, that a new man in an establishment got equal wages with an old one, except, perhaps, in a particular shop, where every man went in on the same footing, under special circumstances. He believed the participation plan was the best which could be adopted; and he thought the reason why some efforts of this kind had failed was, that the difficulties were not sufficiently appreciated and provided against. Some men would not care for the system, others, on the contrary, appreciated it. He could understand why Leclaire succeeded, by reading his life. He started as a workman, and gradually built up his establishment, and he could imagine him carefully selecting his men and his foremen; and when he commenced this participating scheme he was surrounded by a set of men whom he knew, and who knew him. The same principle would answer in this country, and it would help to put an end to piece-work, which, in the interest of all concerned, it would be well to get rid of, if possible. He did not see why the plan should not succeed, if it were carried out here with the intelligence which Frenchmen exhibited, but it should not be put in force without preparation. The men should be selected in the first place, and there should be means for getting rid of those whom it did not suit. He had always seen, that if you gave a man an interest in his work it would be done better, and more of it would be done.

Mr. George Howell said Leclaire's system did provide for dividing profits with the very newest comer into the firm, an instance of which was given in Mr. Hall's book on Mr. Sedley Taylor's article, of a man who had worked one day of ten hours, when he received 6 francs and

50 centimes for his wages, and, at the end of the year, he had his proportion of profits just the same as the rest. He thought they had not yet realised the principles laid down in the paper, the central point being that the men contributed nothing in the shape of capital to the firm, but the whole of the capital was got out of profits. He was now using the term capital in the sense of money, not in the widest sense. The principle seemed to be this, that the men, not by working longer hours, but by working the ordinary day and being paid the current wages in the trade, having a chance of participating in the profit, threw an amount of intelligence, and skill, and energy into their work which had not previously existed. He did not think the workmen had anything at all to complain of in that respect. If they were paid the current wages, they realised that for which unions were primarily started, and if by extra energy and skill they could create more profits than the master originally obtained by the ordinary, perhaps slovenly and wasteful work, they were allowed to participate in those extra profits. That was only the first initiatory stage of the scheme, a stage which, to his mind, could be applied easily to almost the entire ramifications of industrial life in this country, and the workmen surely would have nothing to complain of if, after having been paid their just wages, they realised something in the way of profits, the higher the share, the better, of course; in Leclaire's establishment, it amounted to about 15 per cent. It ended in this—and the moral was the grandest part of it—that these workmen became better workmen than the ordinary workmen in the trade, and were not only paid the ordinary wages of the district, but could command higher wages, and were actually paid higher wages, and, in addition to that, still had the bonus. That was the earlier stage of the matter, but it was the other stages taken up by Leclaire which showed up the moral grandeur of the scheme, and he could not believe Englishmen were so far behind Frenchmen that the same could not be done here. He did not think Englishmen were more selfish than Frenchmen, though they might not be quite so free in their speculations. Leclaire's scheme was worked out under the great disadvantage of not being able to meet in public and discuss their plans, and thus lay down the basis upon which to work. The first starting-point seemed to have been his absolutely bringing in some bags of money and dividing the profits—not upon the year he had promised them, but upon the previous year, because the Government had refused permission to hold a meeting. The scheme which, perhaps, caused the greatest amount of discussion was the greater and broader one, in which the men became absolute co-partners—a scheme which, in a certain sense, had been applied in this country, and was still applied in some instances; but, in this particular case, not only were the men paid their full wages, and participated in a certain proportion of profits, but were entitled to all the benefits of the mutual aid society—in its first stage contributed to by the men and by the masters, but ultimately only contributed to by the profits—and the men participated in the first distribution of its funds when the society was dissolved. Subsequently to that, and in all later stages, the capital seemed absolutely to have been created out of the firm, a proportion of it having been set aside, in addition to the wages and the bonus, until the mutual aid society had sufficient funds, or nearly so (the balance being made up by Leclaire himself), to make it a sleeping partner in the concern. When the employers of England, or a large number of them, could once see their way to say to any number of men in their employment that they were prepared to make a similar step to that, his belief was that the workmen, whether unionist or non-unionist, as a rule would jump at it, but the difficulty was the one hinted at by the last speaker with regard to the losses that might be sustained in the course of business. Those losses were

prudently prepared for by Leclaire, as they were by other prudent employers. A man who made 20 per cent. this year, as a celebrated firm did which had been referred to in the course of the debate, and divided the profits among the proprietors, and made no provision by a reserve fund, and then asked the men to help bear the loss when it came, was a very different thing to Leclaire's system. It was not enough to say whether the firm should reserve to themselves 2 per cent. or 10 per cent., seeing that the firm made business and found the capital. No doubt 5 per cent. was beginning to be recognised as much less than a fluctuating per-centage, ranging from 1 per cent. or 20 per cent to nil; and when they provide against these contingencies, it might be found that 5 per cent. would be sufficient. It was just the amount reserved by Leclaire as interest on capital in his business, that given equally to the partners for their share, and to the mutual aid society for its share, although its share of capital was made out of the profits. The question was, was there any insuperable difficulty in the part of English working men to entertain proposals of this kind, should they be made by their employers? He could not conceive for one moment that there was any objection to the scheme being tried anywhere, that any well organised trade union would raise any objection to it. It was altogether outside the power of the unions. He did not mean to say but that a well conducted firm of this description might indirectly interfere with the working of the union, but some of the societies had a very well elaborated scheme of mutual aid, in the shape of a sick fund, an old work fund, and so on, such as was provided for in the mutual aid society of Leclaire, and that might indirectly interfere with indirectly; but, if it were found that this could be done better in some other way, Englishmen would soon agree to the change. But suppose the scheme to go on in the most favourable manner, would be a long time before it would be able to do so with great unions, like that of the engineers', who perhaps, provided more for the sum paid in than any other benefit society. He could see many reasons why workmen should seek these advantages if employers were only willing to concede them, but it was lamentable to him to find that instead of the bonds of union between employers and employed being made closer they were being continually loosened. They began that when they went from the month to the week in hiring, and from the week to the day, and again from the day to the hour, and the system existed now of mere casual contracts. How was it possible for any individual man to have an interest in the welfare and prosperity of a firm when he might be dismissed at a minute's notice? Anything which would give him a permanent and binding interest in the firm would help him in future life in more ways than the mere fact of getting regular wages, because it would have a great moral effect. He was, therefore, in favour of helping forward this movement as far as possible, by discussion and otherwise, until some employer of labour, having something like the general sympathies of Leclaire, would be prepared to try it on a broad basis. With regard to the character of the business in which it was tried, he did not think that house-painting and decorating business in Paris was quite of the precarious kind that it was in this country, and so far, Leclaire had an advantage; but it must be recollected that the painting and decorating business in this country were not limited to those who were connected with jerry builders and field ranging, as it is called. There were great firms in London which kept their men on almost permanently, only discharging them under great and continued pressure. If the scheme could be tried in that particular trade where a man could take upon himself a certain amount of independent action, and yet must co-operate with the whole of the

produce a good result, it could be done in a. It was tried in this country to a greater in many supposed, especially on the system icularly commented upon by Mr. Shipton fered profits; but it sometimes became to compel the owner of a share in the profits to go out of the firm, and take his ith him. He did not know whether he was urate, but he had heard, on good authority, a who had been for 24 or 25 years occupy- poal position in a considerable firm, and who dy in life had participated in the profits to a ent, and also allowed a portion of his salary nuate. Ultimately, some alterations being e the firm, it was suggested to him that he ure from the business; he was willing to do gh he did not like leaving, but said he should ave his money there. He was told, however, y had as much as they knew what to do with, ough it seemed an incredible sum, he was in- on good authority, that the man was paid no \$50,000 as his share. In Leclaire's establish- percent., on the average, was divided for nine d in addition to that the men had £21 each out tual aid fund when it was shared. If they on to a second share in that fund, it seemed t, in the course of the next 15 years, they e shared from £50 to £60 each. He could hat he hoped some employers in this country e their way to bind their men to them ing them a participation in profits, and e making them co-partners in the firm, ne example of that kind would do a great o advance the matter than any amount of

He said he had read Mr. Taylor's paper and ion on the previous occasion, although he was t, and he was strongly of opinion that under ditions labour was entitled to much more ent it generally received out of the profits e. He said this as an employer. Taken , capital now stood as an absolute ruler of exercise, a despotism of the most absolute but he was of opinion that such a system e much longer tolerated. These schemes elieved, honest endeavours to find a remedy t for labour more justice, and he should assist in the proposed society for making the r known. It would be much more difficult, in England than in France, because the re much more suited to co-operation; the ere slow to believe in any idea until it was be an advantage, whilst the French were y any new scheme of equality and frater- th respect to the conditions under which on could and should be attempted, any o try it where the employer did not consider that he had certain moral duties about, would soon, he feared, end in failure. um read a paper at the last Trades Union in which he dealt with the position of , and pointed out that they ought to regard : as discharging a public function, namely, onservators and administrators of human Unless capitalists recognised these moral l obtained the respect, esteem, and trust of men, he could see nothing but failure. Carlyle ash never yet paid one man fully his deserts to and never would. You might commence on in a concern by appealing to the greed and of the employes, and in that way get them to r and amass money, and assist capitalists to e, and this was pretty well as far as Mr. had the matter to be carried, but in his f was a most objectionable way of gaining a f prosperity, even if that could be thus . They must appeal to the great moral power

in man, not to his selfishness and greed. A true work- man did not work honestly and thoroughly because he was paid to do it, but because he felt to do the contrary was despicable and dishonest.

Mr. Pfoundes thought they were overlooking the fact that a great deal had already been done in past years in the direction pointed out by the paper in foreign countries. Twenty-four or twenty-five years ago, efforts were made in this direction in the Australian Colonies, and he wished to point out the necessity of turning attention to what our own countrymen had done, when released from the trammels so much com- plained of, which hampered them at home. There were thousands of the most intelligent of our countrymen living in the colonies and foreign countries, who were actually now competing under most favourable circum- stances with those at home, and the time had come when a question like this should be taken up on a broader basis, so that, admirable as the paper was, he sub- mitted it was not altogether what was required. If they could go abroad and see how their own country- men succeeded there, they might learn some very valuable lessons. The improvement had to come from the men themselves. He had seen English- men, landing in Melbourne, laughed and jeered at as new chums by their own countrymen, who had only been two or three years in the colony; and in the same way in Castle Garden, New York, he had seen them laughed at as gawkies, by those who had only been in that country a year or two. He had seen the same class in the New English States, and in the colonies, showing a wonderful improvement in two or three years; and since his recent return to this country, he had seen the necessity of something more than the merely half-hearted measures which were continually suggested, being brought forward. He did not think it was practicable, in a business point of view, to entirely adopt principles which might, more or less, succeed in foreign countries like France; but an entirely reformed social system would be needed; and that reform must come from below as well as above. While there were these conflicts going on between work- men and employers, and they were constantly quarrel- ling over the shell, other nations were stepping in, and taking the oyster out. Our commerce was falling from our hands, simply from the quarrels of labourers and capitalists. How could they expect a division of the profit which must, in great measure, result from clever, hard-headed men, when they were obliged to go on the market, and speculate in raw material, to keep their hands employed. When he was abroad, some of their own correspondents had sent out goods which were sold at a loss; but they were manufactured simply to keep the mills going. How were profits to be divided in such cases? Would the men stand having a per-centage taken off their paltry wages, in case the head of the firm made a mistake on the market?

The Chairman said there was no intention of taking anything off anyone's wages, the proposal was to add something to them.

Mr. Pfoundes said what he wanted to point out was the necessity of looking to what our countrymen were doing abroad.

Mr. Phillips said his impression was that no system except that of Leclaire was worthy of consideration, because all the others were simply the development of selfishness. They sprang from selfishness in the employer, were calculated to develop selfishness in the workmen, and on the whole, would tend to demoralisa- tion. Leclaire's principle was very simple, and would be immediately applicable not to one occupation only, but wherever people were employed; the only requisite

was to find the employers with an inborn spirit of justice sufficient to induce them to put it in practice. Once you had the principle, others would soon follow and co-operate. The public, who were much interested in the kind of goods they purchased, could assist by giving such establishments their support. Sometimes there was a confusion made between the capitalist and employer. You sometimes heard rich men called captains of industry, but many of them were not captains of industry at all; they were simply owners of capital, who farmed the industry and intelligence of other men. They took six portions out of ten, and gave the workman only four to live upon, while they grew rich on the six parts they had taken. That was the general rule, and it was supported by the principles of the dismal science. To these men it did not matter whether the wages given to the workmen were sufficient to keep body and soul together or not; if they could get a man willing to accept such wages they felt justified in giving them. But that was not a fair portion. If that system continued to prevail, the labouring people throughout the world who now spoke with one sentiment, but different languages, would eventually have those sentiments conveyed in one language, and when they did so speak, it would be with a solidarity that would have power to act. And how would it act? That lay with the capitalists and employers who regulated the legislation of the country. If they sowed wisely they would reap well, but if they sowed the miserable system which now existed, the time would come when they would reap ill. Various points had been raised which hardly bore on the question. With regard to the interest which should accrue to the invested capital, a statement was made with regard to mines, that the capitalist who invested in a mine suffered from explosion and accidents. He always thought the boot was on the other leg. It was not the capitalist who suffered, but the men. If 16 per cent. was a fair per cent. for the capitalist to receive who invested his money, what was a fair percentage for the man who invested his life? Much stress had been laid on the participation of profits *versus* participation of loss, but he believed the workman was just as fair and intelligent as the capitalist, and if you gave the workman a fair share of the profits, he would be quite willing to take his fair share of the loss. He would not deal with many of the side issues which had been raised, but with regard to piece-work and waste of material, he might say that he had frequently had charge of work, and while in that position had an opportunity of seeing how it was done, and how material was used. He had seldom cause to find fault with men working day-work, but he had noticed the greatest waste of material he had ever come across had been indulged in by piece-workers. You might get the most physical exertion out of a man who worked piece-work, but you would not get the best work. If he (Mr. Phillips) was going to sea, and had the choice of going in a ship which was built by piece-work, or one that was built by day-work, he would much prefer the latter.

Mr. Hodgson Pratt said he hoped that, if any practical result were to follow this discussion, the form participation would take would not be that of giving a few small sums in the shape of bonus at the end of the year, which would be a very small step in the desired direction, but that the main object steadily kept in view would be the permanent identification of interest between the workmen and employers in the same house. That would not be realised by simply giving a bonus at the end of six or 12 months. The great object should be to make the workmen gradually more and more partners in every concern in which they were employed. What was wanted was to do away with the sharp line of division between the two classes, and to make every workman a capitalist as well as a mere wage-receiver. *It was quite clear, from the experiments of Leclaire*

and others, that not only increased industry and desire to prevent waste would be the result, but that, in every form, the identification of interest on the part of all employed must bring to the surface ideas and suggestions as regards processes, which could not fail to be beneficial. It had been pointed out over and over again that many of our industries were in a very precarious position at the present time; that, in many departments, we were beaten in competition. All this tended to show that England was now undergoing a considerable crisis, and the future depended on her undergoing an industrial revolution which should enlist a greater amount of interest in her manufactures. Compare the present state of things, in which the workman could have no interest in the firm, with that which would result if every workman in every large firm had an opportunity of being an holder of its capital. In that case intelligence would be constantly thinking how to increase the profits, and make the concern more successful. A vast number of minds all over the country would be electrified, so to speak, by that desire, and there would be forthcoming, which were absolutely necessary, to enable us to compete successfully with other nations. One word with regard to Messrs. Briggs' system, which had been alluded to. All the facts which went to show that there was a fault with that system, that there was a fault with the part of those employers. They did not treat the workman as an associate, but simply as a wage-receiver, what they chose to give him, and he was to state of things there could never be that confidence on both sides which was essential to the welfare of the undertaking. The Messrs. Briggs could have supposed for a moment that the workmen in their employ would consent to sever themselves off from their trade association in the most striking manner, how complete was the spirit in which they approached the question. There must be perfect equality of rights between the two parties. Messrs. Briggs showed themselves wholly unable to understand the problem, when they ventured to trench on the independence and self-respect of their workmen, dictating to them what they should do in their trade society. If employers wanted their movement to succeed, they must approach the problem with an altogether different spirit; treat their workmen with confidence and respect, and make them share in the capital.

Mr. Sedley Taylor said he would reply to the main objections which had been advanced to the principle of participation during the discussion. Mr. Wolstencroft had expressed an opinion that in the iron industries, piece-work would be found superior to participation. There were, however, theoretical objections of much force which made for the case against the former system. Participation was the excellence of work in every direction. Piece-work, though it increased the quantity of production in a given time, had no tendency to improve quality or enhance economy to any degree which would just pass muster with a practical examiner. But theoretical considerations all they had to judge by. They had the case of the important firm, Billon et Isaac, at Genesee, the managing director and a large majority of the men had stated, as their deliberate opinion, that piece-work was no effective substitute for participation in profits. The two systems were, however, being worked together without the slightest result, as was, in fact, done in the establishment of the firm, and in many other participating houses of the continent. The same speaker had denied the principle of participation to coal-mining, on the ground that the colliers were paid only for the coal actual to the surface in proper condition. He (Mr. T.

been informed, during a recent visit to the coal-field, that a great preventible waste of coal occurred in that industry, which payment by the miner would diminish in the slightest degree, but which still would directly tend to check. He had seen that large quantities of the timber used for the workings were constantly getting buried in the debris thrown out in the hewing process, and mostly lost. The pitmen had no interest in preventing this waste, and, rather than make their present position of the labour required to remove debris a position of safety, rarely hesitated to let it go for good and all, under the unseemly small bribe made in the operation of hewing. Payment of the miner actually tended to encourage this waste, and participation in profits would teach the miners to see it as directly injurious to themselves. He went to the very satisfactory statement which was made by Mr. Lloyd Jones that there was no apprehended hostility on the part of trades unions against a movement for industrial participation. The important letter had reached him (Mr. Taylor) Mr. Burt, M.P. for Morpeth, whose connection with the miners' union was well known. "I am glad," Mr. Burt, "that you are carrying on your efforts for co-partnership, or, as you well express it, share by the labourer in the profits. I quite agree with your views, and wish you every success." A statement which had the support of Mr. Burt in the aid of Mr. Lloyd Jones and Mr. Howell in the end no reason to anticipate an excommunication. Mr. Trowby had objected to Leclaire's system as it afforded no outlet for individual enterprise, if a man started in business on his own he would lose whatever he had deposited in the firm. As far as promotion to higher employment in the house itself was concerned, the Leclaire offered to unswerving talent and one most exceptional "outlet." The posts of and even those of the two managing partners, a partner, and obtainable solely by merit. M.M. and Marquet, the present heads of the house, began work as simple apprentices, and owed their honourable and lucrative positions exclusively to their own abilities and high principle. In employment by the house for a private enterpriser of the mutual aid society would lose his right to a retiring pension, but he would try with him the result of cash payments, 15 per cent. on each year of his work for the firm; it would be his own fault if he had not fully capitalised. Mr. Trowby's objection, admittedly, of much greater force against the system of long-deferred participation; it was, however, borne in mind that that system was the case, not of workmen, but of clerks, and only under very exceptional circumstances became employers of labour themselves, and addition was, as a rule, limited to the attainable confidential posts immediately below those held by the capitalists at the head of the concern. Thus situated, a permanent connexion with one firm was a distinct advantage, and the tie in M. de Courcy's system would, therefore, be heavily felt by them more than by workmen whose names involved frequent changes of employer. In spite of this view, that the entire surplus profits allotted to the workmen whose more effective labour had them into existence, he would reply that the chief advantage must be offered to the emulいた for the time and trouble which he would be required to expend in organising and superintending industrial relations. Much thought and labour would be required to making the change and in execution, and employers could not fairly be asked to make such efforts, unless on behalf of a mutual advantage. Mr. Shipton's pro-

posal to limit the interest on capital invested in production to 6 per cent., without making any allowance for the great differences of trade risk inherent in different industries, could not possibly be entertained. The same speaker's apprehensions that participation would lead to "nigger driving," and premature exhaustion of the labourer by an increase in the hours of daily work, lacked all support from the experience of participating houses, where the hours were no longer, nor the work more physically exhausting, than in concerns carried on in the ordinary way. It was by united and heartier work, not by intensified physical exertion, that the happy results of participation were to be achieved. In order to show, on the authority of a well-known political economist, that participation in profits approached the problem of capital and labour from the only point of view which offered any prospect of a solution, he would quote the following passage from Mr. Fawcett's work on "Pauperism":—"It is vain to expect any marked improvement in the general economic condition of the country, as long as the production of wealth involves a keen conflict of opposing pecuniary interests. The force which men can exert may be completely neutralised, if they are so arranged as to contend against, instead of assisting, each other. Similarly, the efficiency of capital and labour must be most seriously impaired, when, instead of representing two agents assisting each other to secure a common object, they spend a considerable portion of their strength in an interminable contest. All experience shows that there can be no hope of introducing more harmonious relations, unless employers and employed are both made to feel that they have an immediate and direct interest in the success of the work in which they are engaged." He was personally authorised to say that the Postmaster-General was prepared to repeat, with even accentuated emphasis, the strongly favourable opinion on industrial participation expressed in the volume just referred to. Mr. Taylor concluded by again urging the advisability of forming a society to promote the practical study of participation, and by renewing his request that conditional adhesion to such a society might be forwarded to him at Trinity College, Cambridge.

The Chairman said he must add one word of explanation of the remark which fell from him on the opening night with regard to trades unions. He merely threw out the suggestion that trades unions might be one of the possible obstacles to the spread of this scheme. He did not make any assertion on the subject, but he was aware that unions did not exist in France, where these participation schemes flourished. He was still bound to think to a certain extent that the trades union organisation, on the part of the men or of the masters, did present certain obstacles to that familiar intercourse between individual master and man which was so desirable, but he could hardly regret having thrown out the remark, because it had elicited such emphatic repudiation of antagonism to the principle of participation on the part of leading unionists. He could not believe that in England—where capitalists were known to bestow £100,000 on founding a library or giving a park to the people, as some men did in the North of England, thus devoting almost the whole of their accumulation in gifts to the place where their wealth was made—that men actuated by the spirit of Leclaire would not be forthcoming. He thought that when such an experiment were set before them, men of the stamp of Hugh Mason and Firth would feel infinitely more satisfaction in spreading their munificence over their whole lives, than in deferring it to the end, and then pouring it forth in this generous and wholesale fashion. In conclusion, he proposed a vote

of thanks to Mr. Sedley Taylor, and endorsed his desire for the foundation of a society to disseminate information on the subject of participation in profits. At these discussions there had been a more marked attendance of gentlemen representing the working class than the employers, and in order to carry on the subject, he hoped that at the next meeting they might secure the attendance of several large employers of labour.

Mr. George Shipton seconded the vote of thanks.

Mr. Crace, jun., said, as an employer, he begged to add his voice to the vote of thanks, as he felt very much indebted to Mr. Taylor for bringing the subject forward.

The vote of thanks was carried unanimously.

#### FOREIGN AND COLONIAL SECTION.

Tuesday, March 1st, 1881; Sir HENRY BARKLY, K.C.B., F.R.S., in the chair.

The paper read was on—

#### THE LANGUAGES OF AFRICA.

By Robert M. Cust,

Honorary Secretary to the Royal Asiatic Society.

It may be asked why the subject of language is brought forward in a Society whose primary object is the illustration or advancement of Arts, Manufactures, and Commerce. The reply is, that language has a very intimate connection with the development of these agencies, and the disclosures made in the course of the study of a language, throw a light upon the social and intellectual characteristics of the people who use it. Language is indeed a Science, but the method of conveying sounds to writing by symbols is an Art, and one of the most ancient, continuous, and interesting. The presence or absence of certain words in a language have a historical value. How shall we account for the Monbutto, on the River Welle, using the word "tobboo" for tobacco? After all, the commerce of thought is the greatest and oldest form of commerce that the world can have known, and no manufacture is older or more widespread, or more ingenious, or representing more clearly the line betwixt man and the lower order of creation than the manufacture of words, which has been going on without cessation ever since the world began.

I do not presume to claim a personal knowledge of any one of the hundred languages of Africa which pass under review, except Arabic, which is an imported alien. My statements rest not upon individual speculations, but upon the practical collection of facts by one class of scholars in the field, classified and arranged by one or two great comparative philologists in the cabinet, and thus presented to the notice of anyone who has the taste to study the subject. Every statement must rest "upon authority" and it is always better to give at once the name of the authority. I have followed not blindly, but with deference, one of the greatest living comparative linguists, Dr. Frederick Müller, of Vienna, who has given us his views in three famous works, "*Reise der Novára*," "*Ethnologie Allgemeine*," and "*Grundriss der Sprachwissenschaft*," only a portion of which last has as yet appeared. In these volumes, the whole of Africa is embraced, and a provisional classification suggested, but certain portions of the field are occupied by three other distinguished German scholars, the

late Dr. Bleek, in South Africa; Dr. Koell West Africa; and Professor Lepsius, in North East Africa, and a great diversity of opinion found to exist upon many points. Scores of learned English, French, German, and American scholars have handled different portions of the subject, and contributed good, sound bricks to the great edifice. Some attempts have been made to popularise this knowledge in England, by Stanford, in his "*Compendium of Geography, Travel*," and by Hovelacque, in his "*Linguistique*," but in both volumes all that is reliable has been derived from Dr. Frederick Müller, in the case acknowledged; in the other, this acknowledgment has been forgotten, and consequently the value of the communication is much diminished.

It is as well to state in advance, that our knowledge is still most imperfect. It cannot be with regard to any of the sub-divisions of the subject, that we have, at our disposal, the materials available for forming a definite opinion. A traveller has brought home the names of tribes, speaking separate languages. In some cases a scanty vocabulary represents all that is known of the words, and a doubtful representation in a map is all that we know of the habitat. Now, the two elementary requirements for linguistic knowledge of the lowest order are a language-map, showing distinctly the habitat of the people, and a vocabulary of the extent, showing distinctly the words which are in use, taken down on the spot, or from the lips of individuals to whom the language is their proper tongue in habitual and actual use. We have very much the same knowledge of the languages of Africa, that a geologist has of the face of the globe, i.e., a tolerably accurate acquaintance with the languages spoken on the coast round the Continent, with an occasional peep into the interior, and a visionary speculation on the subject of the centre.

The ancient nations of Europe and Asia have left records of their languages, as spoken in times, in literature or monumental inscriptions. With the exception of Egypt, Abyssinia, the Phœnicians of Carthage, and the Tamaseq of Libya, Africa has no record of the past. The seed-plot of all existing alphabets of the world is found in the hieroglyphics of Egypt, but no native of Africa has devised a practical form of writing: the syllabary of the Vei on the West Coast is merely an ingenious adaptation of an old system to new symbols, and not an original invention. In considering the languages of Africa we have no means of comparing the past with the present; our task is limited to recording what we find spoken by the people, and to reducing this record to such a form of classification as is possible. A century hence some form or other of the Roman alphabet will be the written character of nearly the whole of Africa, being adopted by the missionaries and European settlers, east, west, and south. The Arabic character will be retained for Arabic, and such of the vernaculars as are by half-bred Mahometans; the Abyssinian Libyan form of script, even if they survive in their own localities, will never be propagated beyond the coast.

I accept the classification of Frederick Müller as the best that is possible to devise in the present state of our knowledge; it admits of unlimited

nds the Bantu family; it is exhaustive Semitic and Hottentot; and approximates the Hamitic. The Nubab-division, still most imperfectly and the Negro sub-division is merely unclassified languages are roughly being analogous to the Turanian and the linguistic scholars of a quarter ago, without any pretence to mutual connection. Over and above the by travellers or word-collectors, is de (which no man can as yet number) tongues, which it must be left to ions to discover and record; and, till as place, no one can presume to say it of the languages is complete. And rather complication, that writers conclude the fact, that such and such a ying out, and, as this process has n for centuries, leaving not the s on the sands of time, an idea may w remote is the solution of the origin of human speech.

consider each separately.

tic family (for it is a family in the of the word) is well known. It Indo-European in being inflexive, of inflexion is quite peculiar; it is

most beautiful and symmetrical, but no explanation has ever been given of its origin. We find it in full development in its earliest records. The Book of Genesis gives an account of the creation of the world, but the words used for that account indicate a language in a very high state of development, and this characteristic is sharply brought out by contrasting the refined mechanism of the speech used by Moses with contemporary Egyptian records. The influence of the Semitic on the Hamitic group, or *vice versé*, as some assert, is of the slightest. The Semitic nation were at all times alien in Africa, but it received from Egypt the precious gift of alphabetic writing, which it handed on to the rest of the world, as if it were of its own proper invention. There are two branches of the Semitic family, that of the North Coast of Africa, and of Abyssinia.

The Semites possessed the eastern flank of the Nile valley from a remote period. The notorious subjugation of Egypt by the Hyksos, and the descent of the Hebrews into Egypt, have left no linguistic traces in Africa; but the colonisation of Carthage from Phœnicia has left its indelible trace in monumental inscriptions, in spite of the attempt of the Romans to destroy all trace of the foreign culture of their defeated rival. Centuries later, the Arabians conquered the whole northern coast of Africa, beyond even the pillars of Hercules, and Arabic supplanted the old Egyptian language in the Nile valley, and pushing aside, if not destroying, the Hamitic languages of Numidia and Mauretania, became the dominant languages of Tripoli, Tunis, Algeria, and Morocco, with a distinct dialectic variation from the pure form of the Arabian desert, and the Korán. A third Semitic invasion of Africa took place from South Arabia across the Red Sea, and is known as the Ethiopian or Geez, the language of Abyssinia. In course of time the ancient form of speech gave way to the modern Tigre, and the cognate Amháric. These are spoken by a Christian population in a retrograde state of culture. Travellers have brought to notice two other distinct Semitic languages, the Harári and Saho, on the flanks of Abyssinia, but of no importance.

The influence of the Arabic extends far beyond the limits of the settled populations of particular kingdoms. It is the vehicle of thought over the greater part of Africa, either in the mouths of the Bedouin Nomads, who surprise the travellers by their unexpected appearance, or of invading conquerors, such as the Sultan of Zanzibar; of enterprising merchants, such as the slave dealers, who are generally half-bred Arabs; of dominant races, such as that of Waday, in Central Africa; and lastly, it is the instrument of the spread of Mahometanism, and of whatever culture existed independent of European contact. Up to this time it has had entirely its own way, both as a religious and secular power, but it may be presumed, that its progress will now be checked by the powerful intrusion of the English, French, and Dutch languages, and the resuscitation and culture of the numerous, strong vernaculars, which are ready to the hand of the European civiliser and instructor. The Arabs have left names in their language, Kabail, Kafir, and Swahéli, which can never be forgotten.

II. The Hamitic languages come next in order;

they are presumed to be aliens from Asia, but at so remote a period, that the tradition fails. It may be bold in the present state of our knowledge to call this sub-division a family, it will be safer to style it a "group," with marked resemblances. It may be sub-divided into three sub-groups—(1) Egyptian; (2) Libyan; (3) Ethiopian. They probably have linguistic relations to each other, but they have not as yet been worked out, so as to win universal concurrence, in the sense that the inter-relation of the Semitic language is admitted, as a fact of science. All the languages of the first sub-group have passed away from the lips of men; the Coptic died some centuries ago, and has agalvanised existence as the vehicle of religious ritual; the Egyptian died before the Christian era, and as the tradition of its interpretation died also, it became linguistically extinct, or unintelligible, until revived by the genius of scholars of this century. As records carved on stone exist in this language, fully developed both as to its grammar and triple mode of writing, as far back as 4,000 years before the Christian era, no nation in the world, and no family of languages, can compete with Egypt and the Egyptian on the score of antiquity. Moreover, in the handling of words and grouping of sentences, we become aware that we are dealing with an instrument of thought indefinitely more ancient than the most ancient of Semitic or Arian records. Egyptian had its day, and under Greco-Christian influences passed into Coptic, which again disappeared before the inroad of Arabic, thus supplying one of the most notable instances of a nation changing its language, as few will doubt, that the Fellah of Egypt is the lineal descendant of the Egyptians as depicted in the monuments.

To the west of Egypt, along the coast of the Mediterranean, stretches that vast country known to the ancients as Libya. Herodotus, the father of history, knew about the Libyan tribes, as Greek and Phœnician colonies were settled on the coast. This region was known to the Romans as Mauretania, Numidia, and Getulia. The Aborigines outlived the Phœnicians, Greek, Romans, and Vandals, and still struggle against the Arabs, Turks, and French. The old Libyan language had no literature; it is dead, and is only faintly guessed at by inscriptions. The region is now known as Tripoli, Tunis, Algeria, Morocco, and the great Sahâra. In one sense, the name "Berber" may include all the Hamitic forms of speech of this sub-group, but other terms are met with, either dialects, or separate languages, Kabyle in Algeria, Shilwa in Morocco, Tamâseq in the Oasis of the Sahâra, Zanağa on the frontier of Senegal. The extinct language of the Canary Islands, the Guanche, belonged to this group. The French have contributed a great deal to the knowledge of this branch of the Hamitic group, in which there is an entire absence of culture, and the majority of the population is nomadic and savage.

The Ethiopian sub-group of the Hamitic group lies along the Red Sea, intermixed geographically with the Abyssinian branch of the Semitic family already described. The languages are:—The Somali, Galla, Beja or Bishâri, Fulâsha, Dankâli, and Agau. The Victoria Nyanza occupies a remarkable ethnical and linguistic position. It is here that the Bantu, Negro, Nuba-Fulah, and Hamitic groups impinge on each other. Mtesa,

King of Uganda, is credited with being of origin, ruling over Bantu subjects. Our ledge of the tribes to the north of Victoria is too imperfect to arrive at any certain sions. No Semitic influences have been felt in the culture, religion, or language of races. They are entirely uncivilised, culture, generally pagan, nomadic, and savage.

III. We pass to the third group, the Fulah, the least well-known, and the most full classification. Up to this time we have with inflexible languages; all that remain in Africa is agglutinative. Ethnologically speaking, the Semitic, Hamitic, and Nuba-Fulah belong to the "lank curly-haired" races. All that remain in Africa consists of "woolly-fleecy, or woolly-haired" races. It does not follow that linguistic fissures should be the same as the and we know that the contrary often is. Frederick Müller lays it down that this group, whose habitat is partly in the midst of the group, and partly on their northern frontiers, distinctly separate from the Negro, both by appearance, and other certain ethnical details. It occupies a position midway betwixt the Negro and Negro; and here let it be borne in mind that the Bantu family is supposed to occupy the same intermediate position; but the Bantu in their physical and physiological characteristics take after their Negro progenitors, while the Fulah approximate more to the Hamitic connection between the Nuba and Fulah by no means certain. Let us consider separately.

The Fulah family is found on the West coast. The word means "yellow." The Fulah call himself greatly superior to the Negro, and place himself among "white men." He is found intermixed with the Negro from the Senegal in the west, Darfur in the east, as Timbuktu and Haussa in the west to the south. He first made his appearance as a plundering intruder, and he is a Mahometan in the kingdoms of Sokoto and Gandu the Fulah power. The name appears as Pu Fulah, Fulbe, Fellata, Fuladu. The Fulah has intermixed with the Negro, which has produced other varieties. Fortunately, we have an excellent grammar by Reichardt, and a translation of some chapters of the Bible by Baikie. Seven varieties of languages, or (for it is impossible to say which) are recognised, but Futa jallo, on the River Senegal, is taken as the standard. Its linguistic features consist of the use of affixes, and the existence of rational and irrational. The languages are accepted as belonging to one family, and are all back to the same mother-speech.

The Nuba sub-group reach from the field of the Fulah family eastward, to the field of the Nubian sub-group of the Hamitic group. The Nubians now inhabit the valley of the Nile from the first to the second cataract. They call themselves Barabra, and are Mahometan. Schlegel's narrative shows that they are a distinct race, superior in power and culture to the Pagan races of their group, into whose ranks they make inroads as merchants and slave-traders. It is remarkable that the Nubians must have been in their present habitat in historical times.

us does not mention them, and could not look them, had they been there. The first appears in Eratosthenes, who in the latter half of the third century B.C., as a great people, not subject to the hands of Meroë; they must have in the immigrated from the West. We read of migrations of the same race in the time of Adrian, 300 A.D. The name of other languages, closely connected with Nubian, are these races are wholly without culture and are, and imperfectly known, and dwell in the valley. With far less certainty the place, on the river Takázi and Atbara, known by the reports of the Roman Catholic priest, and the Wakuavi and Masai, who are known to us by the Protestant missionaries, are included in the Nuba sub-

Still more hazardous, and dependent on the collection of future material, is the ascribed to this sub-group of the numerous whose existence has been revealed to us by Schweinfurth and Junker, on the watershed of the Nile and the Welle. Unfortunately a rejected Schweinfurth's linguistic collection they are the Monbuttu, the Nyam-nyam, and the Golo. It must be left to the generation to decide with certainty concerning the language of these tribes. Before leaving the Nuba-Fulah, it may be mentioned as classified ethnologically with the Dravidian families of India.

The Negro group is the next. As stated as a mere bag, into which all the languages of woolly, fleecy-haired races have been as far as we know, they are all agglutinative that is but a slight link of connection; no group by no means extends all over but it comprises the great bulk of the Negro. A race with less inherent vitality have been extinguished by the trials which led to undergo, circumscribed to the south of the Bantu, pressed upon to the north Nuba-Fulah, and deported in millions by the Germans. The Negro may be said to share with the Bushman the honour of being the aboriginal inhabitant of Africa. The tract from the mouth of the River Niger is the seat of the Negro, but the return from America, or from the vessels, of freed Negroes of very mixed blood, affected this purity, and some of the races, containing Hamitic, Semitic, and African elements, are the finest.

Nothing about the languages of this group is accepted as provisional. We know neither of the variety of the languages, their reach to each other, or their dialectical variations, nor do we have full information regarding those of which we have vocabularies or lexical notes. We can hardly define the limits of the field of languages, and they are utterly devoid of literature. One thing is clear, they cannot have been derived from one source, though all, that are known, are agglutinative in construction. There must have been many distinct sources, for not only does the grammatical construction forbid the hypothesis of any original source, but there is no such uniformity of vocabulary as would support the idea.

The distribution extends right across Africa in its

broadest extent, from the West Coast to the Nile Valley, where, as stated above, the four groups meet, somewhere in the 4th or 5th degree of north latitude. Three great Negro tracts may be roughly hewn out:—1. The Western Coast; 2. The basin of the Chad; 3. The Upper Nile. The vast empty spaces on the map, both above and below the great Negro belt, warn us of the presence of a great *terra incognita*, and unrevealed millions.

This thought ought to make linguistic inquirers and speculators into the origin of the human race and language silent and humble. We gather from the pages of Dr. Moffat, that new languages were coming into existence under his eyes; and from the pages of Dr. Koelle, that old languages were dying out. Schweinfurth, Livingstone, Stanley, Nachtigall, Rohlf, and every explorer, bring back specimens of new vocabularies, or vague indications of new languages, not understood by their African followers. Even the vast collections in Dr. Koelle's monumental work, "Polyglotta Africana," resemble a handful of shells picked up from the sea-shore at random, and useless, until they pass under the hands of the skilful assorter, and some of them not of much use even then.

In this group we have many noble grammars, the work of great scholars; we have numerous translations of the Holy Scriptures, and plenty of religious and educational books; we have grammatical notices of the greatest value, by Frederick Müller, of thirteen of these languages in his "Grundriss der Sprachwissenschaft," and in his "Allgemeine Ethnologie" we have the best classification of the group, that the materials available allow him to make. We find twenty-four sub-groups, to which I add another, for the dwarfs or pigmies. Of these, eleven sub-groups represent single and isolated languages, which admit of no relation to any other known variety. This by itself suggests, that the linguistic phenomena of the region have not yet been exposed to view. We do not find isolated languages, except in rare cases, elsewhere, and they generally are survivals of extinct families. The remaining fourteen sub-groups comprise a list of names, some of which are well known as the vernacular of great populations, such as the Susu, Vei, Temne, Yoruba, and Nupe, and others can, with difficulty, be traced in the pages of some traveller. Moreover, over and above these, there are other names to be gleaned from the journals of later travellers and missionaries. On the West Coast, the best known sub-groups are the Mandingo, Fulup, Temne-Bullom, Wolof, Bornu, Kru, Ewe, and Ibo. In these linguistic categories will come the French colonies on the Senegal, Sierra Leone, Sherborough Island, Liberia, the Grain Coast, Ivory Coast, Gold Coast, and Slave Coast, the kingdoms of Dahomé and Ashanti, and Bornu, Lagos, the Yoruba country, the basin of the Niger, as far as we know it right and left. In the Chad Basin, comes a sub-group of languages very faintly known. In the basin of the Nile and its great tributary, the Bahr al Ghazal, we find the languages of tribes of Bari, Dinka, Nuer, Shilluk, alluded to by a succession of travellers, and some of whom press upon the Hamitic, Nuba-Fulah, and Bantu groups, near the source of the Nile. Of the additional Pigmy group, we have some notices with regard to the Akka. As an interesting linguistic phenomena, it

is recorded, by more than one observer, that the peculiar linguistic feature known as "the click," generally connected with the Bushman, Hottentot, and the Káfir sub-branch of the Bantu family, exists in the speech of the races of the Upper Nile. This, coupled with the ethnical feature of the smallness of stature of some tribes, seem to indicate the existence of some aboriginal inhabitants antecedent to the present occupants.

We must recollect that the Negro type is a very marked one, and appears distinctly on the monuments of old Egypt 5,000 years ago, and though it may have undergone much admixture in the interior, it is pure on the coast. Of the purity of the languages, we cannot speak with certainty. The presence of the Nuba-Fulah from the north, the presence of the Mahometan religion in their midst, the influence of European nations and Americanised Negroes on the coast, must leave an influence. The Hausa is the great commercial language of Central Africa, far exceeding the limits of the region occupied by the Hausa race. It is an isolated language, and has borrowed from contact with Hamitic and Semitic races certain characteristics. It is spoken even as far north as Tripoli. It is attributed by one scholar to the Hamitic group, by another to the Nuba-Fulah, by a third to the Negro group. It might have been presumed, that there was a general consensus that these Negro languages were independent of any other group of languages; but so great a scholar as Bleek has laid it down, that some of the Negro languages actually belonged to the same family as the Bantu, and others were related to them. This shows how far we are at present from any certainty on any portion of the subject, from the absence of sufficient material.

V. The Bantu Family. The veteran, Dr. Krapf, claims the merit of the great discovery, that a single family of languages prevailed throughout Africa, south of the Equator, with certain reserved tracts for the Hottentot and Bushman. It was indeed a great discovery, announced by him in 1845, under the name of the Zinjian, a thoroughly unsuitable name, or Nilotic, a thoroughly inapplicable name. The name Bantu, or "men" is now accepted. In spite of the wide spread of this family from shore to shore, there is unmistakable evidence in their genius, their phonetics, and their vocabulary, that all the languages had a common mother: they can be dealt with in the same manner as we deal with the Arian, Dravidian, and Semitic families. Some of the features of the common parent appear in each of the descendants. The language of the Ama Xosa, commonly called Káfir, is allowed, for the present, to occupy the first rank. However, we must remember that the linguistic and ethnical strata are not always uniform. Some tribes in Lower Guinea speak a Bantu language, through belonging ethnologically to a pure negro type.

The language-field of this family exceeds that of any other, but it would be unsafe to state any, even approximate, idea of the population. New tribes are being made known to us every year. It is entirely independent of any other type of language, having remarkable features of its own. It has been well studied by excellent scholars, both in detail, in separate languages, and as a family, by great comparative linguists, such as

Bleek and Frederick Müller. It is distinctly aptative in method, but also alliteral, and as to remarkable euphonic laws. It has or frontier been influenced by alien neighbour we find in some languages clicks, borrowed the Bushman; and on the north-eastern from Hamitic influences are felt in conterminous guages. However, so little is known for certain that the development of this marvellous family be left to the next generation. Frederick Müller confidently indicates Semitic and Hamitic influences, which must date back to the infancy of the language.

Dr. Bleek, who had actual knowledge of subject, in addition to a profound knowledge of language generally, records his opinion of characteristics of the family. The words are syllabic, and the syllables open: diphthongs and derivative prefixes there were originally simple, but only two have a decided reference to the distinction observed in nature, being restrictions respecting reasonable beings, the singular, the other in the plural. The form of this latter is *ba*, actually or in other manner obtained from it. There are adjectives, and in their place, most general participial construction is used. The genitive is devoted by a prefixed genitive particle. The cases are indicated by prepositions; different kinds of verbs are formed by variation of the ending, moods, and the perfect time are indicated in the same way. The most simple form of the verb is the singular of the imperative.

Dr. Bleek paid also much attention to euphonic laws, which differentiated one language branch of language, of this family from the other. He showed that the languages differed from each other, more than the language of the Teutonic and Neo-Latin family differ from each other. The greater bulk of words in each language, though identical in origin, became wholly dissimilar, owing to the action of the euphonic laws which changed their form. The grammatical forms are also very different. And this difference is to such an extent that the Ama Xosa and Bechuana cannot understand each other, though in the same branch of the family. Dr Bleek took pains to illustrate a new form of what he calls the great "Grass law of transmutation of sound in Bantu. There are three clicks in the language of the Káfir sub-branch.

Some further explanation seems required of euphonic or alliteral concord, which is so striking a feature; the initial element of the noun, a letter or letters, or a syllable appears as the initial element of the adjective; the pronoun assumes the form corresponding to the initial of the noun for which it stands; the important part of the initial of the governing noun is detached to assist in forming the bond of connection with, and control over, the noun or pronoun governed in the genitive, *ex gratia*.

*i Zimmi Zami Zi ya li Zus Lissi Lami.*

Sheep (of) me they do it hear voice (of) me.

Bearing in mind that vast portions of the history of the Bantu language field have only imperfectly explored, or not explored at all, adopt provisionally the classifications into three main branches, the southern, the eastern,

rn. Each of these are again subdivided into ranches, which are sufficient for present sites, but which, as regards the eastern and ern must be indefinitely extended as time on, to admit of proper classification of the es of languages which come under observation. s classification is mainly dated on geographical a. In the southern branch there are three sub-anches (1) Kafirland; (2) Bechuána land; (3) kaa. In the first sub-branch we have the two est languages of the Ama Zulu, and Ama Xosa, amonly known as Kafir. It is the furthest moved from alien contact, and therefore the eant; the people understand the handling of heir speech, and make long and orderly orations. t may be presumed, that this was the earliest eans of Bantu immigrants; the marked resem- eance of the languages of the eastern branch with he languages of the western branch seem to ustrate that they both belonged to a later and mtemporary stream of immigration. Other nguages are recorded in this branch, Ama and, Ama Fingu, Ama Zwasi, and Matabéle, nd north of the Zambesi we come into contact ith tribes called Maviti, Watuta, or other names, ho are clearly of Zulu origin. It has been fully ustrated by scholars and grammarians, and there e large literature.

The Bechuána-land sub-branch comprises the guages of the majority of the vast population ich occupies the interior of Africa south of the pic of Capricorn, intermixed with Bushmen and b-blood tribes. They are separated from the ir sub-branch by the Drakenburg range; thward they extend to the Orange River, west- d to the Kalahári Desert, and northward as as the Lake Ngami. Being powerful, they e brought under subjection tribes belonging to e eastern and western branches of this family. re are two divisions of this sub-branch, the hem and western. The Eastern Bechuána tribes (the Basuto, who speak Sesuto; the Batan, e speak Setan; the Ba-tsetse, who speak e-tsetse; the Ba-mapela, who speak Se-mapela; e-puti, who speak Se-puti; the Ba-tlung, e speak Se-tlung; and others. The Western chuána tribes are the Ba-rolung, who speak olung; the Ba-hlapi, who speak Se-hlapi; the khwena, who speak Se-khwena; the Ba-kaa, e speak Se-kaa; the Ba-mangwato, who speak e-mangwato; the Makololo; and the Marutse- onda, on the Zambesi River, described by Dr. h. The words of this sub-branch sound harsh, its pronunciation offers a striking contrast to elodiousness of the Zulu, to which language, ver, it has a greater resemblance than to the r. There are no clicks in this sub-branch; there is an abundance of linguistic and educa- al works, for which we are indebted to the onaries.

e third sub-branch of the southern branch is ekeza, spoken to the north-east of the Kafir ranch, and some distance to the north of os Bay, and in the neighbourhood of so Marquez. A remarkable linguistic phen- on is vouched for by Dr. Bleek, that the occupying the entire coast-line of Zululand o speak Tekeza languages, which they e mentioned in favour of Kafir. Some few of eir tribes are said to speak among them-

selves Tekeza languages. Clicks are unknown, except in those dialects which have come under Zulu influence. The southern and Zuluisd tribes of this sub-branch are the Ma-neólosi, about 2,000 in number, in Natal; the northern are the Ma-tonga and Ma-hloenga, living near Delagoa Bay. The former seems to be a generic name for a variety of tribes inhabiting the interior of the Portuguese coast. Nothing has been published to illustrate the language of this sub-branch.

The eastern branch of the Bantu family is the creation of the last 20 years of exploration and missionary enterprise. The outlines of the great kingdom may be marked out with certainty; we must leave to future generations to fill in the details of the picture. No book that has passed under my observation has attempted it yet. I divide this eastern branch into three sub-branches: —I. The Basin of the Zambesi. II. Zanzibár. III. Victoria-Tanganyika. Under each sub-branch will be given the boundaries assigned to their territory. The whole will make up the region included in this branch.

The first sub-branch, the Zambesi basin, comprises an ever-increasing number of languages spoken by the tribes which come into contact with the missionaries, who have lately invaded that river and Lake Nyassa; the boundary of this sub-branch on the east extends north to an imaginary line separating it from the Zanzibár sub-branch, and on the west as far into Central Africa as exploration has extended. Considering the extremely scanty extent of materials, this grouping must be deemed entirely provisional, and only a convenient mode of collecting the names of languages known to exist in a certain territory. It is only by constant study of the narratives of travellers and missionaries that information can be gained, but the scientific character of the informants gives a value to what they state far beyond the random jottings down of the ordinary traveller. So far as it goes, it is accurate, but it goes only a very little way. We gratefully acknowledge a dictionary of some standing of the Nyássa, by Dr. Rebman, and a modern grammar of that language, by Mr. Riddell, of the Free Church Mission. This is the language of Lake Nyassa, and, if cultivated, and made the vehicle of instruction, will extinguish its weaker rivals. The Makúia is a language of great importance, occupying the table-land betwixt that lake and the Mozambique coast; it has been illustrated by an accomplished scholar, Mr. Maples, of the University Mission. Adjacent to or intermixed with the above, is a tribe called the Yao, or Hiau, or Ajáwa, whose language has been illustrated by Bishop Steere. Vocabularies exist of most of the others, and their habitat is generally known.

The second sub-branch is the Zanzibár; this extends from the island of Ibo, on the confines of the Mozambique territory, along the coast of the Indian Ocean, to the confines of the Galla and Wakuafi, where the Bantu family meet the tribes of the Hamitic and Nuba-Fulah groups already described. It embraces all the low coast, and the range of mountains running parallel to the coast, from the confines of the Zambesi sub-branch, to the country of the Masai of the Nuba-Fulah group. The dominant language throughout this sub-branch is the Swahéli, the speech of the coast,

as its name indicates, deeply affected by Arabic, used by Mahometans, and expressed in the Arabic character, and influenced by Arabic culture, but unintelligible to the savages of the interior. Those savage languages are being slowly developed by the labours of the missionaries. For the Swahéli all has been done, that is required, by Bishop Steere and Dr. Krapf, but of the other languages we have little more than brief vocabularies, or short notices, but it is a promise for the future to have got so much. It gives some idea of the rapidly expanding knowledge to mention that Frederick Müller only gives three languages of the sub-branch, which, owing to the diligence and energy of explorers, is now so rapidly expanding. It is pleasant to read in the reports that such a one is busy at the languages, has grammars and vocabularies, or a translation of a Gospel, in hand, all of which will find their way into my hands, and this is going on all down the line; and the funds are entirely provided by religious societies, who thus indirectly contribute to the extending of science.

The third sub-branch, that of the Victoria and Tanganyika Lakes, has been formed at a date entirely subsequent to the latest information available to Frederick Müller, and is the result of Stanley's famous journey across the Dark Continent, and the two great religious missions planted by the Church Missionary Society and London Missionary Society in answer to his challenge. If in five years so much has been done, what will be the result at the end of a quarter of a century? In connection with Victoria Nyanza many languages have been indicated, and their existence substantiated. In the language of the court of the King of Uganda, a portion of the Scripture has been translated; of the Nyamwezi we have a grammatical notice by Bishop Steere. The northern boundary of this sub-branch is the line of contact of the Negro, Hamitic, and Nuba-Falah groups already alluded to. On the east it is conterminous with the Zanzibár sub-branch, and to the south with that of the Zambési. To the far west an imaginary line must be drawn due south from Nyangwe on the Lualaba (which Stanley proved to be the Kongo), until it reaches the Zambési. Beyond that point the languages recorded must be entered in the western branch of the Bantu family, until, in due time, we have collected enough material to establish a separate group or family, as the case may be, for Central Africa south of the Equator, and north of the Zambési, which, with the exception of the track of Cameron, is now wholly unknown. In connection with Lake Tanganyika we have information from the south, owing to the exploration of the Geographical Society, and the visit of the Free Church Missionaries from Lake Nyassa. We have English missionaries established on one part of Lake Tanganyika, and French Roman Catholic missionaries at another. Nothing of a tangible linguistic character has reached us yet, but we are enabled to record the names and position of the tribes speaking distinct languages, or, possibly, dialects of languages, and leave it to time to fill in the picture. Nothing that is published can escape my observation, as every report, French English, or German passes under my notice.

The western branch of the Bantu family comprises the western half of Africa from the Namáqua-

land of the Hottentot family to the Equator, beyond it to the island of Fernando Po, and Cameroon Mountains on the main-land. northern boundary is that of the Negro gr and to the east, the imaginary line drawn Nyangwe to the Zambesi, thus leaving the 1 spaces of Central Africa to the explorer for west. This branch has three sub-branches Angola; (2), Kongo; (3), Ogoway-Gabún.

The Angola sub-branch comprises the Her Damaraland, and the Shindonga of Ov within British protection, and illustrated by matical and religious works. Crossing the Cunéne, we enter the Portuguese settleme Western Africa, and find a row of langua which our information is imperfect. Bunda best known, and is illustrated by gram works; but as to the language spoken in t terior, towards the kingdom of Muáte Jan know nothing. Serpa Pinto has brought to the Gwanqella language, spoken in the ba the Coanza.

Passing northwards, we come to the sub-h of the Kongo, reaching into the interior as Niangwe. Stanley, in his "Dark Continent," given us some glimpses of languages spok the Equator; and as we approach the Atlan have fuller information from missionaries travellers. Stanley himself is in the field; there are English and French missionaries pu their way forward, and every year will add t information. All those dreadful cannibals obstructed the progress of Stanley down the K will come into this category.

From the undefined confines of the sub-b of the Kongo basin, to the frontier of Negr north of the Equator, stretches the sub-bran the Ogoway-Gabún, including the islands c coast, and the Cameroons. Here we have s well-defined languages, illustrated by severa of considerable merit; the Fernandian, the Mpo the Dikéle, the Dualla, the Isubu, and the B For every scrap of linguistic knowledge in tracts we are indebted to the missionaries. limits of the sub-branch may be indefinitely p into the interior; and on the confines of Negr we may expect to find linguistic phenomena, s sideration of which may throw light into the c of both the Negro and Bantu stock.

VI. Driven down to the extreme south o continent of Africa, and only saved from e tion by the advent of the English, and b efforts of Christian missionaries, we find the and last linguistic group, and which, but fo smallness of the population, ought to form groups, as the component parts have no rel whatever to each other. I allude to the gro the Hottentot and Bushman. Their existenc however, important, as throwing some light o character of the earlier, if not aboriginal, in tants of the continent, as, unquestionably, we to deal with tribes broken and reduced by powerful inroad from the north of the great f family.

Sub-group "Hottentot." However, the may be spelt, or from whatever cause assigne not the real name of the tribe, who call them "Koikoib" (Men of men), and are called "L by their Kafir neighbours. They number 4 and are considered to have four dialects—

est and standard, spoken in Namaqua-land the north; Kora, on the Orange River; is spoken by the Eastern division of the and a fourth, and a very impure variety, neighbourhood of Capetown. To these added the Griqua, or Bastards, the Bushman and Hottentot, speaking a mixed dialect. There are many excellent works by Max Müller about and in this language, and it is considered to be sufficiently well-known. It is, all probability, its days are numbered. Max Müller records his opinion, that it is an African language, with no connection with any African or non-African form of speech, but morphologically agglutinative, the roots monosyllabic; there are genders and numbers, and inflexions; the pronoun is the vivifying element, and joined to nouns and verbs, differentiates meaning. The oral literature consists of songs and tales, which have been collected by visiting scholars. The great feature of the language is the existence of four clicks, each by a different position of the tongue; the nasal click is almost identical with the click of indignation, not unfrequently uttered by the Bushmen; the lateral click is the sound with which the nostrils are stimulated to action; the guttural click is not unlike the popping of a champagne cork, and the palatal click is compared to the crack of a whip.

A variety of opinions may be quoted as to the racial origin of the Hottentot. Hovelacque maintains that he is but a cross-breed, and that, therefore, he may be said to the isolation of his race; he has no pretence to independence of origin. Max Müller quotes Dr. Moffat as an authority for a resemblance of the Hottentot to the Bushman with that of some of the tribes of the Nile. Such assertions must, at the present stage of the inquiry, be supported by actual evidence, first hand, or withdrawn, as if supported by hearsay statements, they are of no value. We must deal with actual facts, and in the present instance, it is of no use hazarding theories of racial origin extending in a continual line down the continent of Europe. No doubt the Hottentot and Bushman are like the Basque in the survival of an ethnological and linguistic stratum, which has disappeared elsewhere, in the absence of written records, left behind. Bleek and Lepsius, whose names are frequently mentioned with profound respect, have distinguished the Hottentot with the Hamitic group.

Names of scholars whom we should aid to remember with this portion of the subject are, W. Theophilus Hahn, Henry Tindall, Wallmann, and Frederick Müller. To them we are indebted for many valuable notices, vocabularies, and a considerable amount of educational and religious literature. A missionary being invited by the Government to send books in the Kora dialect to the Hottentots, remarked, that his experience was that it was easier to teach the young to read Dutch, than to teach the old to learn at all.

The group "Bushman" comprises one isolated race, and is a very low state of linguistic development. The name was assigned to them by the Dutch, because they dwelt in the bush; they are called *San* or *Sanan*, and are totally disesteemed, and shunned by, the Hottentot and

Bantu. The language belongs to the monosyllabic order, as far as we can judge; there is no gender, the formation of the plural is exceedingly irregular, and, of the sixty ways of forming it, reduplication of the noun is the most common, as the most natural; but the use of the plural seems to be as abnormal as the formation. In some particulars there are analogies common to the Bushman and the Hottentot. Dr. Bleek made many years' study of this subject, having members of the tribe in his household, and collected materials for grammar, dictionary, and folk-lore, before his premature death. We can only hope that his successor, Theophilus Hahn, will complete the unfinished work.

It must be remembered that the Bushmen are a broken and despised race, in the lowest state of culture, neither pastoral, nor agricultural, but living by hunting, and nomadic; they have no appearance of tribal unity, and no chief. Before the English rule they were treated as little better than wild beasts. The "click" sounds are believed to be their original property, and to have been communicated by them, in always decreasing proportion, to the Hottentot and Kafirland sub-branch of the Bantu family; for the Bushman, in addition to the four clicks already described as a feature of the Hottentot language, has a fifth, sixth, and sometimes a seventh and eighth, and not only before vowels and gutturals, but before labials. Such sounds are almost incapable of expression by Europeans, and it would almost appear that they are connecting links between articulate and inarticulate sounds.

The Bushmen are of exceedingly small stature, thus opening out the question of their belonging to the now well-established tribes of pigmies in North and Central Africa. In appearance they seem to belong to the lowest order of humanity; they inhabit outskirts and desert places, and are shy and wild. We read, however, of tame Bushmen, the Babomuntsu, on the outskirts of the Basuto country, and other tribes with mutually unintelligible languages, with evident traces of Bantu influence in their form of speech, both wild and tame, within the recognised territory of Bantu sub-branches. Only lately it was mentioned by Miss Lloyd, the sister-in-law of Dr. Bleek, that a Bushman, who resided beyond Damaraland, had come under her notice, whose language was unintelligible to the Bushmen at Capetown. Frederick Müller states that they are found even as far as the Rivers Cunene and Zambesi, and even beyond. If such is indeed the case, we are not in a position to arrive at any final opinion about them.

One remarkable feature still remains to be noticed. No trace of the invention of writing has been found south of the Equator, but the Bushmen have acquired a wonderful power of painting scenes on rocks and in caves. Animals, human figures, dancing, hunting, fights, are portrayed with fidelity, and that the art has existed down to modern times is evident from the appearance of Boers in some of the fights. It appears that the art of sculpture was also known, and that the outlines of some of the figures are excellent.

Here ends my task. Twenty years ago there was a rebellion against the tyranny of the Arian and Semitic scholars, who attempted to cut down all languages to the length and breadth of their

method, forgetful of the infinite variety of the then dimly-discerned families and groups of agglutinating languages in Asia. The great problem of the origin of language, however, cannot be solved, and is not ready for solution, until the secrets of the languages of Africa, Australia, and America are revealed, and arranged in such order, that the lessons taught by the study of each of them may be considered with reference to the linguistic phenomena of the whole world, and this work will not be completed in this generation.

#### DISCUSSION.

Dr. Koelle said he could but express his delight at hearing that so much progress had been made in this country in the study of the African languages, since the time when he was occupied with the same subject, about thirty years ago. As an illustration, he might mention that, when he went to Sierra Leone in the year 1847, it was generally supposed that about thirty different languages were spoken in that colony, but his researches proved that there were upwards of 100. The Continent of Africa had been called dark, mysterious, and unknown, but it was now evident that it had, to a great extent, ceased to be unknown. Nevertheless, he was struck with the observation that, although we had made great progress in our knowledge of the Continent and its languages, there was still much to be done. For instance, it was mentioned that there were eleven unclassified languages, which showed that we might look forward to eleven new families of speech. As a matter of detail, he could not agree with the statement that the mode of writing adopted by the Vai people was not original, because it certainly had no connection with any other mode. It was a new invention, a syllabic mode of writing, and the Vai people had only a slight acquaintance with the European and Arabic methods, which were both alphabetical, consequently it was altogether new, and the marks themselves were also quite original. Mr. Hyde Clarke had traced some of them to the very old alphabets, but, as far as he could ascertain, there was no historic connection, only a physiological one. As far as the character of the writing was concerned, it was perfectly original. Again, the Negro languages were represented as being similar to the Turkish, as being agglutivative, but this would perhaps turn out not to be correct. For instance, the Damara language, which he had reduced to a grammar, was not agglutivative, and the same might turn out to be the case with a number of others. He was also struck with the remarkable character of the language in Darvar, of which he had an opportunity, some ten years ago, of collecting specimens from a black man in Jerusalem. It was a most singular language, but not agglutivative.

Mr. Cust asked if it were monosyllabic.

Dr. Koelle said no; it was exceedingly guttural, and the numerals were quite extraordinary, altogether different from those of any other African language with which he was acquainted. He hoped, from what had been already accomplished, that we might hope for still greater progress, for certainly a great deal yet remained to be done.

Mr. Hyde Clarke said he must join in the tribute which Dr. Koelle had paid to Mr. Cust for this paper, which all who had paid any attention to the subject would know must have involved an immense amount of labour. It did not appear to him that there was any need for apology for bringing it forward, and a full vindication was given, not only in the reasons he had mentioned, but in the very remarkable facts to which he had called attention. He had shown from the experience of the missionary societies that the simple propagation of religious tenets tended to the

promotion of external science, and the missionaries in East and West Africa were foundation for the promotion of the arts, which it was the object of the Society to study. It was mainly by the study of the languages like Africa, which possessed so many, to come into contact with the population and material interest, as well as the spiritual, which the labours of missionaries were devoted to study and written a good deal on this might be excused for differing in some points, because he could only say, as had said, that from year to year we had to alter on these matters. For instance, on one of Mr. Cust had called attention, the long short races of the Bushmen and the Akk he had the materials furnished him by the Geographical Society, he was led at one time to the opinion that these languages formed a feature, that there were assuredly relations between the various short races in the world. With this, however, of the real nature of language, he was not materially altered in his opinion. So it concerned, it was a matter well worthy that right across Africa there was a series of races, and that they were found in other parts of the world, speaking languages which indicated common origin. He regretted that he could not give the explanation of the distinguished scholar Muller, as to their having any connection in the distribution of language; but must accept dictum of Mr. Cust, that language could not be admitted in any way as a testimony of that great scholar came to make further research would find that the very languages which were attributed to populations having one character, by others partaking of different ethnologies. As to tufted hair, anthropologists considered it artificially produced. Latterly he had been attending more to the two groups which Mr. Cust named, the Nubian and the Negro, and, as far as his experience went, there was no black population in the world which, to all intents and purposes, was termed a white language, and there was no relation but spoke what, if you chose, you might call a black language. In the preface to the grammar of the Bornu language, by Mr. Cust, he gave most decided specimens of the real Bornu words and forms of grammar, and the languages of the world, and he might have still farther. He himself had gone the length of saying that the Hottentot language might be more than 200 words, with the Kolaria might compare the language of the Sant lately in rebellion against us, with that of whose assistance we hoped for in the three the West Coast. It would, he thought, be an advantage to the missionary cause, if from that district were sent to labour among the tribes in India. In the other distinguished scholar, the Rev. Dr. Schlegel, there was an observation bearing on this. He had studied this subject quite free from preconceptions, and must be pardoned for differing from great authorities, and he could not but mention, he found all the languages of the world excepting the Bushmen and Hottentots, in connection. Then came the difficulty which was put forward, how was it possible that there could be related which differed so in words; surely there could be no all languages having such different vocabularies. Dr. Koelle had pointed to the confounding of agglutivative and inflectional languages, and found that the grammatical forms distributed out the world were connected in a chain. The question to be determined was,

ect, according to the old system, to assume re was one primitive language of one set la, or whether, on the other hand, there was stem of language, in which several words were d to one idea, and possibly several ideas to d. Mr. Cust knew that even with regard to ptian and Coptic, there were several words with an one idea attached to them; and so it was the pre-historic languages, whether you went Caucasus, to Africa, or to America; for it had ought out by the researches of the American ent, that the same feature prevailed in the sign gs of the American Indians. If it were the at there were many signs used for one word, ight well be a very varied distribution of sounds. me another question, how was it possible to together, correlate, and compare these dis- t materials. There he thought Mr. Cust ell have applied to other very distinguished in Germany, who were studying psychological y, such as Dr. Karl Abel. They studied ounds, but the ideas represented, and thereby imed further criteria; they found two ideas d which were represented by one sound, and ound likewise representing those two ideas; e got, in the end, a means of checking other ions, and arriving at exact results from dis- materials. In conclusion, he would say, that et was of great practical value to the future ent of Africa, besides being a matter of the moment for the progress of philology and ogy. Mr. Cust had briefly pointed to one reason for this. Africa had never been con- those great conquerors who altered the anthro- und linguistic boundaries of Europe and Asia, tribes had been preserved. It was necessary, to guard against the confusion of race with

It by no means followed because we found pulation speaking a particular language, that be the language of that race. Therein, he lay a great part of the fallacy of Frederick in Liberia or Sierra Leone there were large nations speaking English, and we knew how obtained that language, but there were similar s in a state of utter savagery, speaking of equal culture, although of a different form, dd be correlated with the remains of other of antiquity. In fact, we had living languages ustration of Kluta, Babylonian, Etruscan, Iberian, and what was once most celebrated, not obscure, in the ancient world.

W. Wright (of the Bible Society) thought practical value of this paper was that Mr. shown as it were the tide-mark to which p had risen on this subject, and it would be ating in a few years to have a similar paper, how much progress had been made in the

It was interesting now to look at old maps and see what was known nine or ten years then take maps brought up to the present owledge, and mark the difference. He was sed with the scientific manner in which Mr. treated the subject; not dogmatically, for s were generally put forward by men who ey knew all about the subject, simply from ance of what the considerations of the ere. On the following day he should have to the committee of his Society a letter from ere, showing that his assistants were all the bees, and the New Testament was now

Bedman did the Gospel of Luke, but Bishop pleted the other parts. Mr. Hyde Clarke be glad to hear that the New Testament had ted in the House language, and that the ent was in progress. He must correct one in the paper, viz., that Bishop Steere uthor of the gospel in Yah; it was Mr.

Maples. He also thought it would be well for Mr. Cust to suspend his opinion as to what part of the world we owed language to, until more was known about the inscriptions now being published by the Biblical Archaeological Society. The whole Bible was now being printed in Basuto, and the work was going on in the Yoruba, and several other languages. He might promise the whole literary world that any translation made in Africa that came to the Bible Society attested they would print. He hoped that in the future, when kindly missionaries went into the country, and kindly explorers, instead of the greedy adventurers who had preceded them, and the more cruel imperialism that had touched the country at different points, they would stir up a kindly response in the hearts of the people, and that the travellers would be received into the country, and be able to explore, to their roots, the different languages.

Mr. Brandram said he had read about the African languages, as a student, but he had no special knowledge of any of them. Of late he had turned more attention to them on account of the light which they throw on the gender. This question of the classification of languages in accordance with the gender, had nothing to do with their relationships amongst themselves necessarily; but they apparently learned more about gender from these African languages, than from any other in the world. They saw it there completely developed, and apparently in embryo; and although those who studied the matter might hold the most opposite theories, it was to the languages of Africa they all appealed. He had classified the African language, for his own satisfaction, into three divisions; the Hamitic and Semitic, as having the most highly developed gender, in which the distinction of sex was the basis; then there were the Bantu languages, in which the distinction was based rather upon animate and inanimate considerations; and then there were the Negro languages in the centre, in which there was no distinction of gender at all, except the embryo, in the shape of prefixes and suffixes, which, according to Dr. Bleek, might ultimately develop into gender. He must add his testimony to the great value of the paper, in which all the information existing on the subject was brought together, and the authorities were referred to; a work of immense service to students, who otherwise might waste valuable time in doing what had been done already. He believed Mr. Cust was now doing for the African languages what he had already done for the Asiatic, and he begged to thank him for it.

Mr. A. W. Mitchinson, author of "The Expiring Continent," said that philologists were often in error in their explanations of the derivation of roots of languages. This arose from depending too much on theories and book-knowledge alone. A more accurate idea could be obtained only by personal acquaintance with natives. He had met Bushmen in Africa, whose words were the same as those of other tribes far distant on the same continent. The character of the country and population had altered since ancient times, and this had led the philologists to erroneously ascribe the origin of language to several places instead of one. The migration of people from one country to another influenced the character of the native languages. He found in his travels in Senegambia, on the Gambia River, and in Equatorial Africa, that many words as *ooka*, *otchag*, *idoo*, *tega*, &c., were both in meaning and sound exactly the same as Russian, Persian, Arabic, Hebrew, and other Oriental languages. The speaker mentioned that some of the natives in Africa had tails four or five inches long, derived, according to the tradition of the natives themselves, from gorillas or "devils," who had stolen native women. He concluded by denying that any of the natives of Africa were cannibals, except in cases of starvation, but stated that on the other hand they were great dog-eaters.

Dr. Mann remarked that the skill of the Bushmen in drawing, to which reference had been made, was a matter of considerable interest, and he himself had had some opportunity of noticing it. At one time, in the neighbourhood of Natal, there were a number of Bushmen who gave a deal of trouble, by coming down at night on the frontier of the colony, stealing horses and driving them away to the caves which they inhabited in the mountains. After some time, consent was obtained to send an expedition out to disperse them, and in a skirmish some were wounded, one of whom was taken prisoner. He appeared to be a lad, though it was not always easy to tell who were boys and who were old men. Having been cured of his wounds in the hospital at Pietermaritzburg, he was taken charge of by one of the magistrates, Mr. Proudfoot, with whom he lived for several years. This lad was very skilful in drawing, and it was often an amusement to call him out, and get him to show how he did it. He began by simply placing a number of isolated dots on the slate, or whatever he had to draw upon, which then resembled a constellation of stars; then after pausing, and carefully looking at these dots, he would carefully connect them together, until an animal grew up out of the outline, and you could tell at once what it was, whether a horse, a buffalo, or an antelope. He stated that that was the invariable mode of drawing, and he, Dr. Mann, had some reason to believe that it was so. A short time since, Mr. Francis Galton having expressed great interest in the matter, and a desire to have the facts corroborated, he had written to Mr. Proudfoot to ask if he could send him some drawings, but unfortunately he found that the poor fellow died about two years since of consumption. From his acquaintance with this man, he very much doubted the generally accepted notion of the very low organisation of the Bushmen. Though small in stature, they were quick in perception; and though their craniology was peculiar, it did not appear to indicate low organisation. This question was a very difficult one. One of the finest collections of skulls in the world was that of the Royal College of Surgeons, and some little time since he obtained five characteristic skulls of Zulus, from the field of Isandhlane. All those five were of a very distinct type, and Professor Flowers said a Zulu skull might be detected anywhere after having seen them, yet one of those skulls was, with one exception, the largest in the whole collection, though it belonged to a man who would probably be spoken of as a low organisation savage. Why the Kafir and Negro races, with such fine criminal development, were so backward in social civilisation, he did not undertake to say, but it certainly was not due to lowness of organisation.

The Chairman, in proposing a vote of thanks to Mr. Cust, said he could not pretend to any knowledge of the philological questions treated, but other gentlemen present, who were able to judge, had spoken upon this topic. His only excuse for occupying the chair was that, while at the Cape, he took a great interest in the ethnology of the various native races, and that he was fortunate enough on his return to be able to give Mr. Cust some materials which were of use to him. He also had the pleasure of being intimately acquainted with the late Dr. Bleek, and he need hardly say that he did all in his power to forward his investigations, especially in connection with the Bushman language; and he agreed with Dr. Mann that that was a most remarkable tribe, and by no means one of the lowest in organisation. It must be interesting to the Society of Arts to know that it was owing to a former President, the late Prince Consort, that Dr. Bleek was able to go to South Africa at all to prosecute his researches, and he might add, that for several years he received aid from the Prince's private purse. While out there, unfortunately, his untimely death put a stop to his studies, except so far as they were continued by his sister-in-law, Miss Lloyd; but he was glad to hear that the Cape Government had now filled up his place

by the appointment of Mr. Theophilus H. highly recommended by Professors Ma Sayce, and from his linguistic requirements in the interior, they might be results. He was surprised to hear it remained to be done in almost every part of the continent, especially amongst the Be Central Africa, but Mr. Cust had rendered by classifying and putting into a condition that was known about these languages, would serve as a sort of sketch for missionaries going to Africa. He had reminded them of the debt they owed to missionary societies, without whose aid what he himself and other students had would have been possible.

The vote of thanks having been passed

Mr. Cust, in reply, said he hoped one of the papers would be that Dr. Koelle would his slumber of 25 years, and again turn to the subject of the African languages. If up his own book as a basis, and add to his later experience, he would be doing service.

### THIRTEENTH ORDINARY MEETING

Wednesday, March 2nd, 1881; F. BRAMWELL, F.R.S., Chairman of the chair.

The following candidates were proposed for election as members of the Society.—

Appleby, Herbert, Durnley, Littleborough  
Attwood, George, F.G.S., F.C.S., 7, Regent's-park, N.W.  
Hall, W. H., Weybridge-heath, Surrey.  
Rattray, Netlam, 70, Gloucester-terrace, 1  
Richardson, Captain John Frederick,  
Houghton-house, Stoneygate, Leicester

The following candidates were balloted for as duly elected members of the Society:

Branston, F. R. E., 23, St. Swithin's-lane, 66, Lillieshall-road, S.W.  
Dollman, Charles, 293, Clapham-road, S.  
Greenwood, A., LL.D., Flaxfield College  
MacCallum, Andrew, 47, Bedford-gardens, W.  
Wilding, Samuel P., 23, Rood-lane, E.C.

The paper read was—

### LIGHTHOUSE CHARACTERISTICS

By Sir William Thomson, D.C.

For a lighthouse to fulfil its existence, it must not only be seen and recognised when seen. Besides its light, a lighthouse generally contains also, for thick or foggy weather that the light is seen, a sound-making appliance, which is not only to be heard, but which is immediately recognised to be itself else. Mr. Price Edwards, in his communication to the Society of Arts, of 15th Decem "Signalling by means of Sound," gave an interesting and clear description of the methods hitherto in use for this end

lition to the efficiency of light-houses; have occasion to return to the subject. Distinctive sounds, in relation to the several lights, have been adopted to give characteristics to the light itself of a light-house. Colour, now generally admitted to be suitable, as a distinction for lighthouse lights, is not in the proper use of it, which is to indicate different directions of the light by colours to mark rocks or other dangers, or the limits of navigable channels, we find characteristic qualities of lighthouses to be one or other of the following three :—

Flashing lights.

Fixed lights.

Occulting or eclipsing lights.

The unknown name "Revolving lights" is limited to flashing lights; but it is ambiguous, because the same revolving is also applied in many cases to proclipses of "Occulting or Eclipsing lights." The official description of the revolving light in the "Admiralty List of Lights," is as follows :—

"A revolving light, gradually increasing to a full flash, then decreasing to eclipse. [At short intervals in clear weather a faint continuous light is visible.]"

This fact, includes the description of the light :—

"The light is shown by flashes at short intervals, or by a continuous light at regular intervals."

The distinction of the fixed and flashing qualities, which is comparatively rare, constitutes an important characteristic light, described in the Admiralty List of Lights :—

7.—Fixed light with addition of white or red flashes, preceded and followed by a short

flash. This has really very little of complexity in its mental classification into the three classes of Flashing, Fixed, and Occulting.

In the case of a flashing light, the light is visible for only a fraction of a second, or from that to a longer period—and then disappears; and, for a longer time than the duration of the flash, the light is invisible, until it again flashes out as the fixed light there is no distinguishing characteristic whatever, but merely a light which is continuously and uniformly visible. The light is visible during the greater part of the time, like a fixed light, shining continuously. Characteristic distinction is given by a flash, or by a very rapid group of two or three flashes, or of short and longer flashes, occurring at regular periods, "flashes of which they have been called, cutting out, from the light its mark, by which it is distinguished and recognised to be itself a flashing light, in the very short time (from half a second to seven seconds at the most) of the group of eclipses.

#### I.—FLASHING LIGHTS.

In every flashing light there is a flash in the period, and thus the flash is the sole distinction

between one flashing light and another. Thus, in the "Admiralty List of Lights for the British Islands," for 1875, we find about 100 flashing lights of different periods, from the four-seconds' period of Ardrossan Breakwater light to the two-minutes' period of the upper light of Lundy Island, of the South Stack, Holyhead, and of one of the lights on Slyne Head, off the west coast of Ireland; and the distinction of each one of these 100 lights was solely its period as a simple flashing light, except in cases in which the objectionable distinction by colour was put in requisition. When it was determined to choose periods the same, or nearly the same, for neighbouring lights, it was found necessary to add distinction by colour, objectionable as this is if not enforced by necessity. Thus, for example, the Gull Stream lightship, in the fairway between the Goodwin Sands and the Kentish coast, is a revolving light of twenty seconds period, while the East Goodwin lightship, about six miles from it, is a revolving light of fifteen seconds period. Without greater accuracy than is generally to be found in the time-keeping of flashing lights, even on shore, the distinction between fifteen and twenty seconds could scarcely be relied upon, as given by the mechanism; and even if given trustworthily by the mechanism, the distinction could only be discovered by the sailor with certainty by the aid of a chronometer. To give a sufficient distinction between these two lights, therefore, it was found necessary to use colour; the East Goodwin was made green, the Gull Stream white. Again, the St. Agnes light, Scilly, and the light on the Wolf Rock, two far outlying lights, about twenty miles asunder, are each of them of half a minute period from flash to flash, and the sole distinction between them is, that the flashes of the Wolf light are alternately white and red, while those of the St. Agnes' light are all white.

The insufficiency of the distinction of flashing lights, merely by length of period, had come to be felt so strongly, that a very important fresh distinction was introduced in 1875, in the lightship then first placed on the Royal Sovereign shoal; the Group Flashing Light of Mr. Hopkinson, in which, instead of just one flash in the period, there are, in the case of the Royal Sovereign light, three flashes in the period, or, as may be in other cases, two flashes, or four flashes, the interval between the successive flashes of the group being much shorter than the interval from group to group in the whole period. In two cases in the English Channel, the North Sand Head and the Casquets, the new triple flashing light was introduced, to replace, by a group of three flashes in rapid succession, three separate lights which had been the characteristic arrangement previously; three fixed lights in the case of the North Sand Head, and three simple flashing lights in the case of the Casquets.

Mr. Preece has imprudently pointed out that Mr. Hopkinson's triple flashing light is the letter S of the Morse-Colomb flashing alphabet. Sailors, we may hope, are happily ignorant of this truth. The proverbial captain of the collier does not read the *Journal of the Society of Arts*, or he would be calling out to his chief officer—"Bill, was that a S, or a I, or a H, or a E?" Bill, if he was well up in dramatic litera-

ture, would reply, "Captain, there are things as no fellow can understand." I must say, however, that I agree with Mr. Preece, and think that, while many may find memory aided, none can be embarrassed, by an official statement of the Morse letter corresponding to any group of flashes or eclipses that may be chosen as the characteristic for any particular light. This, however, is a matter of comparatively small moment at present. The great thing is to find how lights may be most surely and inexpensively rendered distinctive, so that no sailor, educated or uneducated, highly intelligent or only intelligent enough to sail a collier through gales, and snowstorms, and fogs, all winter, between Newcastle and Plymouth, may know each light as soon as he sees it, without doubt or hesitation.

This object is fully attained by the triple flashing light, if quick enough. The triple flashing light of the Casquets, and of Bull Point (Bristol Channel), which are the quickest of the kind hitherto made, complete their three flashes in twelve seconds, after which there is an interval of eighteen seconds of darkness. These are, no doubt, very admirable and thoroughly distinctive lights; but it would be very much better if they were made three times as fast, which, with the existing machinery, could, I believe, be easily done. If this were done, they would show their flashes each in two thirds of a second, and with only a second of time between. Thus, the three flashes completed in four seconds, would be instantly recognised as a group of three, without the necessity of any counting either of flashes or of numbers of seconds of time in the intervals between the flashes; and, instead of having to wait in darkness for eighteen seconds the sailor would only have to wait six seconds, for a repetition of the triple flash.

The *Royal Sovereign*, the *Seven Stones*, the *Newarp* (near Yarmouth, on the east coast), and the *Saltees* (off the south coast of Ireland), all lightships, supplied within the last few years with the Triple Flashing Light, are, each of them, of one minute period, of which there is thirty-six seconds of darkness, and twenty-four seconds of flashing. These lights are all too slow to do full advantage to the Triple-flash system. When one of them is first seen, it is very apt to be confounded with an ordinary "revolving light;" that is, a single-flash flashing light. Even somewhat careful watching—at all events if the weather, or the distance from the light, be such as to leave any room for doubt—does not always immediately resolve the doubt. A sixfold quickening of each of these lights would greatly enhance its distinctive quality, and would make it really fulfil the condition pointed out by the Elder Brethren of the Trinity-house, as the object to be aimed at in every modern lighthouse, "That he that runs may read."

The satisfactory distinctions of Group-Flashing lights are exhausted in the groups of two or three or four flashes; because, to count five or six, or more, would be embarrassing, and liable to mistake at sea. It has been proposed to obtain further distinction, by using groups of longer and shorter flashes, as in Captain Colomb's Flashing Telegraph, now in general use, and very thoroughly appreciated both in the Navy and in

the Army; but there are optical difficulties of making, with satisfactory economy of long and short flashes, separated intervals of darkness in the group, and of long intervals of darkness between groups; and considering how very useful and satisfactory at sea is a light showing long light with short intervals, than even the quickest of flashing does not seem desirable to push the distance of flashing lights further than the double, quadruple groups. The periods for which which seem best adapted for practical all things considered, but most particularly value to the sailor, are as follows:—

Number of flashes in period.	Duration of each flash.	Duration of group.
One.....	$\frac{1}{2}$ sec.	$\frac{1}{2}$ sec.
One.....	$\frac{2}{3}$ "	$\frac{2}{3}$ "
One.....	1 "	1 "
Two.....	$\frac{1}{2}$ "	2 "
Two.....	1 "	4 "
Three.....	$\frac{2}{3}$ "	3 $\frac{1}{2}$ "
Four.....	$\frac{1}{4}$ "	2 $\frac{1}{2}$ "

It may be objected to the suggestion preceding table, that the quarter-second too short to be perceived with the same as flashes of five or six seconds duration. I alone can answer decisively the question with equal maximum brilliancy in each of quarter-second duration recurring seconds, or one of half-second recurring seconds, or one of one second recurring seconds, is the most easily to be seen at distance, or in hazy weather. From experiments already made, it has been concluded that one-tenth of a second is a long enough time to excite the sensibility and perceptive power, and it seems probable that rapidity of repetition of the contrasts between light and darkness is a positive advantage to the quicker flash to perceptibility, even when the observer has to look for the light; as does not know exactly in what direction which is the practical case of a sailor at sea to pick up a light, shortness of the time of visibility is of supreme importance. All considered, it seems most probable that the double flash recurring every two seconds is very much more easily and surely picked up at sea than a flash of one second recurring every eight seconds.

Before passing from this subject of flashing lights, I may be allowed to say that I find my impression of the vital importance of a light from a very practical man, the late Captain Morris, who, in 1866, showed us within a quarter of an hour of mid-ocean, where to find the cable had been laid and lost in 1865; Captain Morris, I well remember when, on one occasion in 1858 or 1865, I do not know which, in the Irish coast in dirty weather he said:—

"Those lighthouses should flash out their like your electric signals; every lighthouse should flash, and flash, many times in a minute, you which lighthouse it is every time."

the revolving light has often seemed to me, when I have been anxious to make out were in a gale of wind and rain."

## II.—FIXED LIGHTS.

623 lights numbered in the "Admiralty lights for the British Islands for 1881," 490 are flashing, and 21 are occulting (flashing," or "intermittent"); and similar ones are to be found in the official list of other parts of the world. Thus it is that fixed lights constitute the great part. The fixed light has a great advantage as to practical usefulness over the flashing light, being always visible. The superior brilliancy produced by optical condensation of the light is, in some respects, dearly bought, when the great diminution of brightness to the sailor, in its comparatively short periods of darkness, is taken into account. Those who praise the revolving light unduly for its superior penetrative power, seem to be overlooking its counterpart in optics to the great principle of dynamics—that what is gained in power is lost in time of visibility. The painful scanning of the horizon for a one-flashing light, is known to every one who has had occasion to look for one in practical navigation; and the comparative ease of picking up a light, and keeping sight of it when it is in difficult circumstances, is thoroughly appreciated at sea by sailors. Still, if the revolving light be seen at all, whatever be the difficulty of getting it up, and whatever the annoyance of sight of it and having to pick it up, it has fulfilled the object of a light. All are agreed in the maxim that the requisite of all sea lights is penetrative power; and if the fixed light cannot be seen at a distance, or in weather in which the light is seen, the fixed light has failed, and the revolving light has done its work for the

It depends very much on the special circumstances whether the same quantity of light, given uniformly as a fixed light, or condensed given out in flashes, with comparatively short intervals of darkness, as in the revolving light, is better in respect to being seen. In stormy weather, with heavy showers of rain or snow, a fixed light is much safer than a revolving light of much greater absolute brilliancy, as several successive flashes of the revolving light may be lost through passing showers, and the fixed light loses no chance of being seen between the showers. On the other hand, in a hazy or foggy weather of tolerably steady weather, a revolving light can be seen efficiently at a greater distance than the same absolute quantity of light, given out uniformly as a fixed

question of economy, the great first cost of the apparatus, special to the revolving light, is set against the greater consumption of gas, or fuel, to obtain in a fixed light, whether an oil or gas lamp, or an electric light, the same brilliancy. In many cases, indeed, the expense of the money spent on prisms, and lenses, and the loss of brilliancy in the revolving light, and in some cases the loss of brilliancy and perfect of the appliances

for the azimuthal condensation of fixed lights, would supply the oil required to give the same, or nearly the same, brilliancy all round the horizon. These circumstances are, of course, all to be taken into account by the proper authorities in respect to every project for a new lighthouse. But we have actually at present the great fact of 490 fixed lights on the coasts of the British Islands; and when it is considered desirable or necessary to give more brilliancy to any of them, this certainly is not to be done by converting it into a flashing light, but by making it a more powerful oil or gas light, or converting it into an electric light. Indeed, after Mr. Douglas's communication of two years ago (March 25th, 1879) to the Institution of Civil Engineers, on "The Electric Light Applied to Lighthouse Illumination," and the discussion which followed upon it, and considering the great progress which has been made since that time in lighting by electricity, we can scarcely doubt that, in the course of a few years, nothing but the electric light will be thought of for any new lighthouse of great importance.

The great defect of fixed lights at present is the want of characteristic quality by which the sailor, when he sees a light which really is a lighthouse light, may immediately feel sure that it is so, and not a steamer's mast-head light, nor a trawler's or fishing-boat's light, nor a light on shore other than a lighthouse light; and that knowing it to be a lighthouse, he may know exactly which of two or more possible lighthouses it is. The need for thorough-going remedial measures to remove this defect has been more and more felt of late years, and is now very generally admitted. Unless a second light is to be added, or the generally objectionable expedient of colour for distinction is in any particular case to be admitted, the only systematic means of giving characteristic quality to a fixed light is by means of occultations or eclipses; and hence the origin of the "Occulting" or "Eclipsing light." We may accordingly look forward to all, or nearly all, the important fixed lights of our coast being, without any very long delay, converted into lights of this class. It is satisfactory to find that during the last year the elder brethren of the Trinity-house converted one most important light, that of the North Foreland, and another very important one, the light on the west end of Plymouth Breakwater, into eclipsing lights, and that a similar improvement has been promised for five more of the fixed lights under their charge (Mucking, Lowestoft, Chatham, Flatholm, and Evan) within the official year 1880-1.

## III.—OCCULTING OR ECLIPSING LIGHTS.

The 21 eclipsing lights at present existing in the British Islands are described in the Admiralty list of lights. (See next page.)

To these is to be added the Cardross light on the Clyde, at present a red light, but which, before the end of next month, is to be converted into a white eclipsing light of the same character as the Craigmore light in Rothesay Bay, long-short-long-short. It was judged by the trustees of the Clyde Navigation, under whose charge this light is, that the long-short-long-short would be thoroughly free from liability to be mistaken for the occulting light (short-short) off Garvel Point,

## OCCULTING LIGHTS OF THE BRITISH ISLANDS, 1881.

No.	NAME.	PLACE.	PERIOD.	REMARKS.
12	Plymouth	On W. end of breakwater	Half-minute.	The light suddenly disappears every half-minute.
107	North Foreland	On head	"	The light suddenly disappears every half-minute.
282	Tarbet Ness	430 yards from the extremity of the point	3 minutes.	Visible 2½ minutes, eclipsed ½
306	Bu Stoer	South ear of Bu Stoer	1½ "	" 1 " " ½
315	Hebrides, Barra Head	Highest part of Bernera Island, South point of the Hebrides.	3 "	" 2½ " " ½
389A	Craigmore, Firth of Clyde	End of pier, Bogany point, Bute Island	11 seconds.	Five seconds of light, follow eclipses, long-short-long-ah
347	Greenock	Garvel point	8 "	Light for four seconds, with eclipses in the next four s
361	Troon Harbour	Inner end of pier	1 minute.	Visible 40 seconds, eclipsed
373	Galloway Mull	S.E. extreme	½ "	" 30 " "
418	Ribble River	S.E. of Stanner point, N. side of entrance	4 "	" 3½ minutes, "
442	Lynus	On the point	10 seconds.	" 8 seconds, "
464	St. Tudwall	West Island	10 "	" 8 " "
494	Bristol Channel	E. side of entrance of Parret River	4 minutes.	White with Red Sectors, visible eclipsed ½ minute.
512	Cork Harbour	Roche point, E. side of entrance	20 seconds.	" 15 seconds, "
521	Mine Head	S. side of head	1 minute.	" 50 " " "
536	Wicklow	On the head	13 seconds.	" 10 " " "
542A	North Bull, Dublin Bay	End of North Bull wall	14 "	" 10 " " "
555	Dundrum Bay	St. John's point	1 minute.	" 45 " " "
562	Belfast Bay	On elbow of Hollywood bank in 8 feet water	12 seconds.	Eight seconds of light, follow short and one longer eclips
566	Rathlin	Altacarry head, N.E. point of island	1 minute.	White with Red Sector, visible eclipsed 10 seconds.
600	Loop Head	500 yards, E. by S., from extremity of head	24 seconds.	" 20 " " "

three miles from it, and would, in the circumstances, give it a more telling characteristic quality than a single eclipse in the period or than any group of three eclipses.

It will be seen, from the preceding table of occulting lights that, with the exception of Hollywood Bank light, Belfast Lough, and Garvel Point, and Cardross lights, all on the Clyde, the distinction in each case is only a single eclipse in the period, and that except in nine of them, the period is one minute or upwards, but in all, except five, the duration of the eclipse is less than half a minute. In all the more recent eclipsing lights the period is half a minute or less, and the duration of the eclipse is at most five seconds. The tendency undoubtedly is to quicken the action still farther, following the example of the old Point Lynus light, with its eight seconds of visibility and two seconds of eclipse.

The necessity for a very short period is not so urgent in the case of eclipsing lights as it is in the case of flashing lights. A long period in the case of a flashing light means a long period of darkness, throughout which the light is lost sight of. The inconvenience of a long period in an eclipsing light is merely the length of time during which the sailor may have to wait to know which light it is; he never loses sight of the light except for the two or three seconds' duration of one of the eclipses. But quickness of each group is just as important to allow ready and sure identification of its character as is the quickness of a group of flashes in the group-flashing lights, of which I have already spoken.

The important question is now to be met—How may eclipses be best arranged to give the requisite number of characteristic distinctions, for the large number of fixed lights on our coasts which need distinction, with as little as may be of interference with the valuable quality of fixity? The answer, I believe, is by groups of eclipses

described as follows:—First—one, two or four very short eclipses, say of less than one second each, separated by intervals of light in the group, and the eclipses following one another after in not less than eight seconds of undisturbed light; next groups of two or of three long eclipses, the short eclipse one second long eclipse three seconds, the interval between the eclipses of a group or and the interval of undisturbed light the groups of eclipses not less than eight seconds. I fixed upon the time one second after many trials of mechanisms to produce eclipses, I found that I could produce groups of eclipses at the rate corresponding one second for the short eclipse by a simple inexpensive machine applicable to a house, large or small, and of any variety of arrangement, whether merely with cones to the horizon, or with the additional cones required to condense into a particular azimuth.

A machine fulfilling these conditions is now at work in the college tower of the University of Glasgow, performing the short-long eclipses the following table for four hours every day. It has been doing this for a month, and shows no signs of wear. Indeed, there is no wear on the machine which is liable to wear in the years' regular service in a lighthouse. In the machine at present, because it has been designed for the plan of mechanism used in the Bank light, and Garvel Point, Craigmore, and Cardross lights, that is, a mechanism producing eclipses by revolving screens, and therefore applicable only to lights without azimuthal cones, is the only mechanism which can practically produce the groups of eclipses at the speed required to carry out this method of giving characters to fixed lights.

My proposal for giving character to fixed

not definitely limited to the ten varieties the following table. The short eclipse second, the long, three seconds, in every part the last; in the last case, the short a half-second, and the long eclipse, three seconds:—

description of the eclipse.	Time from beginning to end of each group of eclipses.	Period of time from beginning of one group to beginning of the next.
sig.	3 seconds	12 seconds

ag-short-long-short.	11 "	20 "

vious this plan may be understood immediately by any person learned or unlearned a description, or being told it by word, and that no knowledge of the Morse corresponding to the several groups of is needed. Indeed, if Mr. Preece and I not let out the secret, I might have forward this proposal without any argument of indebtedness to Morse or to Colamb, had I been disposed to omit to where credit is due for very brilliant ble inventions, and had I thought only y best way of putting forward my little in the manner most likely to promote doption by the lighthouse authorities. mly to add, in conclusion, that the highly suggestion of Sir Richard Collinson, to h and a low note in direct contrast, to asteric sounds for lighthouses, may be at systematically in a very convenient r using the combinations of the preced- with a high note instead of the short od a low note instead of the long be low note of the same duration as the ; the interval between the notes of each ut the same as the time of each blast; and al of silence between the group of blasts gor than the whole time of each group. fog-siren is used, there is no difficulty in e blasts as short as we please, and they might not to be longer than a half-second uarters of a second. Quickness is here, as ther nautical matters, of vital importance. e try for himself, sounding a high and a in rapid succession, or two high notes , or any other of the combinations of the table, and he cannot fail to be con- re is in each case a characteristic sound, ds no rational ear for its appreciation, and not be misunderstood by anyone who has r has read it as the description of the sound

understands is very easily read, and may be used with a crew in which there is no practical difficulty in such corresponding to the three half-second and three for the short and long eclipses.

of such and such a lighthouse, or has been told of it by word of mouth. The distinction between long and short blasts, as Mr. Price Edwards pointed out in his communication to the Society of Arts, already referred to, has not proved satisfactory in experience, and I believe this will generally be admitted to be the case by those who have experience of the working of the Morse system of long and short blasts of the steam-whistle or siren at sea. There is an uncertainty as to the instant when the sound ceases, prolonged as it often is by echoes, and in the case of the steam-whistle, an uncertainty also as to when it begins, which is very distressing to anyone trying to understand Morse-signals by long and short sounds. But corresponding signals by very short high and low notes following one another very quickly, with ample times of silence between the groups of sounds, are exceedingly clear, and may easily be distinguished, even when the sounds are barely audible.

#### DISCUSSION.

Dr. Tyndall, F.R.S., said there could be no doubt of the importance of the subject of the paper, to which he had listened with much pleasure, or of its growing importance, because the greater the number of lights there were, the greater was the liability to confusion between them. It was, therefore, a matter of growing necessity to be able to distinguish between lighthouses from other lights afloat and ashore. It might be imagined by any one who had been near to a lighthouse, especially if lighted with the electric light, that it could not possibly be mistaken for a floating light at a masthead; but he could assure them it was not only a possible, but an actual mistake; a candle in a lantern, placed in a certain position, was not to be distinguished by the sharpest eye from a distant electric light. Hence the necessity for the distinctiveness on which Sir William Thomson insisted. He (Dr. Tyndall) should himself lean to his view as to the utility of quickening the flashes, so as to bring them within the range of consciousness, and to present them without the labour of counting, or, at any rate, of looking at a watch. The Elder Brethren were by no means oblivious of the necessity for distinctiveness, and the beautiful apparatus devised by Dr. Hopkinson, for a triple or other flashing light—for he was not limited to the triple flash—and constructed in the workshops of Messrs. Chance, was obtained with the view of securing this object; and in a paper read by Mr. Douglass before the Institute of Civil Engineers, an elaborate scheme of signals was brought forward. He had been much interested in the experiments, which showed how easily gas lent itself to such purposes; and he might remark, that on the South Coast of Ireland there was a first-class lighthouse illuminated by gas. There a light of 300 jets of gas could be almost quenched and raised again in an instant by the simplest arrangement. With regard to the siren and sound signals generally, he might say that, at the present moment, the Elder Brethren were engaged in investigations. Sir Richard Collinson's proposal to use high and low-pitched notes in combination was of great value, and this would render the siren stations as distinct as he hoped the lighthouses soon would be. There was, therefore, a very healthy movement on the part of the Elder Brethren, which would be greatly promoted by the zealous efforts of Sir William Thomson, who brought his own individual experience to bear on it, who was fettered by no particular antecedents, but who had simply and solely at heart the welfare of the seafaring population.

Dr. Hopkinson, F.R.S., thanked Sir William Thomson for the kind way in which he had spoken of his
